"The roof of the mouth is beefsteak red, and beefy and has a white exudate on it There are deep furrows The same picture is present on the sides of the cheeks and on the uvula The pharynx is red and 'angry looking' There is one small lesion on the gum over the left upper incisor"

An oral surgeon called in consultation stated The patient appears to have an inflammatory hyperplasia of the oral mucosa, very marked on the palate, with fissures I saw the patient at the suggestion of Dr John G Downing, who had seen the previous patient (case 2) at a meeting of the New England Dermatological Society and suggested that this patient probably had pyostomatitis vegetans The following is my consultation note

"Examination of the oral cavity shows a soft verrucous eruption of the hard and soft palate mucosa extending downward to include the uvula The mucosa of both cheeks shows folding in the molar regions but no active process at the present time Minute pinpoint whitish abscesses can be demonstrated in the lesions of the soft palate and uvula There are a few miliary abscesses in the upper part of the vestibule of the mouth in the cuspid regions The tongue shows an area of denudation of the coating, probably due to contact irritation from lesion of the palate The picture is strongly suggestive of a condition known as pyostomatitis vegetans"

Following is the report on the biopsy specimen taken from the palatal region of an old verrucous lesion

"The epithelial surface shows moderate hyperkeratosis and marked acanthosis with broadening of the rete pegs The underlying tunica propria shows a marked dense cellular infiltration with disorganization of the collagen fibers There is moderately increased capillary vascularization The cellular infiltration is very pronounced in the subepithelial zone and the papillas and extends into the epithelial surface forming dense collections of cells made up principally of lymphoid and plasma cells There is spongiosis of the acanthotic epithelium with many infiltrating lymphocytes extending to the surface epithelial layer The cellular infiltrate in the tunica propria is pleomorphic, with plasma cells predominating and relatively few polymorphonuclear leukocytes An occasional multinucleated cell is seen, and only a rare eosinophil is demonstrated The picture is that of a granulomatous inflammatory process of a chronic type The relative absence of eosinophils in this case as compared to the marked eosinophilia seen in early lesions can be explained by the age of the lesions The clinical picture together with the histologic findings indicates a chronic granulomatous process involving the oral cavity Two other cases of pyostomatitis previously seen by me differ only in that in more acute lesions the eosinophils predominate in the cellular exudate The diagnosis is pyostomatitis vegetans"

A report from the family physician received in November 1948 stated that there had been an improvement in the oral condition a year ago but that he had not seen the patient since that time

CLINICAL DESCRIPTION AND COURSE OF ORAL LESIONS

There was a remarkable similarity in the clinical courses in all 3 cases In cases 1 and 3 the disease was confined to the mouth throughout its entire course, and an opportunity to observe the primary lesions was presented in case 1 owing to a recent relapse after the mouth had been normal for three and one-half months

intraepidermal cavity with numerous eosinophils In the upper cutis the vessels are dilated and show swelling of the intima There is a diffuse infiltration of small round cells, wandering connective tissue cells, numerous eosinophils and occasional plasma cells"

Treatment has consisted of superficial irradiation, injections of arsenic and liver extract and blood and plasma transfusions Sulfapyridine was given, but its use had to be discontinued because of nausea and vomiting The last treatment given in the hospital and being continued in the clinic is administration of

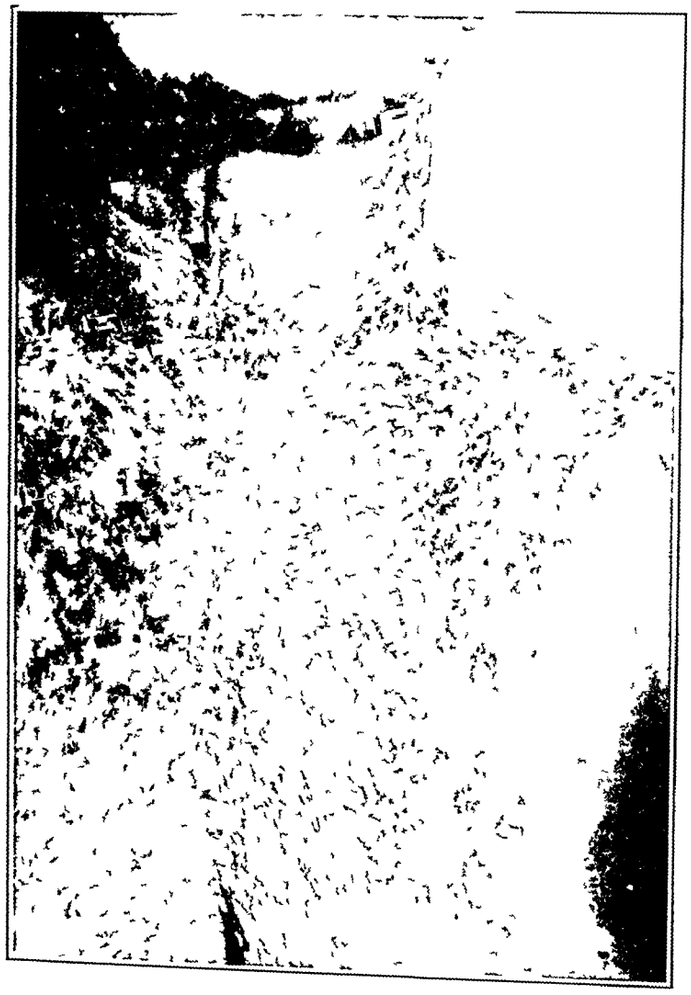

Fig 1—Vesicular eruption on neck and chest in a woman with questionable dermatitis herpetiformis

naphuride® in a dose of 0 25 Gm intramuscularly twice a week This seems to have benefited the patient

DISCUSSION

Dr Francis A Ellis, Baltimore Nausea is not a contraindication to the administration of sulfapyridine We have had severe cases in which we continued to use the drug in spite of nausea and vomiting, and even though the dosage was decreased, good results were obtained in three or four weeks

The primary lesions of pyostomatitis vegetans are noted as flat minute miliary abscesses on a slightly raised dark red inflammatory base The abscesses are uniform in size, suggesting early miliary tubercles, and tend to be more or less conglomerate, about 2 to 3 mm apart The process spreads within a very few weeks to involve the whole mouth, including the mucosa of the cheeks, the vestibule, the gingivas, the lingual aspects of the lips, the hard and soft palates and, to a limited degree, the margins of the tongue

As the condition develops chronically, the buccal mucosa begins to proliferate, is thrown into folds and assumes a verrucous appearance The miliary abscesses persist as fixed lesions and are found on the summits of the rugae and in the deep invaginations The mucosa is swollen, red and soft to palpation Under the dental plate in case 2 the miliary abscesses tended to rupture, leaving erosions with an accumulation of exudate becoming sticky from admixture with saliva This exudate could be peeled off, especially in the morning after inspissation from mouth breathing Smears from the miliary abscesses in the early stages show up to 30 per cent eosinophils and the remainder polymorphonuclear leukocytes

Only mild subjective symptoms occurred in each case, and the swollen verrucous lesions were not tender to the touch The verrucous mucosa acted as an insulating surface, and the ingestion of hot or spicy foods was not associated with any unusual discomfort In each case the course was relatively benign and of unusual chronicity with only slight periods of remission

The lesions of the oral mucous membrane were very distinctive and not simulated by those of any other oral disease

Although not a direct etiologic factor, the chronic diarrhea in 2 cases played an important role in lowering the resistance of both patients Both patients could be considered as below normal in their general health, and both had had recent acute infections, in case 2 the oral eruption appeared just after the attack of diarrhea had cleared up

The improvement in the oral disease in both cases was related to the use of liver and iron, together with prolonged vacations, rather than to any local treatment to the mouth

The cutaneous lesions in case 2 suggested an inoculation from the primary lesions in the mouth, but this was not proved The rapid spread of the vegetating cutaneous lesion of the groin was very striking and gave the clinical appearance of blastomycosis cutis The histologic picture was essentially the same as in the specimens removed from the mouth When the patient was hospitalized after three months of local treatment, the cutaneous condition responded to local antiseptic

Fig 1—Lesions of chronic discoid lupus erythematosus on the face

Fig 2—Lesions of chronic discoid lupus erythematosus in the upper half of the tattooed red heart on the left arm

treatment together with radiation therapy There has been no recurrence of the cutaneous lesions in case 2 after several months, although a residual palatal process still persists

It was the cutaneous eruption in case 2 which made it possible finally to clarify the diagnosis of the oral disease in all the cases

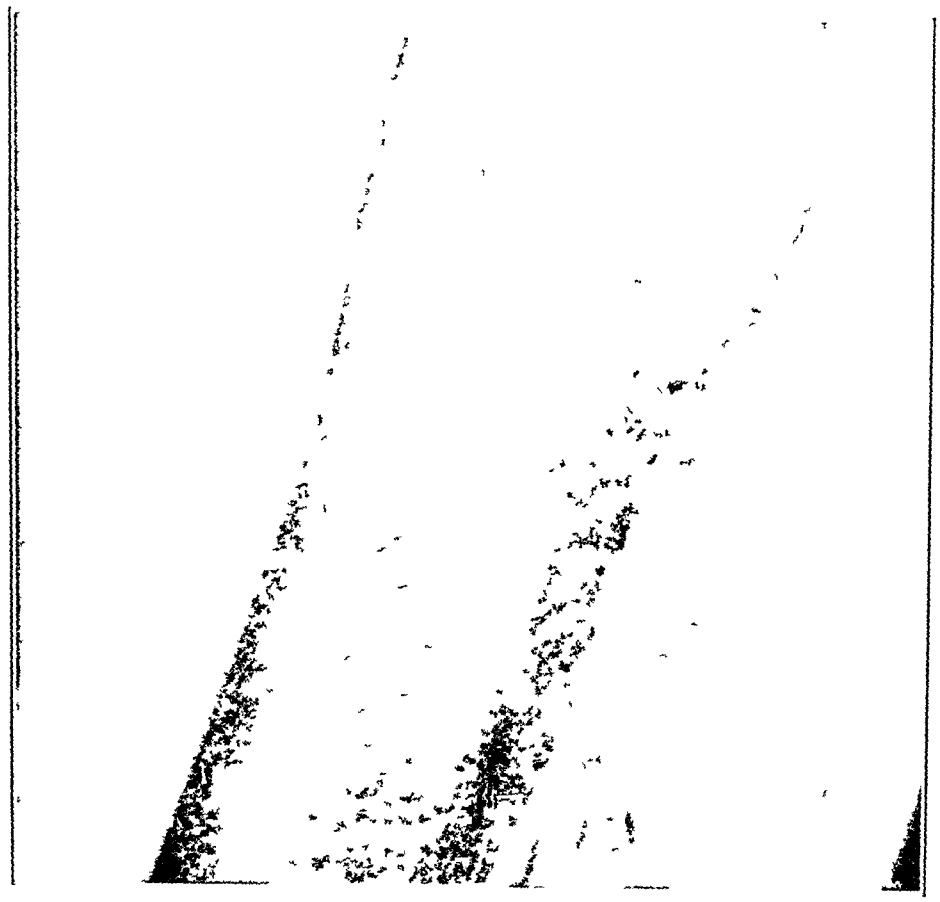
BACTERIOLOGY

Smears and cultures from the oral cavity were taken in all cases and also from the cutaneous lesion in case 2 The following report was submitted by Dr Ralph Wheeler, Department of Bacteriology, Tufts College Medical and Dental Schools

CASE 1—Fresh unstained preparations showed numerous pus cells, desquamated epithelial cells, a few red cells and no amebas The dark field was negative for spirochetes Smears showed gram-negative diplococci and short bacilli as the predominating organisms A few gram-positive diplococci were seen, but acid-fast organisms were not demonstrated Wright stain showed 11 per cent eosinophils, but no Leishman-Donovan bodies Vincent's organisms were not found. Cultures on blood agar plates and anaerobic cultures showed a variety of organisms consistent with the normal oral flora, the predominating micro-organisms being gram-negative diplococci, gram-positive micrococci, nonhemolytic enterococci, streptococci of the viridans group and a single colony of aerobic actinomycetes, probably a normal inhabitant

CASE 2—Essentially the same general bacterial flora was found as in case 1 A long gram-negative filamentous organism was found but not identified Saliva filtrate inoculated into the allantoic membrane of chick embryo produced no growth Cultures from the miliary abscesses from the lesion of the skin of the groin showed Staph aureus with a few colonies of hemolytic streptococci

CASE 3—The cultures from the lesions in the oral cavity showed the predominant organism to be a streptococcus of the viridans group There were no beta hemolytic streptococci found on culture



It can be concluded that these findings, together with the clinical course of the disease, indicate that the oral and cutaneous manifestations are not related to the micro-organisms demonstrated

PATHOLOGY OF ORAL AND CUTANEOUS LESIONS

Six biopsies in all were made from the oral lesions in all cases and one from the verrucous lesion of the skin in case 2

The general histologic pictures observed in these specimens were essentially the same The cutaneous lesions showed more pronounced hyperkeratosis with more extreme acanthosis and developed deeper invaginations of the surface epithelial layer. There was a more pronounced cellular infiltration with more numerous eosinophils in the upper part of the cutis and relatively larger miliary abscesses The oral lesions showed a marked acanthosis with broadening and elongation of the rete pegs with the epithelial surface thrown into folds, in places showing fairly deep invaginations Infiltrating eosinophil and poly-

of subcutaneous hemorrhage on both legs and thighs The oral mucous membranes were dry, and the submaxillary salivary glands were visibly enlarged, firm and of a rubbery consistency The parotid glands were affected similarly, but to a less degree Except for a slight hepatic enlargement and generalized superficial lymphadenopathy, the rest of the general physical examination showed no abnormality Examination with a slit lamp by the ophthalmologic consultant revealed many keratitic precipitates and deposits of pigment on the anterior capsule of the lens of each eye There were numerous clear grayish nodules on the anterior surface of the iris of each eye Moderate circumcorneal injection was present The ophthalomologic diagnosis was uveitis due to sarcoidal involvement, a condition which, in combination with the parotid swelling, could be classified as Heerfordt's disease (uveoparotid fever)

Lesions on patient's arm

Roentgenologic study revealed a mottled density in the lower field of the left lung and bilateral enlargement of the hilar nodes Reactions to the Mantoux test were negative with dilutions of 1 10, 1 500, 1 1,000, 1 10,000 and 1 20,000 History of a positive cutaneous reaction to a tuberculin test four years previously was later obtained from the patient Repeated examinations of sputum, gastric washings and cultures revealed no tubercle bacilli Except for an increase of the sedimentation rate to 47 mm, routine studies of the blood and urine revealed nothing abnormal The plasma globulin level was slightly elevated Serologic tests for syphilis were negative, as was the intracutaneous reaction to Frei antigen (lygranum) Microscopic study of cutaneous biopsy specimens by Dr M R Caro revealed moderate hyperkeratosis of the epidermis, with attenuation of the rete pegs There were focal perivascular accumulations of large mononuclear

morphonuclear leukocytes were noted in the deeper epidermal epithelium A very striking and distinctive picture was the presence of epidermal miliary abscesses with the predominating cell the polymorphonuclear coarsely granular eosinophil leukocyte Focal areas showing epithelial thinning with necrosis at the site of rupture of miliary abscesses were present The tunica propria showed a very marked cellular infiltrate, chiefly eosinophilic, especially in the region of the papillae Deeper in the specimens the cellular infiltration was slight to moderate In addition to the cellular infiltration of the tunica propria, there was considerable edema with increased capillary vascularity Proliferation of the endothelium in the young blood vessels was noted

The over-all picture was that of a granulomatous inflammatory process with unruptured miliary epidermal abscesses and focal areas of surface necrosis The tissue and blood eosinophilia was striking in 2 cases, although not diagnostic, as eosinophilic infiltration of tissue lesions and the presence of eosinophils in the peripheral blood stream are commonly observed in pemphigus vegetans, dermatitis herpetiformis and other dermatoses

DIFFERENTIAL DIAGNOSIS

When first seen and for several months afterward the disease involving the oral cavity remained undiagnosed, and it was only after the characteristic verrucous lesion of the skin in case 2 developed that a definite diagnosis was made

In pemphigus vegetans, oral lesions are characterized by a primary flaccid bullous lesion which contains a serous fluid tinged with blood These bullae rupture early, leaving superficial painful eroded areas New lesions continue to form, and the oral condition presents a characteristic appearance Desquamated epithelium and a fibrinous exudate frequently coat the superficial ulcerations In very chronic oral involvement, focal areas of proliferating granulation tissue may develop but the process is very painful

In the very rare oral disease oral pemphigus, in which the lesions are confined to the mouth, the primary lesions are also bullous and the process may continue for years Extension to the pharynx may occur in these cases, and pain is a prominent symptom

Dermatitis herpetiformis has been described as a disease that may cause cutaneous lesions similar to those described in pemphigus vegetans Oral involvement in dermatitis herpetiformis has been described, with lesions essentially the same as in pemphigus vegetans However, many dermatologists state definitely that the mouth is not involved in this disease, and I have never seen a single case of dermatitis herpetiformis with oral lesions

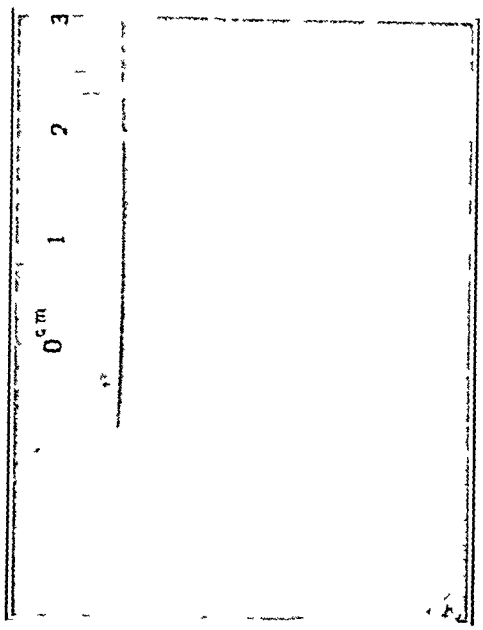


Fig 1—Nodular lesions in the cubital area appearing after an intravenous injection of calcium levulinate

Fig 2—Photomicrograph (× 100) showing foreign body tubercles with giant cells and deposits of calcium

Lupus erythematosus not infrequently shows buccal lesions which tend to ulcerate early and usually are associated with subjective symptoms of pain and soreness, although some patients are relatively free from pain The lesions are sharply defined and their appearance varies with the age of the lesion The common locations are on the lips and in the vestibule of the mouth, especially in the molar regions The palate and gingivas, together with other locations, may be involved The lesions in the beginning are bright red plaques with slightly infiltrated borders, with thinning of the centers as the lesions progress Many of these lesions as they heal resemble those of leukoplakia

Eosinophilic granuloma,[18] regarded by many as an entity, has in recent years been described in the dermatologic literature The complexity of the clinical picture and a more specific histologic picture help to differentiate this condition from the oral and cutaneous lesions of pyostomatitis vegetans To date there has been no mention of oral lesions in all the cases of eosinophilic granuloma reported in the literature

TREATMENT

As indicated in the description of these cases, local therapy had no effect in clearing up the lesions Local and parenteral administration of penicillin and oral administration of sulfonamide drugs had no beneficial effect on the mucosal lesions Use of iron and liver together with prolonged vacations was effective in aiding the return to normal of the buccal mucosa in case 1, and in case 2 a similar result was accomplished except for a residual process on the palate after twenty-two months In case 3, according to the most recent report, in 1947, there was improvement in the oral condition with a residual process still persisting in the palate region

SUMMARY

Three cases of a rare vegetating oral mucosal disease are described in 1 of which typical pyodermatitis vegetans developed, in the others the condition remained as an oral entity

Pyostomatitis vegetans presents a characteristic and distinctive oral disease with primary miliary abscesses on an inflammatory base with the development of verrucous changes

The clinical course in 2 cases was confined to the oral cavity, these are the only cases reported in the literature in which the disease remained an oral entity

NONLIPID GRANULAR CELL TUMORS

HAROLD N COLE, M D
AND
HERBERT LUND, M D
In Collaboration with H N Cole Jr, M D, J R Driver, M D, Richard C Light, M D, and Don R Printz, M D
CLEVELAND

NONLIPID granular cell tumors are usually considered to be myoblastomas, and in the following review this term will be used freely However, identity of all these tumors is still open to question We present 3 cases exemplifying this problem

In 1926 Abrikossoff [1] reported a tumor of myoblasts occurring chiefly in relation to striated muscle He thought it might be due to degenerative lesions following injury or inflammation In 1931 [2] he further elaborated his ideas on myoblastic myomas, as he called them, feeling that perhaps they were made up of embryonal elements primitive myoblasts He divided them into four different types, of which the first three are all granular cell and benign (1) round, egg-shaped or elongated myoblasts, 20 to 25 microns in length, showing granules but no longitudinal or cross striations, (2) growths in which some of the cells may show longitudinal or cross striations, and (3) a hypertrophic form with cells 40 to 160 microns in length and at times multinucleated. He also described a further type (4), in which the myoblasts are not granular but atypical, which resembles more a polymorphous sarcoma

Crane and Tremblay,[3] in reporting 5 cases in 1945, pointed out that, although Abrikossoff had reported 5 cases in 1926, Weber in 1854, Hertaux in 1881, Pendel in 1897 and Moschcowitz in 1922 had described what were apparently identical lesions Crane and Tremblay reviewed

Read at the Sixty-Eighth Annual Meeting of the American Dermatological Association, Inc, San Diego, Calif, April 28, 1948

From the Department of Dermatology and Syphilology and from the Institute of Pathology of the Western Reserve University School of Medicine and of the University Hospitals

the literature, which up to the time of their publication consisted of 162 cases, 34 of the skin and subcutis and 61 of the tongue

In the past few years there has been much more interest directed to this group of tumors, with quite extensive reports, among others those by Klemperer,[4] Howe and Warren,[5] Ravich, Stout and Ravich,[6] Powell[7] and Khanolkar[8] Reports on the disease, as it has become better known, have mounted rapidly, thus Powell reported 4 cases in 1946, Simon,[9] 6 in 1947, Khanolkar, a further 10 in September 1947, and Allen,[10] 27 in 1948 The total, including Bloom and Ginzler's,[11] Cipollaro and Einhorn's[12] recent cases and our 3 cases, is around 214 cases It is our view that as the entity becomes better known and as the physician becomes more inclined to examine lesions histologically, granular cell myoblastoma will be found to be far from a rare entity Thus Allen found 27 myoblastomas in material from 8,000 specimens of cutaneous diseases collected in World War II by the Army Institute of Pathology

LOCALIZATION AND CHARACTERISTICS

These tumors seem to be found most frequently on the tongue and in the mouth and larynx, in about some 37 per cent of the cases The growths have been distributed all over the body and in some internal organs

Strangely enough, the occurrence of these tumors in the second most frequently involved area, the skin and subcutis, has not been sufficiently emphasized until in the very recent literature Powell in 1946 stated that 20 4 per cent of the cases so far reported had involved these structures In 3 of her 4 cases the cutaneous surfaces were affected—

in 1 with multiple lesions Tuta and Schmidt[13] in 1942 reported 3 examples of cutaneous involvement and 1 of the trapezius muscle Ebert and Slepyan[14] the next year presented a patient before the Chicago Dermatological Society with a small nodule on the dorsum of the left hand In the discussion Becker[15] stated that he had recently seen in consultation with Dr Clarence Shaw a similar tumor on the upper part of the chest Then Bloom and Ginzler reported the case of a Negro woman with a hazelnut-sized, round, raised tumor of the lip which, after endothermy, was followed two years later by a hazelnut-sized nodule of the skin and subcutis of the right thigh, a similar lesion on the trunk and a smaller one on the right hip Very recently Cipollaro and Einhorn observed a marble-sized nodule of the right index finger as well as one on the tongue There have been a few instances reported of polyp-like masses in the ear canals, which growths may attract attention by bleeding

These tumors are very often symptomless, are many times sessile and vary in size from 0 5 to 2 0 or 3 0 cm , occasionally being even larger Their color on the mucous membrane is often described as grayish or opalescent In Ebert and Slepyan's case the quarter-sized mass was made up of several smaller nodules Rarely are the growths painful unless in a vital structure and ulcerating as well The patients vary from newborn babes with small lesions of the alveolar processes up to persons in the second, third or fourth decade of life, rarely older

MICROSCOPIC APPEARANCE

These tumors are generally well circumscribed, ovoid or lobulated and rather firm Occasionally the borders may show outlying islands of cells and may even penetrate surrounding tissues The growths are made up of rather large, elongated or polyhedral cells, appearing as single cells or in sheets They may have a banjo or tadpole shape or the shape of a tear drop, as has been mentioned by many writers And some tumors will show a striking pseudoacinar appearance of the cells They have a coarse, granular cytoplasm, acidophilic in character, and nuclei that are comparatively small and have an angular appearance In some cases the cells may be multinucleated The cytoplasm is often foamy, resembling somewhat that of a xanthoma cell However, it does not have the tinctorial reactions of the latter Occasionally the cells

15 Becker, S W , in discussion on Ebert and Slepyan[14]

in certain tumors will show suggestions of longitudinal or cross striations Keynes [16] and Klemperer pointed out the interesting feature of overgrowth of the overlying epithelium where the skin or mucous membrane is concerned—a pseudoepitheliomatous hyperplasia This condition was striking in the cases of Bloom and Ginzler, even to the production of pearls, which the pathologists interpreted as indicative of a low grade squamous cell carcinoma

MALIGNANT GRANULAR CELL TUMORS

Originally, Abrikossoff separated a fourth group of tumors resembling more a polymorphous sarcoma, which is quite generally not included in the classification of granular cell myoblastomas Howe and Warren reported that they had seen 10 cases, among which there were 5 with definite malignant properties, 3 of the growths metastasizing to the lung They also stated that they had found 10 cases in the literature and 4 of their own with either gross or microscopic evidence of local invasion There had been regional adenopathy in 7 cases, but in only 3 were metastases to lymph nodes proved by biopsy In none was there response to irradiation Ravich, Stout and Ravich expressed the opinion that all 5 of their cases should be put in Abrikossoff's fourth class They were skeptical of the malignant character of this tumor until the occurrence of their own case, in which a tumor of the bladder recurred after excision and in which the patient died eleven months later from metastases They stated the belief that their case is the first example of a type 3 tumor metastasizing and causing death However, in Morpurgo's [17] case the patient, with a tumor of the tongue, died with metastases in the cervical nodes In Powell's patient 3, who had a large growth in the floor of the mouth, displacing the tongue, there was invasion of the tissues and death from erosion of a vessel Moreover, in her case 4 there were tumors in the scalp, the upper eyelid, the lower lip, the right axilla, the right side of the torso, the left thigh, the vulva, the back, the toe and the buttock, as well as of the uterus and an ovary After removal of some of these, including the uterine and ovarian growths, further growths developed on the skin This development of further cutaneous lesions also occurred in Bloom and Ginzler's case after partial removal of the tumor of the lip Moreover, Khanolkar, in a recent article, reported a further 10 cases in which there could be no uncertainty regarding the neoplastic nature These

16 Keynes, G Rhabdomyoma of Tongue, Brit J Surg **13** 570-572 (Jan) 1926

17 Morpurgo, B Myoblastomi, Arch per le sc med **59** 229-252 (Feb) 1935, cited by Bloom and Ginzler [11]

data, we think, force one to believe that at times granular cell myoblastoma may be malignant Ewing[18] expressed the opinion that most myoblastomas are benign

ORIGIN

Originally the theory was evolved that these tumors were degenerative lesions following injury or inflammation or that they arose from embryonal muscle cells Gray and Gruenfeld[19] stated the belief that the evidence for the theory is insufficient except for the tongue tumors The frequent appearance of the growths on the tongue has suggested the possibility of trauma This possibility was also suggested in Khanolkar's case 1, which followed a fall Crane and Tremblay in 1945 stated that "Definite statement as to the histiogenesis of these tumors is probably unwise at this time" Perhaps this opinion represents good judgment for the present

TREATMENT

As to their treatment, practically all authors agree that these tumors are not amenable to radiotherapy If they are recognized, it would seem to be good judgment for one to excise them, widely, if possible Otherwise, it would be well, if possible, for one to excise the growth and cauterize the base, if the lesion is small

The information concerning these tumors certainly suggests to dermatologists and surgeons the more frequent adoption of biopsy, otherwise many of them will not be recognized

CASE 1—N M, aged 71, a retired Naval officer, was admitted with the complaint of a sore on the tongue, of three weeks' duration

The patient had been a heavy pipe smoker for many years and had but recently noticed this spot on the tongue He did not remember having bitten himself

Physical examination revealed on the left side of the tongue, about halfway back and slightly toward the ventral aspect, a small, somewhat indurated, pearly white lesion, about 6 mm in diameter The area was slightly tender

With the use of local anesthesia the entire lesion was widely excised for biopsy and the base thoroughly destroyed with electrocautery The patient has been followed for two years and shows no evidence of recurrence of the lesion

The histologic report stated that the paraffin section stained with hematoxylin and eosin included buccal mucosa, a zone of atypical cells and underlying skeletal muscle The mucosa was hyperplastic, and irregular pegs extended deeply There was keratinization of groups of the deeper cells The cells were mature Mitoses in the epithelium were rare There was slight parakeratosis Pseudoepitheliomatous proliferation was striking

18 Ewing, J Neoplastic Diseases A Treatise on Tumors, ed 4, Philadelphia, W B Saunders Company, 1940

19 Gray, S H, and Gruenfeld, G E Myoblastoma, Am J Cancer **30** 699-708 (Aug) 1937

Atypical cells extended from the inferior border of the epithelium, with which they were in immediate contact, to the underlying skeletal muscle They formed a broad sheet within which were occasional slender septums of connective tissue cells and capillaries Deeply, they mingle with the muscle fibers There were groups consisting in part of striated muscle fibers and in part of atypical cells The diameter of the atypical cells was larger than that of the muscle fibers, but these cells had the same general shape and had sharply outlined boundaries The cytoplasm was pale and finely granular and occasionally contained acidophilic clumps, in some instances they formed fine, parallel, linear, closely arranged, fibrillar lines Cross striation was not identified The nuclei were small but

Fig 1 (case 1) —Myoblastoma of the tongue, with pseudoepitheliomatous hyperplasia of mucosa, × 86

tended to be larger and more rounded than those of normal striated muscle They showed faint, weblike chromatin and, occasionally, a pale pink dot resembling a nucleolus Mitoses were not seen The atypical cells appeared to extend beyond the deep margin of excision

A frozen section showed no sudanophilic droplets in the cells

CASE 2—V B, a Negro woman aged 41, was first seen in April 1946, complaining of a small lump on the left side of her tongue The mass had been first noticed one year previously, was asymptomatic and had been slowly enlarging

The history, except for that of syphilis, which had been well treated, was not relevant

On the left lateral border of the tongue, midway between the tip and the base, was a well defined, very firm, nontender tumor This measured 0 8 by 0 7 by 0 5 cm, was almost white and had a rough, somewhat verrucous surface Other oral mucosae were normal, but the teeth were extensively carious

Fig 2 (case 2)—Myoblastoma of the tongue, superficial part of tumor, with pseudoepitheliomatous hyperplasia, × 86

The entire lesion was widely excised and the base thoroughly cauterized Eighteen months later the patient was entirely cured

Histologic examination revealed this section to be almost identical with that for case 1 The atypical cells had the same distribution and appearance It was noted that some cells showed a mixture of appearances, in part resembling normal sarcoplasm At the periphery or at one side the cytoplasm might be

brightly eosinophilic and compact, as in normal striated muscle cells, while centrally or at an opposite side it was loose, pale and granular Cells of intermediate intensity of staining were also present They had loose fibrils and faint cross striations and resembled skeletal muscle except that they were larger and paler No mitoses were present The atypical cells extended to the depth of the section The epidermis was similar in every respect to the section from case 1

Fig 3 (case 2) —Myoblastoma, deep portion of tumor, in which may be seen mixture of the granular cells with the striated muscle of the tongue, × 134

There was more parakeratosis, however, and an extreme pseudoepitheliomatous hyperplasia

CASE 3[20]—L S, a man aged 40, had had a gradually developing tumor in the anteropalmar aspect of the distal phalanx of the right thumb for four years

20 Included through the courtesy of Dr J M Hamilton and of Dr D J Rehbock, clinical pathologist, St Vincent Charity Hospital

The tumor was freely movable and completely painless There was a history of catching the thumb in a door jamb and pinching it severely some months before In fact, the injury had been so severe that the patient had only a spoon nail on that digit. His occupation was not relevant

The tumor was only recently excised through an incision of the skin without removal of skin There were no other lesions

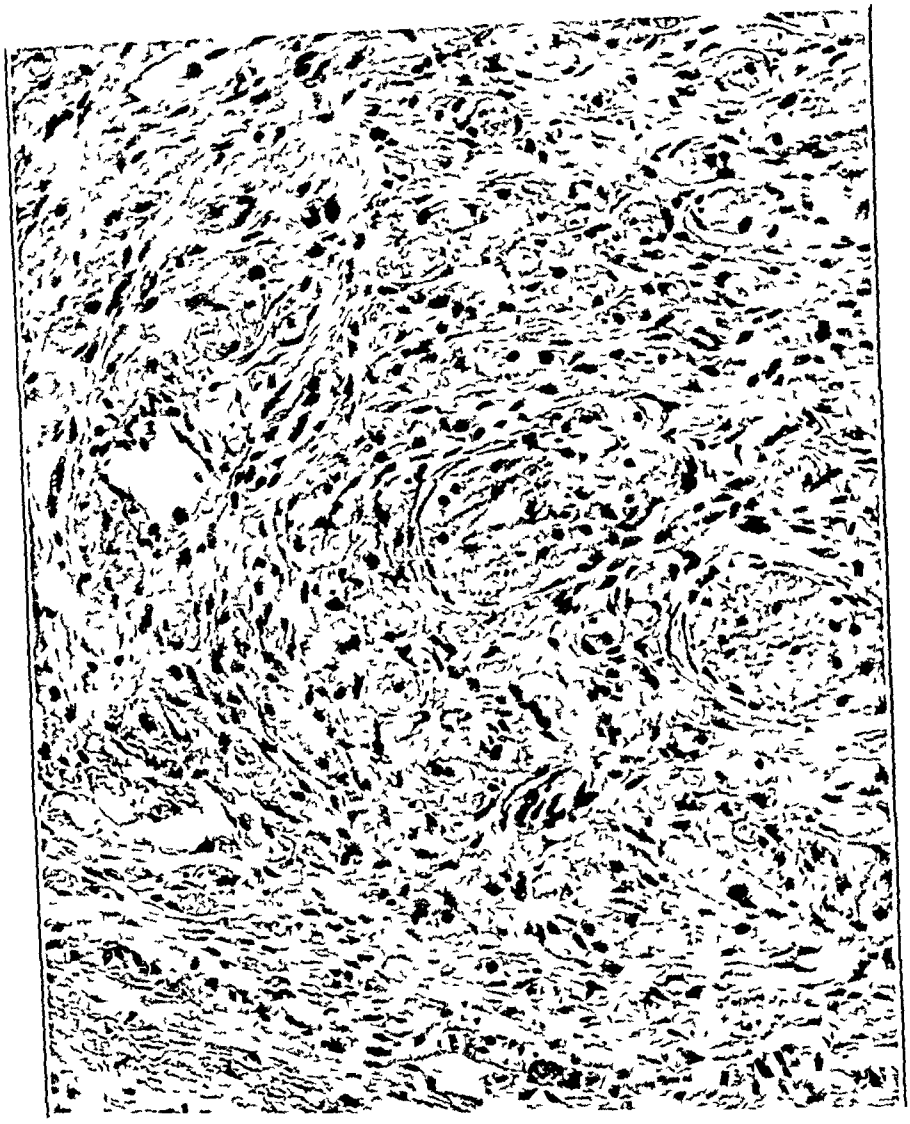

Fig 4 (case 3) —Granular cell tumor of finger, with coarse granularity of cells, about × 200

The specimen consisted of an ovoid, firm, pearly gray tissue mass, measuring 1 0 by 0 6 cm The surface was lobulated but otherwise smooth Section revealed a firm, fibrous, pearly gray tissue

The paraffin section stained with hematoxylin and eosin consisted largely of rounded groups of atypical cells enclosed by a circle of fusiform cells and hyaline fibers These groups were in turn collected and held together by interlacing bands of hyaline fibers, and the entire mass was bounded by collagenous tissue on two sides Outside of this capsule were a little areolar tissue and a few sweat glands The other two sides were cut surfaces

The atypical cells were round and polyhedral or long and cylindric They were granular and moderately eosinophilic The granules were fine, although a few coarse hyaline clumps were seen Indistinct cross markings were seen Some of these appeared as very fine basophilic lines, and others had an appearance produced by parallel arrangement of granules Some nuclei were basophilic, compact and small Others were larger and showed a reticular and punctate chromatin pattern Single or multiple nuclei might be seen in a single cell Where cells were longitudinally cut, spaced nuclei might be seen in a row Mitoses were not present

COMMENT

In the two lingual lesions there were transitions from striated muscular cells to granular atypical cells (fig 3) It is reasonable to conclude that for these the term myoblastoma is justified

In case 3, however, there were differences The cells were larger and more coarsely granular, and there was grouping in round nests, in contrast to the uniform sheets found in the lingual lesions Muscular relations were not seen Further, the tumor arose in a site away from normally situated skeletal muscle The histologic diagnoses entertained were myoblastoma, traumatic pseudoneuroma and neurofibroma The first-mentioned one seemed the most likely

At this juncture the presentation of Fust and Custer [21] concerning granular cell neurofibroma was heard, and the slide was sent to them for an opinion They expressed the opinion that it was an example of granular cell neurofibroma

Without further study concerning the nature of these tumors, and pending the publication of Fust and Custer's work, we choose to call the lesion a granular cell tumor and to be noncommittal concerning its origin

SUMMARY

A report is made of 2 cases of granular cell myoblastoma of the tongue and of a subcutaneous granular cell tumor of the thumb They are discussed from a clinical and microscopic standpoint

Such tumors are probably much commoner than is suspected

The tumors are found most frequently on the tongue and in the mouth and appendages, they are seen next most frequently on the skin and subcutis

While in most cases these tumors are not malignant, nevertheless sufficient reports are accumulating to indicate that in certain locations and under certain conditions invasion, metastases and death may result from less than total surgical removal The tumors are highly radioresistant

21 Fust, J A, and Custer, R P The Neurogenesis of So-Called Granular Cell Myoblastoma, Am J Clin Path **19** 522-535 (June) 1949

There are a few cases in which these growths have been multiple in type on the skin and subcutis as well as in internal organs

In tumors of the skin and mucous membrane, the pseudoepithelioma-tous hyperplasia is frequent enough to be noteworthy

The tumors of the tongue strongly suggest muscular origin Other tumors without demonstrable transition from or location in muscular tissue are more obscure The work of Fust and Custer is anticipated

ABSTRACT OF DISCUSSION

Dr Hamilton Montgomery, Rochester, Minn I have been interested in myoblastoma ever since Dr Machacek called my attention to this condition several years ago when the American Academy of Dermatology met in New York A fellow in pathology at the Mayo Clinic, Dr G H Murphy, just finished studying 10 cases which he classified under the headings of the uniform type of myoblastoma, which is benign, and the pleomorphic type, which is essentially a rhabdomyosarcoma The granular cells appear in both types I had formerly accepted the concept that granular cell myoblastoma arose from skeletal muscles Recently, however, I have seen 2 cases in which there apparently was origin from smooth muscles In 1 case there was a lesion on the vulva of a Negro woman aged 72, which showed smooth muscle origin Material from a recent case with involvement of the anal region, sent to me by Dr Wasserman of Cincinnati, showed granular myoblastoma cells apparently arising in relation to the walls of the capillaries in the papillary bodies This observation would suggest endothelial origin, because these capillaries are not supposed to have a muscular coat In some of Murphy's cases of the pleomorphic type, there was a history of trauma preceding the development of the tumor and subsequent metastasis and death Myoblastoma does not have a typical clinical appearance but does have a characteristic histologic one

Dr Anthony Cipollaro, New York My attention was brought to this disease several years ago when a patient came to my office with a small lesion on the tongue I diagnosed it as a fibroma I was going to infiltrate it with procaine hydrochloride (novocain®) and destroy it with electrodesiccation, but, because the man was worried about cancer, I removed the tissue and submitted it for biopsy The type of lesion was not recognized by the first dermatopathologist It had unusual cells with which I was not familiar Dr Richter, a general pathologist, immediately diagnosed it as a granular cell myoblastoma This case was published by me a few months ago in the Archives [12]

I think that all nodular lesions of the tongue should be removed and submitted to the laboratory for histologic study

Dr. Louis Winer, Hollywood, Calif Recently my associates and I had submitted to our laboratory a piece of tissue which showed myoblastoma The differential stains were very interesting Van Gieson stain colored the blastoma tissues yellow, like smooth muscles Mallory's stain showed the tissue to be bright red, just as it does muscle fibers Therefore, I would advise that differential staining be done In the case of neurofibromatosis, also, differential stains would be of benefit because the tissue in neurofibromatous structure is mostly fibrous and stains like connective tissue, red with Van Gieson and greenish blue with Mallory's stain

DR HARRY ARNOLD JR, Honolulu, Hawaii I should like to mention in this connection an instance of a small lesion on the side of a young woman's neck, clinically an obvious granuloma pyogenicum, which was sectioned in our laboratory purely as a routine matter and turned out to be an infiltrating, anaplastic, granular cell carcinoma, the cells of which were full of fat It was an example of the sort of lesion Dr Cipollaro spoke of, which is all too frequently merely thrown away after its removal Excision of the operative site the following afternoon revealed a nest of residual neoplasm

DR HAROLD N COLE, Cleveland Thank you all for the discussion I mentioned a classification of these tumors containing four groups The fourth group is that of a nongranular polymorphic sarcoma, generally not accepted as a granular cell myoblastoma, and should be deleted

USE OF REPELLENTS IN CLINICAL DERMATOLOGY

General Principles

LEON GOLDMAN, M D
CINCINNATI

AMONG the advances in preventive medicine in the last world war were the detailed studies in the chemical control of insects As yet, the practicing physician, as compared with the military physician does not appear to be fully aware of the possibilities for the control of insects, especially the disease-bearing types This chemical control, in general, falls into two phases insecticidal and repellent activity

The development of insecticides is well known from the advances in the preparations of pyrethrins and DDT (2,2-bis [p-chlorophenyl]-1,1,1-trichloroethane) and its newer analogues, such as DDD (1,1-dichloro-2,2-bis-[p-chlorophenyl]-ethane) and methoxychlor (1,1,1-trichloro-2,2-bis [p-methoxyphenyl]-ethane Perhaps less is known about the developments of new insecticidal materials, which include such substances as gammexane® (hexachlorocyclohexane), velsicol 1068® (also called chlordan), hexaethyltetraphosphate, piperine compounds, parathion (0,0-diethyl-0-p-nitrophenyl thiophosphate), very toxic, phenyl cellosolve® (ethylene glycol monophenyl ether) and eura® (10 per cent crotonyl-N-ethyl-ortho-toluidide) [1] Dermatologists should be interested also in the development of effective modern rodenticides, such as 1080, alpha-naphthyl-thiourea, and fanyline

Repellents have a distinct and important value because they serve, by means of a protective cloud of volatile products about the person, by taste mechanisms, by physical or mechanical means, etc, to keep insects away Repellents are necessary, for it may be possible for one to be bitten during the latent period of activity of an insecticide At present, it is not possible to combine in a single universally effective mixture both insecticidal and repellent properties Prior to World War I, few, if any, effective repellent materials were available Smokes and oil of citronella were old favorites During World War II thousands of compounds [2] were tested, and continued to be tested, for their repellent and toxic qualities against mosquitoes, lice, mites, ticks and "other

From the Department of Dermatology and Syphilology of the University of Cincinnati College of Medicine

1 Heyroth, F Personal communications to the author

2 Travis, M, and Cochran Insect Repellents Used as Skin Treatment by the Armed Forces, J Econ Entomol **39** 637, 1946, Chem Abst, vol 41, no 2207

arthropods affecting the health of man" [3] The brilliant researches of the various governmental groups are especially known by the studies on DDT However, equally important work has been done, and continues to be done, especially by the Bureau of Entomology and Plant Quarantine of the Agricultural Research Administration, in the investigation of repellents Effective mixtures, well known to military physicians, were the dimethylphthalate solutions and the dimethylphthalate combined with hexanediol and indalone® (butyl ester of 3,4-dihydro-2,2-dimethyl-4-oxo-1,2-pyran-6-carboxylic acid) Toward the end of the war, Pijoan [1] and Jachowski,[1] working at the Naval Medical Research Institute, developed the NMRI-448 repellent This compound represents the four hundred and forty-eighth attempt to find an effective repellent mixture, which essentially was the combination of 70 per cent 2-phenylcyclohexanol and 30 per cent 2-cyclohexylcyclohexanol Jachowski [1] claimed that NMRI-448 is superior to the 612 and the 622 mixture in effectiveness against the mosquitoes of tropical America and of equal effectiveness against the mosquitoes of the United States and Alaska Recent work has indicated that N-propyl-N,N-diethylsuccinamate has also good repellent action when applied to the skin Recent work by Brennan [3] has also included the development, especially as a repellent for ticks (Dermacentor andersoni, Amblyomma americanum), of phenylcyclohexanol and butylacetanilide Our preliminary studies with N,n-butylacetanilide indicate that this material is also of low sensitivity index

With regard to the protection of the person, the two significant features of repellent activity are, first, the limitation of the protection to the area or areas to which the repellent has been applied and, second, the duration of activity of the repellent action In general, the repellent mixture in a suitable vehicle may be used locally on the skin, or clothing may be impregnated with it The duration of the activity varies with the type of repellent, and perhaps with the type of vehicle The recent development in the use of repellents has increased the time of repellent activity to approximately eight hours for the NMRI-448 group Clothing impregnation prolongs the period of repellent activity Against ticks, the repellent activity is said to last as long as twelve days

Repellents in dermatologic practice are useful specifically in preventing chigger infestation and bites, mosquito bites, fly bites and flea bites, they act as a tick repellent and possibly are of value in management of the familial infestations pediculosis and scabies

Protective clothing and various types of sulfur preparations have been used to prevent chigger (genus Trombicula) infestations In

3 Brennan, J M Preliminary Report on Some Organic Materials as Tick Repellents and Toxic Agents, Pub Health Rep **62** 1162, 1947

recent years, I have used benzyl benzoate preparations on the lower extremities as a protective measure King has indicated that for uniform impregnation against chiggers these five new compounds are all superior to benzyl benzoate, benzyl, 2-thenyl benzoate, p-cresyl benzoate, diphenyl carbonate and 2-thenyl salicylate The modern repellent for the prevention of chigger bites are rubbed in from the ankle to the knee, they are also put into the cuffs of trousers, clothing may be impregnated and the substance rubbed into shoes The technic of this application refers to protection of the person only while he is walking through chigger-infested areas, for sitting or lying in the grass, however, greater areas of the body must be protected Besides the usual severe discomfort from these bites, significant reactions may occur in the elderly, in persons with latent and actual stasis syndromes and in infants and young children with extensive bites Parkhurst [1] emphasized repeatedly the necessity of preventing bites from the chigger For the use of repellents against flying insects, such as flies and fleas, the repellent must be used on the exposed areas of the skin Such areas include chiefly the head, neck, neck line, wrists, arms and trouser line It should be remembered that the repellent must be reapplied if the supposed period of activity has been exceeded When repellents are mixed in "sun tan mixtures," one must consider the possible insect-attracting qualities of these mixtures

For those insects which serve as vectors for disease, such as ticks, mosquitoes, simulia and flies of the Phlebotomus group, these repellents have an importance far beyond the prevention of the mere initial cutaneous bite In a previous report,[4] the relation of the lichen urticatus syndrome in children to bites from insects was shown For those children, repellents are needed, especially against fleas, chiggers and bedbugs Tick repellents also may be applied to the skin or the clothing impregnated Although repellents should have value in familial infestations with Phthirus pubis, Pediculus capitis and Sarcoptes scabiei, few controlled studies on civilian groups are available In practice, actual antiparasiticidal treatment of the entire family, especially in the case of scabies (scabies domestica), is carried out, and the repellents, though less irritating, are not needed

The mixtures of repellents that were developed by the armed services during the war have undergone, in addition to severe critical laboratory use and field trials, controlled tests with regard to systemic

4 Goldman, L Lichen Urticatus Syndrome as a Manifestation of Sensitivity to Bites from Various Species of Arthropods, Arch Dermat & Syph **58** 74 (July) 1948 Draize, J H , Nelson, A A , and Calvery, H O The Percutaneous Absorption of DDT (2,2-Bis [p-Chlorophenyl] 1,1,1-Trichlorethane) in Laboratory Animals, J Pharmacol & Exper Therap **82** 159, 1944

toxicity and cutaneous irritation and sensitivity As an example, to develop a technic of screen testing for rapid elimination of those compounds which would be harmful to man and animals, Draize, Nelson and Calvery [4] devised a detailed percutaneous toxicity test on animals The materials that are available now, as a result of such extensive cooperative work, are mixtures with a low sensitivity index

From experience, it appears that the discomfort suffered with the use of repellents is usually caused by its vehicles, alcohol or other solvents, rather than by the repellents themselves It is the solvent that is responsible for the burning around the eyes and mouth and on active sunburned areas For some time cream vehicles, with a content of liquid repellent varying from 10 to 60 per cent, have been suggested by the Orlando Florida Laboratory of the Bureau of Entomology and Plant Quarantine of the Agricultural Research Administration In general, a cream type of vehicle is preferable

Persons traveling to tropical or subtropical areas should receive, in addition to their protective inoculations, simple and practical instructions regarding the modern uses of insecticides and repellents The dermatologic aspects of modern insecticides will be reported in another article

CONCLUSION

Greater use should be made by the civilian dermatologist of the recent advances in the chemical control of insects Repellents are of value for the prevention of bites, especially in the case of persons who are sensitive to bites of the mosquito, fly, flea, chigger (Trombicula) and the tick Persons traveling in foreign countries and in tropical or subtropical areas should be instructed in the chemical control of insects This instruction is as important as the detailed inoculation program The activity of the repellent is limited to the area or areas protected and by its duration Repellents may be used in liquid or in cream form, or the clothing may be impregnated The repellents available now are materials of low sensitivity index

University of Cincinnati

Clinical Notes

PROGRESSIVE DISSEMINATED COCCIDIOIDOMYCOSIS

WERNER W DUEMLING, M D
SAN DIEGO, CALIF

In 1892 Wernicke[1] and Posada[2] reported the first known case of coccidioidal granuloma Two years later Rixford[3] described the first case in the American literature At that time the causative agent was considered to be a protozoan, because of the resemblance of the indolent ulcers of the skin in this disease to those produced in animals by coccidia, the name of coccidioides was suggested for this agent In 1900 Ophuls[4] recognized and described the causative agent as a moldlike parasite which was readily cultured on various mediums It has been within the last decade that valley fever, the syndrome of influenza and erythema nodosum, has been attributed to coccidioides[5] This recognition of the primary infection has caused a considerable change in attitude toward the disease Coccidioidal infection, once considered a rarity when recognized only in the granulomatous stage, is now not uncommon, however, the extensive and unusual involvement in the following cases which came under our observation merits reporting in detail

REPORT OF CASES

CASE 1—A M R, a 32 year old Mexican Indian, entered the United States Naval Hospital, Treasure Island, San Francisco, on April 8, 1944, complaining of a painful right ankle and sores on his skin He was born in San Diego and prior to his enlistment in the Navy on Dec 13, 1943, had lived in San Diego county

On March 15, 1944, a nodule developed on his left forefinger and his right ankle became painful Several days later nodules appeared on the left cheek and on the right side of the forehead These nodules were at first small, reddish purple and smooth-surfaced but later became verrucous and elevated, with a purulent discharge

The physical examination revealed a small, thin man in no distress, with purulent verrucous nodules on the left forefinger, right side of the forehead and the left cheek (fig 1) There was widespread lymphadenopathy and a warm, tender, swollen right ankle The examination revealed no further abnormalities

5 Dickson, E C Coccidioides Infection, Arch Int Med **59** 1920 (June) 1937, Valley Fever, California & West Med **47** 151 (Sept) 1937

The erythrocyte sedimentation rate was 30 mm per hour, and the white cell count was 7,750, with 6 per cent eosinophils The reaction in the coccidioidin skin test was positive Aspirated pus from fluctuant cervical lymph nodes contained the double-contoured highly refractive spores characteristic of coccidioidomycosis The early lesions became granulomatous, and new abscesses developed in the left knee, the left buttock, the left portion of the thorax and submental region The diagnosis was verified by culture, biopsy and guinea pig inoculation The lesions were treated by drainage and excision, and potassium iodide was given orally, with little or no improvement On May 5 the patient was given a course of penicillin extending over a seven day period and totalling 1,000,000 Oxford units, with no appreciable change Roentgenograms on August 23 revealed parenchymatous infiltration of the subclavian portion of the right lung and destruction of the bone of the left seventh rib, all previous roentgenograms had shown no abnormalities Treatment with coccidioidin vaccine, at first a stock supply and later an autogenous

Fig 1—*A*, noduloulcerative lesions of the face *B*, detail of lesion on left cheek, showing close resemblance to blastomycosis

vaccine, was started on July 18, 1944 and continued at two week intervals The patient continued to lose weight, became cachetic and debilitated and, on Jan 1, 1945, died

Abstract of Necropsy Protocol—Gross Findings Lungs The right pleural cavity contained 2,000 cc of pale yellow fluid flecked with fibrin The lower lobe of the right lung was atelectatic, while the apex revealed several small cavities from 1 to 5 mm in diameter, forming a honeycombed tissue surrounded by a solid white parenchyma These cavities were lined by a pale gray, granulating membrane No definite miliary or nodular granulomas were seen on gross inspection

The left pleural cavity was almost obliterated by fibrous adhesions The cut surface of the lung did not reveal any gross pathologic changes The tracheobronchial lymph nodes were enlarged up to 1 5 cm The cut section revealed extensive caseous and calcareocaseous destruction

Heart The pericardial sac was completely obliterated by firm, fibrous adhesions except for a linear pocket of thick pus along the left side of the heart Here the visceral and parietal layers were roughened by a thick, organizing, fibrinopurulent exudate which extended up over the base

Alimentary Tract The mesothelial surfaces of the mesentery and of the parietal wall were moderately studded with fine, white, glistening miliary lesions, of pinpoint

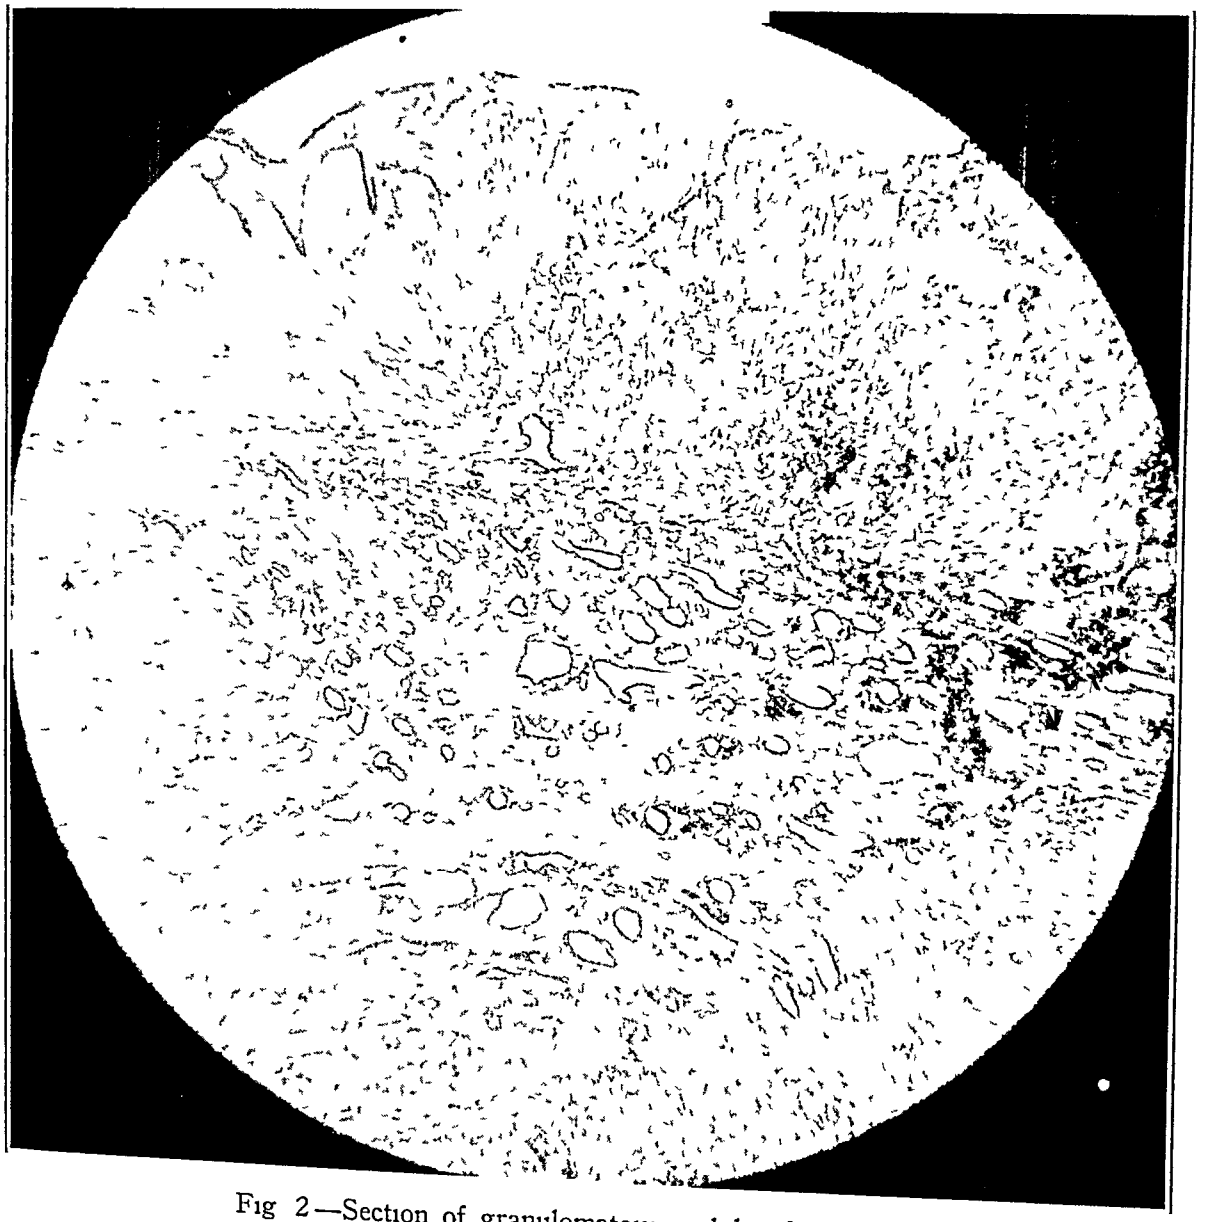

Fig 2—Section of granulomatous nodule of the face

to pinhead size Short fibrous tags were found along the mesenteric attachment and over the leaves of the mesentery

The esophagus was grossly normal except for a longitudinal lesion of 7 by 2 mm located on the anterior wall 7 5 cm below the rima glottidis The stomach had a pale pink and somewhat atrophic mucosa Three small, ulcerated outpouchings of the mucosa were located in the magenstrasse, 4 cm proximal to the pylorus These were about 3 to 4 mm in diameter, with smooth bases and borders The overlying serosa was thickened with fibrous tags The intestines

also contained similar small, shallow, ulcerated areas Their margins were formed by a delicate, pale, granular membrane, the overlying serosa was thickened by fibrous tags A solitary lesion was found in the duodenum, while about twenty-four such lesions were seen in the cecum and ascending colon Most of the lesions were 2 by 4 mm, with their long axes at right angles to the long axis of the bowel

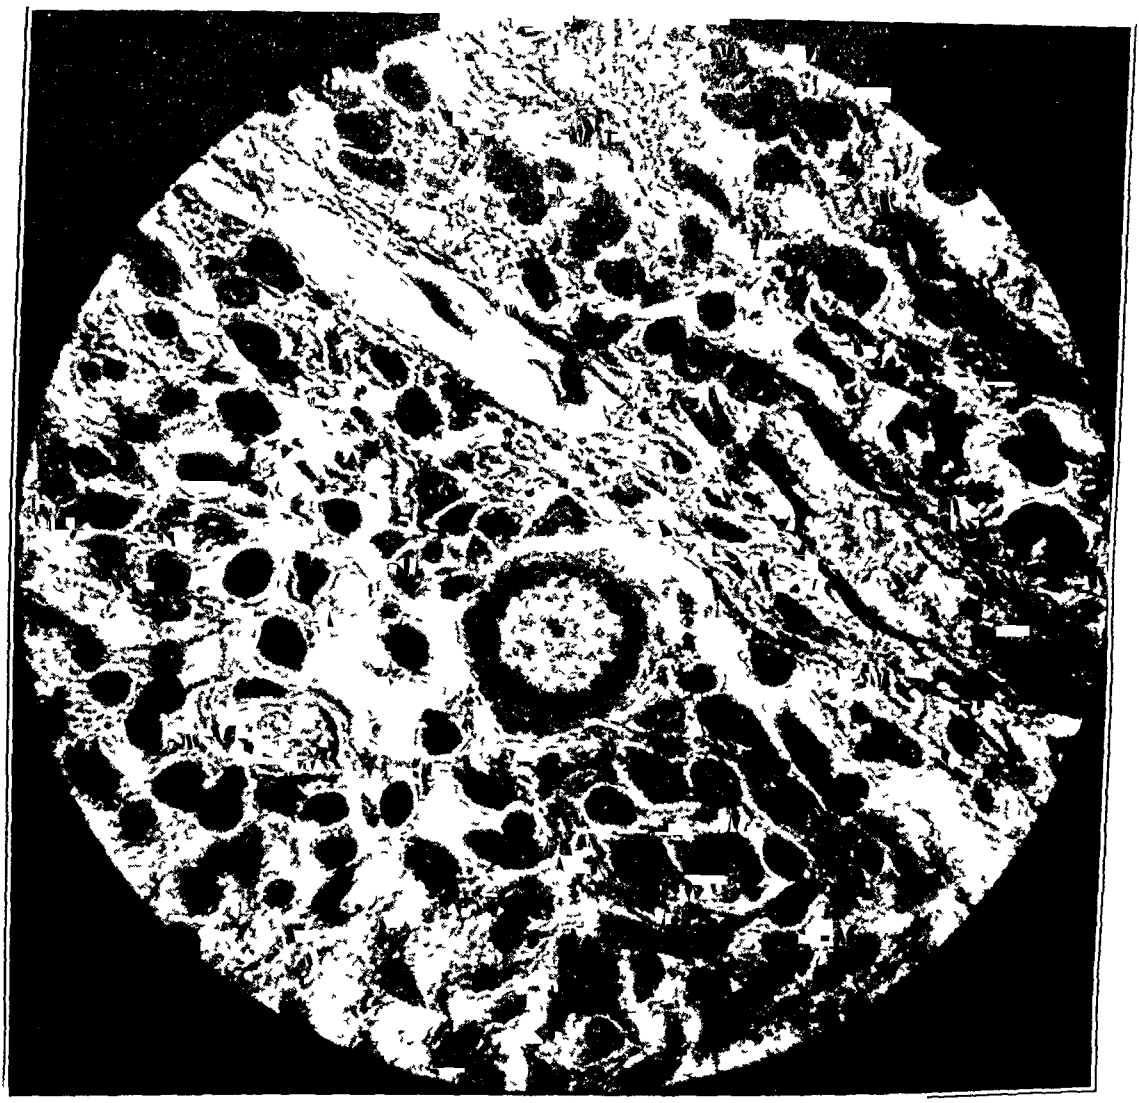

Fig 3—High power view, showing a characteristic mature endosporulating spherule

Osseous System The only significant bone lesion was a small area of osteomyelitis of the left seventh rib The cortex was irregularly thickened for a distance of 7 mm proximal to the medullary lesion on the pleural surface

Microscopic Observations (figs 2 and 3) In general the lesions were typical granulomas with numerous coccidioidal spherules The larger lesions showed tubercle formation, with central caseation The spherules were present free in the proliferating reactive border and within the Langhans giant cells The granulation tissue was composed of capillaries, proliferating endothelial cells and young collagen

connective tissue elements, a heavy infiltration of plasma cells and lymphocytes, tissue mast cells, mononuclear phagocytes with cell detritus and an occasional polymorphonuclear leukocyte Varying numbers and sizes of coccidioidal spores were scattered throughout this granulomatous tissue Many contained endospores, but in some instances they were devoid of these and appeared as empty cysts with double-contoured envelopes The cells of the tubercles were arranged in a

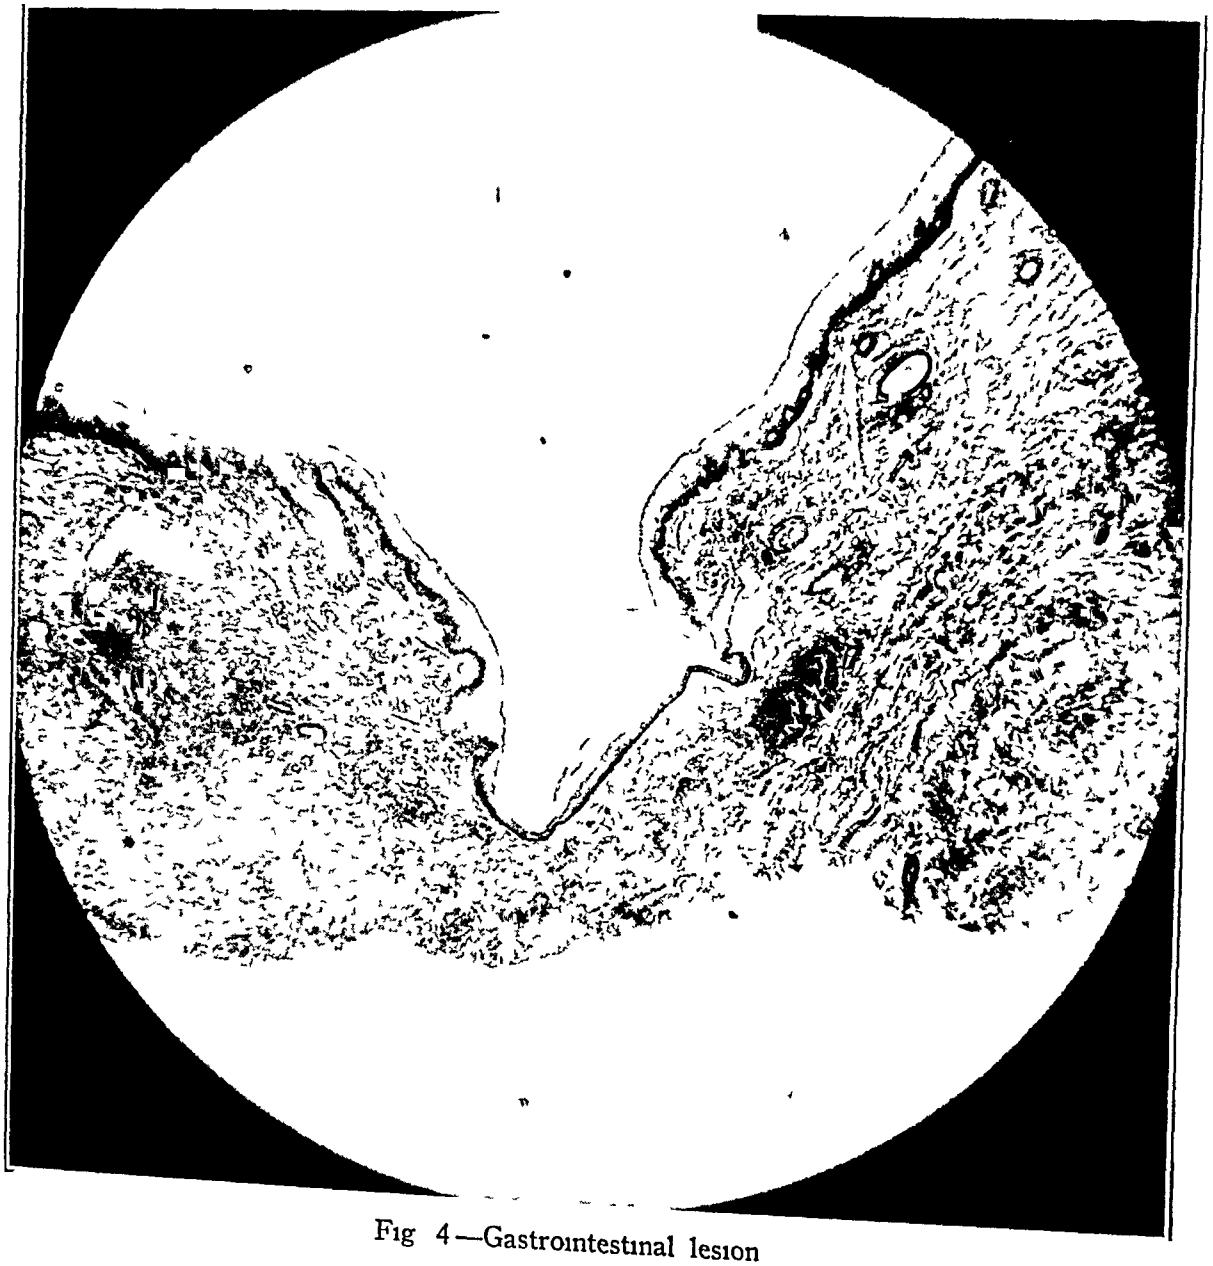

Fig 4—Gastrointestinal lesion

somewhat concentric, onionskin lamination The gastrointestinal lesions (fig 4) showed similar ulcerative granulomatous pathologic changes, involving the mucosa, submucosa and, to a lesser extent, the muscularis

Case 2—E A H, a 20 year old American Negro, was admitted to the surgical service of the United States Naval Hospital, San Diego, Calif, on Jan 26, 1946, complaining of pain in the right upper portion of the abdomen Prior to the completion of comprehensive laboratory examinations he constituted an interesting diagnostic problem, inasmuch as the differential diagnoses listed, among other

things, syphilitic hepatitis, subacute appendicitis, low grade hepatitis with multiple abscesses, parasitic infection of the intestine with perforation, trichinosis, secondary syphilis, nephrolithiasis, Loffler's syndrome, eosinophilic leukemia and pneumonitis

On January 24, epigastric pain, which lasted for about two hours, developed after meals On January 25, the patient had pain in the lower right anterior portion of the chest, but no dyspnea or infection of the upper respiratory tract, and afterward a persistent dull, aching pain appeared on the right side at the costal margin The following day, the patient first noticed two small papules, one on the midback and one over the epigastrium

The physical examination showed essentially normal conditions except for moderate tenderness in the right upper quadrant at the costal margin The abdomen was soft, and no masses or organs were palpable The chest appeared clear on auscultation and percussion Over the midepigastrium and midback there were two small, suppurating nodules

Fig 5 (case 2) —Showing lesions of lips and chin from which Coccidioides immitis was isolated

The erythrocyte sedimentation rate was 18 mm per hour, and the white cell count was 11,250, with 24 per cent eosinophils Subsequent blood counts all revealed an eosinophil count averaging about 14 per cent Repeated coccidioidin skin tests had negative reactions Reactions to the Kahn and Kline tests were initially positive, but to the Kolmer, Wassermann and repeated Kahn tests they were negative Biopsy of the nodule over the upper portion of the abdomen revealed numerous double-contoured, highly refractive spores characteristic of Coccidioides immitis Roentgenograms of the chest showed increased mottled markings of the central and lower central lung fields

The patient was put on a supportive regimen but continued to have a low grade fever He acquired new cutaneous lesions (fig 5) similar to the original two and rapidly began to fail as the pulmonary infection progressed C immitis was isolated from the purulent discharge of the ulcerating lesions He was given whole blood transfusions, 100 cc of protein hydrolysates (parenamine®) daily and 15 drops of

a saturated solution of potassium iodide three times daily On March 26, he was started on a course of penicillin, receiving 50,000 units every two hours for a total of 3,600,000 units His downward course progressed, and on April 2, just after completion of the course of penicillin, he began to exhibit signs and symptoms of cerebral involvement, which terminated in meningitis Spinal puncture revealed a grossly clear fluid which, on microscopic examination and later on culture, revealed C immitis On April 7, the patient died Postmortem examination revealed miliary coccidioidomycosis of the meninges, lungs, spleen and lymph nodes and a large granuloma of the sternum and the right second rib anteriorly There were many extradural abscesses The microscopic examination of all the tissues involved confirmed the gross findings, revealing typical lesions packed with C immitis

SYMPTOMATOLOGY AND CLINICAL COURSE

The infection assumes a wide variety of manifestations, ranging from the asymptomatic variety to the frequently fatal disseminated form, and can be best understood and discussed under the following classification proposed by Smith [6] Clinically it may be divided into three forms primary, intermediate and progressive

Primary Stage—In the majority of cases in the endemic areas, the onset of the initial infection may pass unrecognized or be interpreted as a mild infection of the respiratory tract This was probably the situation in 1 of our cases (case 2), in which the patient gave a history of an infection of the respiratory tract two months prior to his admission to the hospital On the other hand, the respiratory symptoms may be prostrating and more prolonged, accompanied by malaise, substernal pain in the chest, cough, night sweats and nasopharyngitis A small percentage of patients suffer a recurrence of fever in from three days to three weeks, associated with erythema nodosum or erythema multiforme, regarded as an expression of the allergic state While the disease in this stage is usually self limited, it must be remembered that a very small undetermined percentage may steadily progress to the disseminated form

Intermediate Stage—With a few exceptions the pathologic changes and symptoms in this stage are strikingly like those found in tuberculosis The findings may vary from the mildest to massive consolidation, cavity formation or scattered lesions resembling miliary tuberculosis, and the course may likewise vary in direct relation to the severity of the involvement Although cavity formation may occur without subjective symptoms, most patients complain of pleuritic pain and a productive cough Unlike the situation with tuberculosis, even patients with the most extensive pulmonary involvement recover, and the symptoms in relation to the amount of involvement are less severe than in tuberculosis Treatment is entirely symptomatic, with the elevation of the sedimentation rate the best guide for clinical management

Progressive or Disseminated Form—Fortunately the incidence of this form of the disease, which carries a very high mortality, is very low The incidence is definitely higher in the heavily pigmented races, of which both patients whose cases form the basis of this report were members The symptoms and the course vary with the organs involved, and the disease may terminate in death in a period of from a few weeks to a year In 1 of our cases the disease was more fulminating in type, terminating with meningitis in about two and one-half months, while in the other the patient lingered on for nine months Involvement of the bones, joints,

6 Smith, C E Coccidioidomycosis, M Clin North America **27** 790 (May) 1943

lungs, mediastinum and lymph glands is common, with the frequent development of verrucous and granulomatous nodules of the skin and subcutaneous cold abscesses The development of meningitis is evidence of wide dissemination and may occur with or without extensive visceral involvement The course of the meningitis is not unlike that of tuberculous meningitis, and, coincident with mental confusion in 1 of our cases, spherules of C immitis were demonstrated in the spinal fluid Gastrointestinal involvement is said not to occur because of digestion of the spherules, but Greaves [7] reported lesions in the small intestine and Ruddock [8] made the diagnosis by peritoneoscopy in a patient thought to have tuberculous peritonitis One of our patients (case 1) presented multiple lesions of the gastrointestinal tract, extending from the esophagus to the transverse colon They consisted of small, ulcerated outpouchings of the mucosa, 3 to 4 mm in diameter, with smooth bases and borders The margins of the ulcers were formed by a delicate, pale, granular membrane, the overlying serosa was thickened by fibrous tags The long axis of most of the lesions was at right angles to the long axis of the bowel

Treatment.—We are not concerned with the treatment of primary or intermediate coccidioidomycosis in this paper Suffice it to say that bed rest and symptomatic therapy will eventuate ultimately in clinical recovery, except in those cases with extensive cavitation, in which pneumothorax is required It is the progressive variety, of which the cases herewith presented are examples, that have so far been unaffected by a wide choice of remedies The drugs which have been of some value in other deep-seated mycoses, such as thymol, iodides, copper and antimony compounds and potassium tartrate, have uniformly failed to influence the course of the disease Penicillin offered nothing in our hands and has been reported by others [9] as ineffective Great hopes have been entertained for vaccines, but both the use of a stock and autogenous vaccine over a long period of time in increasing doses has been of no avail In order to rid the patient of large reservoirs of organisms which would otherwise be disseminated, all accessible granulomatous nodules were removed Roentgen therapy has been of no benefit, except to flatten exuberant granulomas The outlook in the progressive form of the disease must still be regarded as hopeless

EPIDEMIOLOGY

The epidemiology of coccidioidomycosis has become increasingly important because of the large numbers of men from all parts of the country brought into the endemic areas for training purposes during the past war and because of definite evidence of spread of the endemic areas For a long time after its first recognition, cases were reported only in those living in or near the great central valley of California It was not until 1920 that the first case east of the Mississippi was reported, and in the next decade there were accounts of sporadic cases in the Middle West and the eastern states A recent study by Smith [6] now reveals endemic areas occupying the great central valley of California and extending into southern California, all of Arizona, southern Nevada and southern Utah, probably parts of Idaho, all of New Mexico, western Texas and at least northern Mexico

9 Michael, P , McLaughlin, R F, and Cenac, P L Coccidioidomycosis Report of Unsuccessful Treatment with Penicillin, U S Nav M Bull **43** 122 (July) 1944

One of our patients was born and remained in San Diego county until his entry in the Navy, while the other was born in North Carolina, his only possible contact with the organism coming while he was stationed in San Diego Lee's [10] experience with certain bodies of troops indicates a high percentage of infections when men are exposed to very dusty conditions in an endemic area The recent drought in California poses an additional hazard in the spread of the infection It has also been shown that animals in endemic areas harbor the infection, and the possibility of a rodent reservoir has been advanced Since the infection is carried in dust, the possibility of dissemination in vehicles and luggage of those traveling in and out of the endemic areas cannot be entirely discounted Although the danger on the present evidence is very slight, it is not yet definitely known whether or not the many thousands who were infected during their training period in an endemic area may have serious complications later in life

SUMMARY AND COMMENT

Much has been added to the knowledge and understanding of coccidioidomycosis in the past decade The endemic areas have been redefined and are known to extend over the southwestern United States and northern Mexico The patients in our cases undoubtedly contracted their infections in San Diego county, which had not been considered an endemic area They were both from dark-skinned races, in whom the progressive disseminated, frequently fatal form is most likely to develop Lesions of the gastrointestinal tract, which are said not to occur but have been recorded in the literature on one other occasion, were found widely distributed in 1 of our cases Although the infection in most instances is entirely benign and complete clinical recovery can be anticipated in even those who have pulmonary involvement with cavitation, possible serious complications may develop in later life in some of the many persons who were infected during their training period in an endemic area during the last war The similarity to and distinction from tuberculosis of this disease will become increasingly important to physicians everywhere, since these men have now returned to their homes throughout the United States Specific treatment is still lacking, and neither drugs nor vaccines have appreciably altered the course of the progressive disseminated form

REACTIONS IN TATTOOS (CHRONIC DISCOID LUPUS ERYTHEMATOSUS)

JOHN F MADDEN, M D
ST PAUL

Reactions in tattoos generally fall into one of four groups The reactions in one group consist in the immediate response of the skin to the physical injury of tattooing This is rarely accompanied with or followed by secondary infection In

From the Department of Dermatology, Ancker Hospital, St Paul, Dr John F Madden, Director, and the Division of Dermatology and Syphilology, University of Minnesota Medical School, Dr H E Michelson, Director, Minneapolis

rare instances keloid,[1] melanoma,[2] severe pyogenic infection,[3] amputation,[3] gangrene [3] and even death [3] have been reported as direct consequences of tattooing

Allergic reactions to the material used in tattooing can occur immediately or at any time during the existence of the tattoo Allergic reactions to mercury, usually used in the red part of tattoos, have been most frequently noted [4] The allergic dermatitis may either be confined to the tattoo or be generalized The allergenic mercurial compound causing the dermatitis need not be the mercuric sulfide (cinnabar) in the tattoo, but it can be any form of mercury which is used on the skin or internally

Local or systemic disease can be injected into the skin at the time of the operation The manifestations of the injected disease may appear at once or later, the time depending on the particular characteristics of the disease Leprosy,[5] tuberculosis,[6] syphilis,[7] tetanus,[4f] erysipelas [8] and chancroid [8] are reported to have been contracted in this manner

Fig 1—Lesions of chronic discoid lupus erythematosus on the face

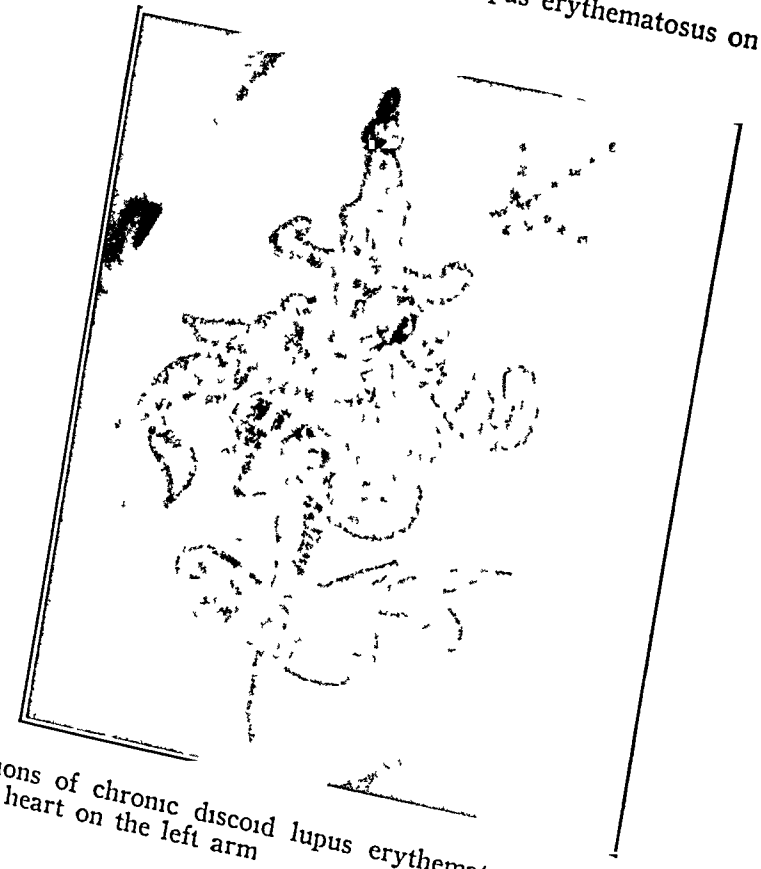

Fig 2—Lesions of chronic discoid lupus erythematosus in the upper half of the tattooed red heart on the left arm

The last group of reactions includes the appearance of local or systemic disease in tattoos after the tattoos have become a site of lowered resistance Brose [9] demonstrated that all portions of tattoos are more sensitive to blows, rubbing and external mechanical stimuli than is normal skin Belote [10] and others showed that tattoos alter the distribution of secondary syphilis The lesions were accentuated in and around tattoos except in the red (mercuric sulfide) portion, where the protective influence of the mercuric ion was greater than the effect of the foreign pigment in lowering the resistance of the area This paper records the first case known to me of chronic discoid lupus erythematosus occurring in a tattoo

Fig 3—Low power view of microscopic section taken from a lesion in the tattoo, showing histopathologic features in keeping with chronic discoid lupus erythematosus

REPORT OF A CASE

J C, aged 36, a white male truck driver, was tattooed on the lateral surface of the left arm in 1943 The tattoo healed after the initial reaction and showed no signs of irritation until November 1947 Then the red part of the tattoo began to itch and burn A dermatitis appeared in the red part of the tattoo in about a week. The patient stated that there was not any known cause for the symptoms

9 Brose Neue Tätowierungsphänomene, Dermat Wchnschr **84** 461-463 (April 2) 1927

10 Belote, G H Tattoo and Syphilis, Arch Dermat & Syph **18** 200-209 (Aug) 1928

or the eruption This development was accompanied by a similar dermatitis on the face, which also itched and burned In March 1948 the patient had scattered, pea-sized to dime-sized, dry, round, erythematous, pruritic papules covered with an adherent carpet-tack-like scale on the face and in the red part of the tattoo There were about fifteen lesions on the face and four in the tattoo Reactions in the Mantoux test and in serologic tests for syphilis were negative A roentgenogram of the chest and other laboratory studies showed normal conditions Biopsy specimens from lesions on the face and from the tattoo showed histopathologic features which were in keeping with the diagnosis of chronic discoid lupus erythematosus All lesions seemed to respond to bismuth subsalicylate in oil given intramuscularly On two separate occasions the eruption showed an acute flare-up when the face was exposed to sun and wind for about three hours All lesions flared, even though those in the tattoo were protected by a shirt and a heavy leather jacket

SUMMARY

A case of chronic discoid lupus erythematosus with characteristic lesions on the face and in the red portion of a tattoo on the left arm is reported Wind burn and sunburn caused the eruption to flare simultaneously on the face and arm even though the eruption on the arm was protected by a shirt and heavy leather jacket

IDENTICAL ALOPECIA AREATA IN IDENTICAL TWINS

OWEN S HENDREN, M D
BIRMINGHAM, MICH

In the past many dermatologic and nondermatologic diseases have been reported in twins To enumerate only a few, they are lichen planus,[1] von Recklinghausen's disease (neurofibromatosis),[2] rosacea,[3] summer prurigo,[4] ichthyosis hystrix,[5] peptic ulcers,[6] calcified mesenteric glands,[7] pilonidal cysts,[8] ephelides,[9]

(Footnotes continued on next page)

lentigines,[9] and dermatitis herpetiformis.[9] There have also been reported several cases of allergy of similar type and onset.[10]

The following case of alopecia areata beginning at the same time on identical areas of the scalp in monozygotic twins aroused our interest.

REPORT OF A CASE

Robert L. and Raymond L., 11 years of age, presented themselves to the Dermatology Clinic, City of Detroit Receiving Hospital, on Oct. 31, 1947, with the complaint that each had a bald spot on his head. Their mother stated that

Showing similarity in appearance of the twins and small areas of alopecia areata in identical locations on the right side of the occiput.

these spots had been first seen by her on the same day in June 1947, that to the best of her knowledge both had appeared at the same time and that she was sure that they had not been present the previous week.

10. Criep, L. H.: Allergy in Identical Twins: Report of Seven Pairs of Twins, J. Allergy **13**: 591 (Sept.) 1942.

The family consisted of the mother, the father and 4 children No other member of the family had or ever had had a similar type of loss of hair Both patients had had measles and pertussis at 18 months of age Robert had had chickenpox when he was 6 years old, but Raymond had not There was no history of other previous illnesses

On examination the boys were strikingly similar in appearance, with the same shade of hair and with the same characteristics in regard to ears, teeth, nose and mouth In all zones of the iris of both patients there was the same type of pigmentation and distribution[11] Both boys exhibited a small area of typical alopecia areata in identical locations on the right side of the occiput approximately 2 by 0 75 cm Below each lesion there were three smaller areas of thinning of the hair but no complete loss in any place except those previously mentioned

Repeated examinations of the scalp under the Wood light revealed no fluorescence in the case of either boy Repeated cultures were negative for tinea capitis The hair appeared normal on direct microscopic examination Observations in blood counts (red cells, white cells and differential), as well as in urinalysis and serologic examinations, were all essentially normal

COMMENT

In a review of the literature for the past several years only 1 case of alopecia areata in twins was found,[12] and that case was somewhat different from the one here presented in that the lesions were not identical and did not appear simultaneously

Several theories have been advanced as to the cause of alopecia areata, but the exact etiology is unknown No single theory will account for all cases of the condition

In presenting this interesting and rather unusual case no attempt is being made to interpret the findings, and it is not our intention to try to prove or disprove any of the theories that have been advocated to date Rather, the case is presented purely as a dermatologic curiosity

SUMMER PRURIGO

Report of a Case Controlled by Diphenhydramine (Benadryl®) Hydrochloride

HARRY W WOOLHANDLER, M D
PITTSBURGH

Summer prurigo is at best an incompletely understood entity While it is generally accepted that hypersensitivity to sunlight produces the eruption, the exact wavelength responsible has never been definitely established Experimental

From the Section of Dermatology, University of Pittsburgh School of Medicine

reproduction of this dermatosis has been accomplished with ultraviolet rays, ordinary sunlight, sunlight passed through window glass, yellow and red rays of longer wavelength only and even alpha and gamma rays [1] Attempts at desensitization have generally been unsuccessful, and, except for symptomatic treatment and avoidance of sunlight, no therapeutic measure of merit has been described Thus, the dramatic response to diphenhydramine hydrochloride (benadryl hydrochloride®) in a recently treated patient appears worthy of reporting

REPORT OF CASE

A 5 year old white girl was first seen by me on April 9, 1947, with an eruption of the cheeks and nose of four days' duration History obtained from the mother indicated that the patient had previously had a similar eruption lasting from June 1946 to October 1946, which initially had involved the face and the forearms At that time the patient had been seen by the family physician, who had prescribed daily exposures to sunshine After a few days of such exposures the eruption spread to the arms, legs and chest, with the lesions becoming moist and crusted for the first time There was no response to local applications, but in early October the eruption healed spontaneously The child's skin then remained entirely clear until April 5, 1947, when the eruption reappeared

Examination on April 9 revealed an eruption involving the cheeks and the nose and consisting of grayish red plaques, which on closer inspection were seen to be made up of closely set papules with adherent scales The lesions on the nose were entirely discrete, while those on the cheeks had coalesced into small plaques A diagnosis of summer prurigo was made, and on April 17 the patient was presented before the Pittsburgh Dermatologic Society, where this diagnosis was accepted by all except one member, who stated the belief that the disease was a dry staphylococcic infection

On April 9, the date of the first visit, the patient's mother was admonished to keep her out of direct sunlight, and a paste containing 3 per cent ichthammol (ichthyol®) was prescribed However, the mother permitted the child out in the sunlight as usual, and three days later the eruption had spread to the forehead and forearms, the original areas of involvement on the cheeks and nose having become more extensive A bland paste containing menthol, phenol, boric acid, zinc oxide, petrolatum and rose water ointment was substituted for the ichthammol paste and elixir benadryl hydrochloride® (a preparation containing 0 25 Gm diphenhydramine hydrochloride [benadryl hydrochloride®] in an elixir containing alcohol, glycerin and water, with sugar, flavoring oils and added color, in each 100 cc) 1 fluidrachm (3 7 cc) three times daily, was prescribed On April 17 the eruption showed no appreciable change, but on April 24 there was striking improvement, the face being almost entirely clear and the eruption on the forearms improved When the patient was next seen, on May 8, the skin of the face was entirely normal and the eruption of the forearms was barely discernible On June 7 no evidence of the original eruption could be seen, but a small area of involvement was found in the sternal region The child's mother admitted having permitted the girl out in the sun during a recent hot spell with no clothing except bathing trunks A promise was then exacted that the child would at no time be permitted outside with less clothing than a dress The sternal involvement

1 Becker, S W, and Obermayer, M E Modern Dermatology and Syphilology, ed 2, Philadelphia, J B Lippincott Company, 1947, p 291

healed in a few days, and no further relapses occurred during the entire summer Use of diphenhydramine hydrochloride was stopped on October 15, and there was no recurrence of the eruption up to Feb 15, 1948

COMMENT

An attempt was made during the management of this case to obtain consent to temporary discontinue use of the diphenhydramine hydrochloride (benadryl hydrochloride®), in order more definitely to establish the role of this drug in treatment of summer prurigo The mother's refusal prevented this or any other experiments from being carried out Nevertheless, I feel that the evidence, while presumptive, indicates that diphenhydramine hydrochloride was responsible for the control of this eruption At no time was any other medicament, except the bland paste mentioned, employed and the child was apparently exposed to direct sunlight regularly during the entire spring and summer That the diagnosis was probably accurate is attested to by the almost unanimous agreement of more than twenty dermatologists Further use of this drug in treatment of summer prurigo is definitely indicated, similar results would, of course, suggest that histamine plays a role in the causation of summer prurigo

SOLID CARBON DIOXIDE AS AN ANESTHETIC IN ELECTRODESICCATION OF CUTANEOUS BLEMISHES

ALEXANDER BREGMAN, M D
Associate Dermatologist, Englewood Hospital, Englewood, N J
EDGEWATER, N J

The electrodesiccation of cutaneous blemishes necessitates the use of local anesthesia because without it the procedure is too painful to be acceptable to patients Of the two methods of producing local anesthesia, namely, ethyl chloride freezing spray and infiltration with procaine or similar drugs, the local infiltration anesthesia is the more practicable Ethyl chloride spray is impracticable for two reasons It is inflammable, and thus unsafe for use in the presence of a spark, and the anesthetic effect wears off by the time the ethyl chloride has evaporated In using electrodesiccation for such lesions as pigmented moles or common warts in the region of the cartilaginous portion of the nose it is sometimes difficult for one to employ an anesthetic acting by local infiltration because of the close proximity of the underlying cartilage and lack of loose subcutaneous tissue which would allow infiltration with the anesthetic

Solid carbon dioxide used for its anesthetic effects works well in such situations It possesses the advantages of other types of compounds producing local anesthesia without exhibiting their drawbacks, and is less objectionable to the patient It is not inflammable, and it is of more lasting effect than is ethyl chloride spray, the latter characteristic being accounted for by the fact that ethyl chloride produces a temperature of about —31 F, whereas with solid carbon dioxide a temperature as low as — 110 F can be obtained

Although any type of machine for making solid carbon dioxide can be used satisfactorily for this purpose, I employ the Kidde dry ice® apparatus The whole

procedure of producing anesthesia by freezing does not take more than a couple of minutes I apply the solid carbon dioxide pencil for ten seconds with moderate pressure and then proceed with electrodesiccation

After having used this method on a few patients with lesions in the nasal region and having proved to my complete satisfaction its feasibility and practicability I began to employ it in producing anesthesia on other parts of the body whenever electrodesiccation was indicated—in treating small isolated lesions of various natures I submit this method in the expectation that others may try it to determine the possibilities of this simple and practical way of treating cutaneous blemishes

ALLERGY TO WAX CRAYONS

Report of a Case

MIRIAM LUTEN, M D
PORTLAND, ORE

In 1947, two reports of cases of poisoning by wax crayons appeared in the literature The first one, by Jones and Brieger,[1] described a child in whom symptoms of severe paranitraniline poisoning developed as a result of the patient's eating red and orange crayons In the second report, Clark [2] told of the case of a child who acquired methemoglobinemia from eating yellow and orange crayons Schwartz, Tulipan and Peck [3] stated that school teachers may acquire dermatitis of the terminal ends of the thumb and index fingers from the dye in colored crayons They found that among 81 workers in refineries manufacturing paraffin 19 had boils or acne on their arms and hands They found that oil and wax acne differs from acne vulgaris in that the eruption in oil and wax acne is oftener found on the body and legs than on the face, which situation they attributed to the plugging of the orifices of the hair and the sebaceous follicles, with formation of comedos which become secondarily infected They expressed the opinion that the percentage of wax warts, acne and pustules decreases in direct proportion to the purity of the paraffin handled and that workers handling the white, refined product are almost free from these conditions

REPORT OF CASE

S S D, a 7 year old girl, came to the office, complaining of sties which had been present almost continuously for four years For the previous two years she had had severe itching of the axillas and the buttocks, followed by many furuncles in these regions Treatment had consisted of stock and autogenous vaccines, stannoxyl® (a preparation containing 42 5 per cent metallic tin and 7 5 per cent tin oxide) and general hygienic measures, all without benefit There were no refractive errors

1 Jones, J A, and Brieger, H Poisoning Due to Ingestion of Wax Crayons Report of a Case, J Pediat **30** 422 (April) 1947

2 Clark, E R Poisoning Due to Ingestion of Wax Crayons Report of a Case, J A M A **135** 917 (Dec 6) 1947

3 Schwartz, L, Tulipan L, and Peck, S M Occupational Diseases of the Skin, ed 2, Philadelphia, Lea & Febiger, 1947, pp 240, 243 and 858

After the suggestion that this condition could be due to allergy, the mother could recall only one material that the child had used continuously during this time At 3 years of age, she had started playing with wax crayons every day Patch tests of wax crayons and fatty extracts of house dust and dog hair made on the skin around the axillas were indeterminate When crayons were taken away from the child, she was free from sties and boils for two and one half weeks, the longest period in the past four years She was given a crayon for two minutes Within one-half hour, her eyelids became red, and sties appeared on the lids by the next morning Perma® crayons, which the manufacturer stated are made by an entirely different process from that used in making the crayola,® produced sties after similar exposure During the succeeding months, infections on the lids followed the child's handling of pictures colored by other children and contact with candles Colored pencils, protected by wood covers, were tolerated for a short time only

Four trials were made with a piece of wax without dye, which was furnished by the manufacturer After one of these trials, a small sty appeared Smears made from the draining pustules contained diplococci The last trial with both uncolored and colored wax, one year later, caused only a generalized pruritus but no sties

The only local therapy used was tyrothrycin, which the mother believed shortened the duration of the lesions

Throughout the summer months, when the child was not in school or exposed to wax crayons, she remained free from cutaneous lesions, except for one episode in which a severe edema of the eyelids followed playing in weeds This edema disappeared almost at once when the child's face was washed Scratch tests at this time showed strong reactions to the pollen of English plantain

SUMMARY

A case is reported in which sties, furuncles and pruritus repeatedly followed exposure to wax crayons

Lymphoblastoma, Tumors on the Forehead and Postauricular Subcutaneous Nodules Presented by DR MAX B KAMPF

Granuloma Annulare of the Legs with Keratotic Lesions Presented by DR LOUIS CHARGIN

Purpura Annularis Telangiectodes? Radiodermatitis? Hemostasis Dermatitis? Presented by DR PAUL GROSS

E B, a white woman aged 54, has had recurrent ulcerations on the feet for the past ten years In 1940 she was admitted to the Hospital for Joint Diseases because of multiple ulcers After the ulcers had healed many atrophic areas were found on the skin of both feet On the periphery of the atrophic patches were many bright red purpuric papules and telangiectases The diagnosis of purpura Majocchi was considered at the time, but the patient did not return for further treatment In October 1946 she was again hospitalized At that time large ulcers were present below the external and internal malleoli and on the dorsum of the right big toe Small ulcerations were also present on the dorsal and lateral surfaces of several toes of the left foot In addition, she had a seborrheic dermatitis of the nasolabial folds and eyebrows

The prothrombin time was increased to 30 seconds, and there was secondary anemia On October 16 the sedimentation rate was 70 mm in 45 minutes, on October 28, 45 mm and on, November 7, 15 mm The cholesterol content of the blood was 319 mg per hundred cubic centimeters, of which 30 per cent was free cholesterol and 70 per cent esterified cholesterol The thrombocyte count was normal The result of a tourniquet test for capillary fragility was positive The result of the Peck test with moccasin venom was positive on the forearm, thigh and the affected area

Treatment consisted of complete bed rest, applications of wet dressings with acriflavine and later of nitrofurazone ointment The patient was given ascorbic acid, 500 mg a day, vitamin B complex, folic acid, ferrous sulfate, and menadione The ulcers healed rapidly, and the patient was permitted to leave the bed for about an hour a day After two days of this regimen there developed purpuric macules and dark red puncta around the atrophic scars Some of these lesions changed into small necrotic ulcers the size of a pinhead

Since Dec 26, 1946, the patient has been receiving biweekly injections of moccasin snake venom No purpuric lesions have appeared recently, but there developed a small ulcer at the base of the left big toe

DISCUSSION

DR CHARLES WOLF I could not see any clinical manifestations of Majocchi's disease There is, however, a vasocirculatory disturbance present which produced sclerosis of the peripheral vessels I think that the pulsation in the dorsalis pedis is, if not entirely obliterated, at least decreased The atrophic changes are due to the sclerosis of the peripheral blood vessels

DR DAVID BLOOM Clinically the eruption resembles radiodermatitis No other diagnosis can be made from the appearance of the lesions tonight

DR MAX JESSNER I would be more inclined to regard this case as one of radiodermatitis, especially in view of the fact that ten roentgen ray treatments had been given to the area Moreover, the lesions suggest healed ulcers, perhaps with superimposed radiodermatitis The patient also presents a peculiar thickening of the skin of both knees, with yellowish discoloration, not unlike housewife's knee, which I do not remember ever having seen previously However, the usual keratosis in housewive's knee is missing here

DR LOUIS CHARGIN I agree with those who are of the opinion that this is not Majocchi's disease In Majocchi's disease the lesions are much smaller, situated higher up on the legs, usually there is some atrophy in the center, and the lesions are annular I cannot classify this process, but these scleroderma-like changes are not infrequently seen in elderly persons, particularly women

DR ERNST NATHAN The patient presents atrophic patches on the knees and on the legs, linear stripes along the tibias and scleroderma-like changes, all of which impressed me as acrodermatitis chronica atrophicans with scleroderma-like changes

DR WILBERT SACHS I do not consider radiodermatitis or scleroderma in this case Clinically, Majocchi's disease must be distinguished from Schamberg's disease and similar processes However, since Majocchi's presents a definite histologic picture, a biopsy would settle the diagnosis

DR PAUL GROSS As Dr Wolf stated, the cutaneous condition of this patient can be explained only by a vascular disturbance which leads to sclerosis of the peripheral blood vessels and atrophy of the skin The pathologic process accounts for the clinical manifestations consisting of telangiectasis, purpura, necrosis and atrophy This could be clearly followed by prolonged observation of the patient while she was in the hospital

The unusual feature of this case was the extensive ulceration which developed on the dorsa of the feet Because of this, it was difficult to consider the diagnosis of Majocchi's purpura unless there was something in the pathologic changes of the disease which could explain the atypical manifestations Actually necrosis has been described as part of the histologic picture of purpura annularis Apparently the severity of the vascular damage in this case produced sufficient necrosis to lead to ulceration Secondary infection may have been an added feature and has aggravated the formation of ulcers The improvement of the circulation by treatment with bed rest and antiseptic ointment brought about healing of the ulcers in a relatively short time If the ulcerations had been the result of a chronic radiodermatitis, the patient would have experienced severe pain, and healing would not have been prompt Prior to the patient's admission to the hospital, the case had been managed as a case of radiodermatitis without benefit

Dermatitis Herpetiformis Arsenical Keratoses and Pigmentation. Ulcer of the Leg Presented by DR ALEXANDER A FISHER

Senile Elastosis of the Neck (Pseudo Xanthoma Elasticum?) Presented by DR PAUL GROSS

A Case for Diagnosis (Necrobiosis Lipoidica? Tuberculoderm?) Presented by DR MORRIS LEIDER and (by invitation) CAPT CHARLES D BELL

Ragweed Dermatitis Presented by DR ALEXANDER A FISHER

P B, a man aged 64, was in good health and free from any cutaneous disease until September 1936, when he walked barefoot through some lots in Astoria, N Y A vesicular eruption appeared on the back of the feet and legs It was diagnosed as dermatitis due to poison ivy and persisted for five months

The eruption recurred in September 1937, affecting mildly the feet, legs, face, hands, forearms and scrotum It then became perennial, with exacerbations from September to May The most comfortable months were June and July

At present there are thickened lichenified lesions on the face and forearms On the face the eruption is sharply limited to the upper part of the forehead

Patch tests with the following oleoresins gave positive reactions short ragweed, cocklebur, sheep sorrel, Kentucky blue grass, red top, short poison ivy, orchard grass and timothy Patch tests with protein extracts of trees, grasses and weeds showed a positive reaction only to oak Results of scratch tests with these protein extracts were negative The result of a patch test with a 5 per cent glycerine solution of ragweed oil (Hollister-Steer) was negative The patient has received oral treatment with oleoresins according to the Shelmire method

DISCUSSION

DR RUDOLF L BAER The patient had a positive reaction to the so-called "protein" fraction of the oak pollen I do not know whether there is any evidence that the oak protein has been of clinical significance Among the extracts available for testing, the "protein" fraction of oak pollen was included Unfortunately, no acetone extract of oak was available, so that it is impossible to state whether this patient is also sensitive to the oil fraction

It is probable that the fractions contained in various extracts differ considerably A patient suffering from a similar eruption at the New York Skin and Cancer Unit was tested with the following ragweed extracts (*a*) the oleoresin, (*b*) the so-called "protein" fraction in a glycerinated extract and (*c*) the so-called "protein" fraction in a powdered extract This patient reacted to the oleoresin fraction and to the powdered "protein" extract but not to the glycerinated extract, which is supposed to contain the same fraction as the powdered extract This indicates that there is a great difference between preparations which, it is assumed, contain the same fraction

DR CHARLES WOLF The history indicates that this patient was exposed to various flowers and pollens a long time ago, but not recently Still he exhibits a fairly pronounced eruption on the face and forearms, although he has not been in contact with these suspected allergens How can one explain the fact that the dermatitis still persists? Is it possible that this patient's sensitivity is polyvalent and reacts to many agents? What is the therapeutic approach to this problem?

DR MARION B SULZBERGER In the preparation of plant extracts with the usual variety of solvents, one extracts a great number of different substances in each of the fractions Dr Coca and I have demonstrated that in the case of allergic contact dermatitis to ragweed and to certain other plants it was a fat-solvent soluble fraction which contained the usual allergen This might be misinterpreted The fact is that in most common forms of allergic eczematous contact dermatitis, water-soluble materials, including many dyes, metallic salts and local anesthetics, are responsible

DR ALEXANDER A FISHER This case is puzzling Some are of the opinion that the oil remains in wearing apparel for many months There is also, as Dr Wolf suggests, a possibility that this patient became allergic to pyrethrum, which is related chemically, and that is what causes the eruption to become perennial As Dr Sulzberger pointed out, the aqueous fraction is frequently responsible for the dermatitis The Mitchells have reported a case of the disease due to aqueous fraction of timothy which they were able to cure by injections of the ordinary extract used for hay fever

Angioma Resembling Idiopathic Multiple Hemorrhagic Sarcoma Presented by DR HARRY B FEILER

Wilbert Sachs, M D, *President*

Henry Silver, M D, *Secretary*

March 20, 1947

Erythroplasia (Cured by Application of a Mixture of Neoarsphenamine, Glycerin and Water) Presented by DR WILBERT SACHS and DR PERRY M SACHS

Erythroplasia of Queyrat (No Biopsy) Presented by DR CHARLES PINES

Poikiloderma Vasculare Atrophicans (Jacobi) Presented by DR FRANCES PASCHER

Pityriasis Rubra Pilaris Presented by DR DAVID BLOOM

F C, a woman aged 57, registered at the Skin and Cancer Unit of the New York Post-Graduate Hospital on Feb 14, 1947, complaining of an eruption of five weeks' duration The past and family histories were irrelevant

The patient presents on the face erythematous scaly plaques which toward the neck are associated with spinulous follicular keratotic plugs On the anterior and posterior aspects of the trunk there are irregularly shaped, erythematous scaly patches and groups of keratotic follicular yellowish or skin-colored papules or plugs the size of a pinpoint or pinhead On the extensor surfaces of the forearms and hands, lateral aspects of the arms and thighs, there is a similar eruption The scalp shows diffuse scaling On the forehead and around the eyes there are numerous small fibromatous lesions and skin tags The palms and soles show considerable brownish-yellowish hyperkeratosis

The patient has no subjective complaints and seems to be otherwise in good health

Results of laboratory examinations, including urinalysis, a Wassermann test of the blood and a determination of the vitamin A content of the blood, were normal The blood cell and differential count showed an abnormal low white cell count of 3,500 and relative lymphocytosis (56 per cent lymphocytes) The report of the histologic examination of an erythematous lesion taken from the abdomen was possible early exudative lichenoid discoid dermatosis

DISCUSSION

DR WILBERT SACHS Microscopically there is no evidence of this disease The picture is that of exudative discoid and lichenoid dermatosis Recently Dr Perry Sachs and I reported 3 cases occurring in female patients (*J Invest Dermat* 8 215, 1947)

DR PAUL GROSS I agree with Dr Bloom that this is a case of pityriasis rubra pilaris The patient has leukopenia, it would also be of interest to make a complete hemogram I recommend treatment with crude liver extract and folic acid

DR DAVID BLOOM I presented this case because it is clinically typical, and yet the results of the histologic examination did not confirm the diagnosis It should be noted that when the biopsy specimen is taken from an erythematous plaque in which the keratotic papules have disappeared the pathologist is unable to make a diagnosis of pityriasis rubra pilaris I wish also to mention that a majority of the patients with pityriasis rubra pilaris that I have observed were all in the fifth decade and not young persons as mentioned in dermatologic textbooks

DR PAUL GROSS O'Leary makes a distinction between pityriasis rubra pilaris and pityriasis-rubra-like eruptions I think that this division is justified by the clinical picture, course and response to therapy I cannot agree with Dr Bloom concerning the age groups involved I have seen several children with extensive eruptions, usually with a sudden onset, showing the clinical features of pityriasis rubra pilaris These patients have shown a dramatic response to a combination of vitamin B complex and vitamin A

Early Mycosis Fungoides, Psoriasiform Lesions Presented by DR ADOLPH ROSTENBERG and DR WILLIAM M SISKIND

Idiopathic Onycholysis, Improved with Thyroid and Vitamin A Therapy Presented by DR ALEXANDER A FISHER

V C, aged 16, first noticed about three years previously that the nails became soft and separated from the nail bed

When first seen, on Dec 17, 1945, all finger nails were involved (kodachrome® slide presentation) He had been under the care of another dermatologist for one and one-half years and had received roentgen ray treatment, ultraviolet rays and various ointments without apparent effect

Results of the physical examination were normal except for a pulse rate of 82 A medical consultant stated that at this age basal metabolism readings are not reliable, and the basal metabolic rate was therefore not established The patient was given thyroid, ¼ grain (16 mg) three times a day

When he returned in a week the pulse rate was 92, and he complained of nervousness The dose of thyroid was then reduced to ¼ grain twice daily, and he was given, in addition, vitamin A, 100,000 units daily, to augment the

thyroid therapy For four months there was no change in the nails By June 1946 there was definite improvement, which has been continuous At present all the nails have practically returned to normal

DISCUSSION

DR PAUL GROSS There is a definite relationship between the thyroid and the vitamin A metabolism In cases of hypothyroidism there is frequently a vitamin A deficiency The excellent therapeutic result obtained by Dr Fisher is noteworthy

DR EMANUEL MUSKATBLIT It seems to me that onycholysis is not always of the same origin Some of these cases have an occupational background In others a separation of the nail from its bed results when the patients constantly soak their hands in water In such cases removal of the cause results in a cure

DR HENRY SILVER I consider the point raised by Dr Muskatblit pertinent The role of continuous use of soap and water should not be underestimated, particularly in patients with systemic disturbances The condition in this case, with the manifest thyroid disturbance, may well fall in this group (Silver, H, and Chiego, B Brittleness of Nails, *J Invest Dermat* **3** 5, 1940)

DR ALEXANDER A FISHER In spite of this boy's washing his hands many times a day, he is improving with vitamin A and thyroid therapy Moreover, it is strong alkali which causes onycholysis, and he denies the use of strong soaps

Circumscribed Scleroderma (Treated with Promin®). Presented by DR HARRY B FEILER.

L S, a woman aged 74, has been complaining of pain, burning sensation and tightness of the skin of the chest In May 1946, she noticed a patch about 3 by 1½ inches (8 by 4 cm) in diameter, located on the right side of the chest, which was hard, white and glistening and was surrounded by a violaceous border At present the lesion is still of the same size The blanched area is somewhat softer and has the remnant of the violaceous border Recently a few linear lesions appeared above the involved area

The patient has been given polyvitamins by mouth, and, with this regimen, there was a disappearance of the leathery consistency in the lesion, but otherwise there was no change She has received intramuscular injections of 50,000 units of vitamin A every second day for three weeks without any noticeable improvement

For the past week promin® (sodium p,p'-diaminodiphenylsulfone-N,N'-didextrose sulfonate) jelly has been applied There developed dermatitis at the site of the lesion accompanied with pain and burning sensation Treatment with promin® was discontinued

DISCUSSION

DR DAVID BLOOM Morphea may disappear without treatment Unless the effect is rapid, one cannot prove that promin® is therapeutically useful in morphea

DR ALEXANDER FISHER If no improvement takes place with promin® I would suggest bismuth subsalicylate Dr John A Stokes first mentioned this type of therapy Several patients at the Skin and Cancer Clinic have improved with treatment with bismuth preparations

DR. CHARLES R REIN Dr Carol Wright and Dr Elmer Gross have had excellent results in the treatment of scleroderma with a bismuth preparation (bistrimate®) given orally

Wilbert Sachs, M D, *President*
Henry Silver, M D, *Secretary*
April 17, 1947

Superficial Epitheliomas, Treated with Podophyllin Presented by DR JOHN GARB

M B, a man aged 73, was first seen on July 17, 1946, presenting three cutaneous lesions He had pneumonia in 1916 He has otherwise been in good health

The largest of the three lesions is located on the left lower border of the anterior part of the chest and epigastrium It is roughly round, 3 inches in diameter (7 5 cm) and dry, with a slightly raised border In that circle are several raised, crusted, irregular, dark red to purplish lesions, which are rough to the touch Most of the lesions have cleared with topical remedies and with exposures to ultraviolet rays, leaving a slightly darker but normal-appearing skin This lesion has been present for the past four years On the inner third of the right clavicle there is a similar patch 1 cm in diameter and an oval patch with axes of 7 and 5 cm on the left side of the back There is a scar in the midportion of the back as a result of an operation performed in 1945 for a carbuncle

The routine laboratory tests showed no abnormalities

Sections were taken from specimens of lesions on the front and back of the chest and examined histologically by Dr Charles F Sims The former showed a somewhat irregular epidermis At one point, extending down into the corium on the under surface of the basal margin, was a small mass composed of basal cells The vessels of the upper part of the corium were moderately dilated and surrounded by mild interstitial edema and a nonspecific cellular reaction From the histologic examination the diagnosis was superficial basal cell epithelioma

Microscopic examination of the specimen taken from the lesion of the back showed features of superficial dermatitis

An ointment containing 5 per cent podophyllin prepared with 8 Gm of castor oil and aquaphor® (an oxycholesterol-petrolatum ointment base), enough to make 2 ounces (57 Gm), was applied on January 30 to the lesions of the chest On February 1, the lesions became ulcerated and a soothing ointment was applied On February 18, the rim of the lesion on the frontal part of the chest was still visible but not raised On February 25, the upper part of the patch on the back was still elevated On March 4, an ointment containing 10 per cent, and on March 11 and 13, 20 per cent of podophyllin was applied to a few spots on the frontal part of the chest On March 31, the 10 per cent ointment was applied to a few spots on both lesions On April 10, the lesion on the back appeared healed except for slight roughness The lesion on the front part of the chest was flattened to the level of the surrounding skin surface The border was still visible because of the brownish pigmentation A section was taken from the pigmented border close to the scar of the original section which showed basal cell epithelioma The histologic examination by Dr A M Sala showed atrophy of the epidermis and moderate round cell infiltration of the corium which appeared somewhat edematous There was no histologic evidence of neoplastic tissue

DISCUSSION

DR MARION B SULZBERGER The lesions give the impression of a superficial epithelioma either entirely healed or in the process of healing Whether a recurrence will take place one cannot foretell Several points need be considered

Certain superficial epitheliomas respond quickly to many forms of therapy Mild caustics and other superficial destructive measures may cure most superficial and small basal cell epitheliomas In evaluating any new therapy, one should keep in mind the ease with which nonspecific measures can remove these so-called carcinomas

Podophyllin is a peculiar substance which has some influence on mitosis As Maurice Sullivan, Lester S King and others have pointed out (in Wise, F, and Sulzberger, M B Yearbook of Dermatology and Syphilology, Chicago, The Year Book Publishers, Inc, 1946, p 510), podophyllin, like colchicine, somehow affects the nuclear metabolism and one sees many cases of arrested mitosis, all in the same phase—the metaphase, I believe It is, therefore, possible that podophyllin or podophyllotoxin may have some specific effect on the multiplying cells of the carcinoma and that the results achieved may be more than a mere nonspecific destructive action The action of podophyllin is well worth studying in relation to epithelial growth and deserves a good deal of further careful experimentation

Dr Frank E Cross New methods of therapy that are simple and promising should be encouraged, on condition that they are as good as or better than the older ones Dr Sulzberger just stated that podophyllin seems to have a basic action in that it interferes with mitosis On the other hand, I take exception to his statement of the "simplicity of ordinary epitheliomas" It is true that a treatment of some basal cell epitheliomas is simple, in others, however, radical measures must be resorted to

Dr Wilbert Sachs A biopsy specimen taken from the "healed" area will determine whether any carcinomatous tissue still remains

Dr John Garb The patient had the lesion on the left lower border of the chest and the epigastrium for forty years A biopsy specimen taken from the pigmented margin adjacent to the original histologic section did not show any epitheliomatous change The patient was not presented tonight as cured He will be kept under observation

Dermatitis Due to Gold, Successfully Treated with BAL (2,3-Dimercaptopropanol) on Two Occasions Presented by Dr Marion B Sulzberger

DISCUSSION

Dr Adolph Rostenberg I used BAL in a case of a widespread dermatitis of unknown cause, and the result was excellent It required several weeks of treatment, but after one injection there developed a severe nitritoid reaction, such as is observed after administration of arsphenamine preparations I have never observed it since and wonder whether this reaction occurs commonly

Dr David Bloom Before administration of BAL the cardiovascular status of the patient should be determined A few weeks ago I observed a patient who received BAL for suspected intoxication due to bismuth This patient, who received an excessive dose of BAL, had a severe reaction manifested by a sensation of burning and constriction about the mouth, face and chest The patient appeared rather ill It was later discovered that this patient had myocardial damage

Dr Marion B Sulzberger This patient was presented to demonstrate therapeutically the effectiveness of BAL in dermatitis due to gold One interesting feature in this case is that the BAL therapy has been effective twice The eruption got worse when BAL therapy was discontinued and then rapidly improved with readministration The therapy was stopped for the reasons given by Dr

Bloom There was slight albuminuria and a systolic blood pressure of 180 mm For that reason Dr Jessner thought it wise to discontinue the BAL therapy when the patient had improved

BAL is a powerful drug and one must be careful, particularly in patients with hypertension One good feature is that BAL is rapidly excreted, and the side effects are usually evanescent It is usual for the blood pressure to rise, however, this is variable, and I have often seen the blood pressure fall after BAL injections Because of the effect of BAL on blood pressure Dr Harry Gold of Cornell University expressed the belief that BAL might be valuable in treatment of certain peripheral vascular diseases It is effective also in allergic dermatitis and other conditions produced by certain metals and is often life saving in cases of allergic dermatitis due to mercury and arsenicals I would estimate that only about half of my patients with arsenical dermatitis have shown rapid and unequivocal improvement Theoretically one should expect a favorable response from BAL applied locally However, BAL is a strong cutaneous allergen, hence as a rule one cannot use it as an external application

A Case for Diagnosis (Sarcoid?) Presented by DR MAX BERKOVSKY

A Puerto Rican, aged 60, was admitted to the dermatologic service of the Metropolitan Hospital on March 20, 1947 There appeared on the left thigh a flat, sharply defined lesion the size of a dime, associated with some itching but no pain Similar spots appeared on all four extremities during the next three months The family history revealed that forty years ago the patient was intimately exposed to active tuberculosis in a relative who subsequently died of the disease The patient stated that to his knowledge he never had gonorrhea or syphilis

In 1932 he had an abscess of the left thigh which was opened and drained In 1939 cardiac decompensation developed Digitalis therapy was instituted, and the patient was discharged much improved In the fall of 1946 he was treated at the Harlem Hospital for a cough, and in three months he was discharged as cured He has lost 15 pounds (7 Kg) in the last ten years The only drug that he takes is feen-a-mint® (a laxative containing phenolphthalein) about twice a month

Physical examination reveals a well developed but poorly nourished man The systolic blood pressure is 180 and the diastolic pressure 90 The skin shows many nummular dark brown sharply demarcated flat-topped nodules with some infiltration They are symmetric and not tender and at present involve all four extremities and to some extent the chest and back

The Wassermann, Kahn and Kline reactions of the blood were negative Urinalysis showed no abnormalities Examination of the blood showed 82 per cent hemoglobin, 3,750,000 red blood cells and 12,200 white blood cells, with 40 per cent polymorphonuclear cells, 32 per cent lymphocytes, 15 per cent eosinophils, 11 per cent monocytes and 2 per cent basophils

Roentgenograms of the chest revealed a round shadow the size of a baseball in the region of the left hilus and extending into the anterior mediastinum This was diagnosed as a dermoid cyst, a teratoma or a benign cystic mass Roentgenograms of the hands showed no abnormalities The reaction to the tuberculin test was negative Histologic examination of specimens taken from the left thigh and left arm showed edema and hyalinosis of the papillae with perivascular infiltration of small round cells There was no evidence of tuberculosis The diagnosis from histologic study was chronic dermatitis of unknown cause

Results of examination of the bone marrow obtained by puncture of the sternum were not diagnostic It showed a decreased cellularity (hypoplasia) with good myeloid distribution, moderate eosinophilia and normal megakaryocytes

During the three weeks' stay at the hospital the patient's condition has remained unchanged A consultation was held with the thoracic surgeon concerning the tumor in the left anterior mediastinum A tentative diagnosis of teratoma or echinococcus cyst was made and exploration advised

DISCUSSION

DR DAVID BLOOM This eruption resembles sarcoid as seen in white persons It would be of interest to study the effect of calciferol in this case

DR LOUIS CHARGIN What is the pathologic report in this case?

DR FRANK E CROSS Clinically the lesion in this case is sarcoid, in spite of the lack of confirmation on histologic study It is possible that the biopsy specimens were taken from nonspecific sites Another biopsy specimen should be taken from a characteristic lesion and examined by a dermatopathologist

DR MAX BERKOVSKY Three biopsy specimens were taken and examined by the general pathologist at the Metropolitan Hospital and Dr Hyman at the New York Post-Graduate Hospital At no time could one justify the diagnosis of sarcoid on histologic study The reaction to the tuberculin test (1 10,000) was negatives Roentgenograms of the bones showed no abnormalities Roentgenographic examination of the chest revealed a mass which the surgeon said was a dermoid cyst in the anteriomediastinal space

DR. PAUL GROSS What has been done to rule out tuberculosis?

DR MAX BERKOVSKY No tuberculoid tissue was found on histologic examination There is nothing to warrant a diagnosis of leprosy

NOTE—The mediastinal tumor was removed by operation, and the histologic examination revealed a thymoma Subsequent histologic studies of cutaneous nodules by Dr W Sachs showed characteristic observations of lymphatic leukemia

Reticulum Cell Sarcoma Presented by DR DAVID B BALLIN

M M, a man aged 44, was previously presented before the New York Dermatological Society on Feb 25, 1947, by Dr Fred Wise, with the following note Additional data, such as results of the pathologic study of the left epitrochlear lymph node excised, roentgenogram of the chest, general medical examination, sternal puncture and electroencephalogram will be reported later

The patient is presented to show the rapid regression after 1 skin unit of roentgen rays (450 r) and to report the results of laboratory studies A hemogram taken on February 20 showed 5,160,000 erythrocytes, 1 8 per cent hemoglobin and a color index of 1 05 There were no eosinophils The results of sternal puncture and examination of the lymph node excised from the left epitrochlear region were reported as normal

Examination on April 16 revealed considerable regression in the satellite lesions about five weeks after the biopsy specimen was taken, but there was no diminution in the size of the main growth On April 3 1 skin unit of roentgen rays filtered through 1 mm of aluminum (450 r) was applied to the main lesion and about

2 inches (5 cm) beyond When the patient was seen on April 15 the growth was entirely flattened out, so that it was only slightly elevated above the surrounding skin

Lichen Planus, Lichen Nitidus Presented by DR JOSEPH L MORSE

R S, a boy aged 7 years, was first seen at the Hospital for Joint Diseases with a generalized fine branny desquamation The mother stated that about three weeks previously the child had a generalized rash accompanied with fever A diagnosis of postscarlatinal exfoliation was made Urinalysis at that time showed a faint trace of albumin

The patient returned to the clinic in July 1946 presenting a number of discrete, somewhat lichenified patches around both ankles Under treatment with bland ointments the condition improved over a period of two months

In March 1947 the patient again visited the clinic At this time he had an eruption on the ankles, elbows, knees and dorsa of the fingers (terminal phalanges) On the ankles there were areas made up of violaceous shiny papules, on the elbows and knees there were many small flesh-colored papules, some in linear arrangement along scratch marks (Koebner phenomenon) There were no lesions on the trunk or genitals A diagnosis of lichen planus and possible lichen nitidus was made

A specimen taken from a lesion of the right elbow showed the epidermis to be covered by a thin keratin layer The basal cells were heavily pigmented At one point, just beneath the epidermis, there was a localized collection of inflammatory cells, including mononuclear cells and polymorphonuclear leukocytes The epidermis overlying this nodule of inflammatory cells appeared somewhat compressed and thinned out The histologic picture was consistent with a diagnosis of lichen nitidus A roentgenogram of the chest showed no abnormalities Results of quantitative tuberculin (human and bovine) tests in dilution of 1 10,000 and 1 100,000 were negative Kahn and Kline reactions of the blood were negative The urine was normal

DISCUSSION

DR MAX JESSNER The question of the occurrence of lichen planus and lichen nitidus simultaneously is an old one The patient shows definite lichen planus on the ankles, the lesions on the arms resemble lichen nitidus At the outset the lesions look almost alike There have been cases reported in which the two types have been found together One should, however, have histologic evidence in order to corroborate both diagnoses I think that the picture in this case fits in with the lichen planus type, especially in view of the lesions on the ankle

DR PAUL GROSS The case is of interest because of the rare association of lichen planus and lichen nitidus The tissue was somewhat damaged in the preparation for histologic examination, and, therefore, a definite diagnosis of lichen nitidus could not be made The typical tubercle-like structure was lacking, but it may be that even in lichen nitidus a nonspecific granuloma is present in the early stage of the lesion

DR WILBERT SACHS Conclusions cannot be drawn from this slide I agree with the diagnoses of lichen planus and lichen nitidus I have seen 2 similar cases

DR JOSEPH L MORSE As Dr Gross pointed out, this case was presented because of the rare association of the two diseases The lesions around the ankles were certainly characteristic of lichen planus An effort will be made to obtain biopsy specimens from both types of lesions

Tinea Glabrosa, Dermatophytosis, Onychomycosis, Pityriasis Versicolor, Erythrasma and Tinea Versicolor Appearing in the Same Patient Presented by DR EMANUEL MUSKATBLIT and (by invitation) DR L TULIPAN

The patient, a white man aged 65, has been seen at the Clinic of the New York University presenting several types of fungous infection 1 On both cheeks, especially the left one, in front of the ears, there is a faint erythema and scaling of about three weeks' duration Scrapings showed fungi of the ringworm type 2 On the neck there is a faint erythema, scaling and hyperpigmentation of a few weeks' duration 3 The upper middle part of the chest shows erythema, scaling, hyperpigmentation and some lichenification of about two months' duration Scrapings from the left side of the neck and chest showed fungi of the ringworm type 4 On the back there is a brownish scaly patch with numerous brownish macules on the periphery The duration is unknown Examination of the scales showed Malassezia furfur 5 On the left thigh there is a brownish-reddish patch with slight scaling and small foci on the periphery, of ten years' duration Scales from the thigh showed Actinomyces minutissimus and M furfur 6 The soles and lateral aspects of the feet showed scaling The toes and webs showed scaling and maceration of ten years' duration The toe nails showed yellowish and grayish patches and dulness Scrapings from the feet, toes and right big toe nail showed fungi of the ringworm type Cultures were planted with material obtained from areas infected with ringworm

NOTE—The toes showed Trichophyton purpureum All other culture tubes failed to show pathogenic fungi

Pseudopelade (Brocq) (Lupus Erythematosus?) in a Woman Aged 47 Presented by DR ELLEN REINER

Alopecia Cicatrisata (Pseudopelade) in a Negro Woman Aged 38 Presented by DR. LEO SPIEGEL and (by invitation) DR A KORNBLEET

A Case for Diagnosis (Cylindroma? Nevus? Papilliferus Syringadenomatosus? Turban Tumor?) Presented by DR CHARLES WOLF

Charles Wolf, M D, *President*
Henry Silver, M D, *Secretary*
Oct 23, 1947

Mycosis Fungoides, Fungoid Stage, Treated with Antimony Preparations Presented by DR JOHN GARB

D N, a woman aged 49, was registered at the Skin and Cancer Unit of the New York Post-Graduate Medical School and Hospital on Jan 17, 1940, presenting lesions of two years' duration The eruption began on the left thigh with a red, nonitchy, oblong patch about 3 inches (8 cm) in diameter Several months later oozing vesicular and crusted patches appeared on the chest and, shortly after, on the neck On the trunk the patches were erythematous and covered with silvery scales and showed minute bleeding points At that time a diagnosis of psoriasis vulgaris was made

On Jan 7, 1942, the microscopic examination of a specimen taken from the left elbow showed chronic eczema

The patient was readmitted to the New York Post-Graduate Hospital on Jan 8, 1943 At that time she presented a generalized erythematosquamous eruption The lesions were sharply marginated, of various sizes and round or oval, and they formed bizarre patches by confluence Most of them were elevated above the level of the surrounding integument and were edematous and infiltrated

In February 1943 a section of a specimen taken from the left forearm was examined histologically by Dr C F Sims The epidermis showed moderate and somewhat irregular acanthosis, with areas of parakeratosis alternating with retained granular layer Moderate intercellular edema and cellular infiltration were visible In the upper part of the corium were numerous small dilated vessels with edematous and thickened walls surrounded by moderate cellular infiltration of a polymorphous character Small round connective tissue cells, epithelioid cells, histiocytes and plasma cells were present In the zone of infiltration there was moderate interstitial and parenchymatous edema The histologic diagnosis was mycosis fungoides

The hemogram was normal, and the eosinophil count, 5 per cent The Wassermann reaction of the blood was negative The sedimentation rate was 10 mm per hour (normal in women, 19 mm per hour), as determined by the Westergren method Tests with old tuberculin elicited negative reactions in dilutions down to 1 5,000 and a plus-minus reaction in a dilution of 1 1,000 The icteric index was normal Roentgenograms of the chest revealed isolated old, calcified, central and parenchymal tubercle scars

During the seven years of observation the therapeutic measures included adequate courses of superficial fractional roentgen radiation exposures, courses of ultraviolet irradiation, and the administration of testosterone, oxophenarsine hydrochloride (mapharsen®) calciferol (vitamin D_2), promin® (sodium p,p'-diaminodiphenylsulfone-N,N'-didextrose sulfonate) intravenously and locally, bismuth subsalicylate, ethyl chaulmoograte, diphtheria toxoid, sodium arsenate, resin of podophyllum, riboflavin, ascorbic acid and anterior pituitary extract

During these years the patient showed no spontaneous remission of any of the lesions There was some temporary regression due to the roentgen irradiation or to some of the other therapeutic agents There was a tendency for most of the lesions to recur in a more aggravated form, and new lesions continued to develop

On April 28, 1947, treatment with antimony potassium tartrate was instituted On May 19, 1947, after ten intravenous injections of 5 cc of a 1 per cent solution of antimony potassium tartrate, given three times weekly, there was spectacular improvement The superficial patches were rapidly undergoing involution, and the raised growths were flattening out

From June 4 to August 8, because of possible toxic reactions, the treatment was changed to triweekly intramuscular injections of stibanose® (the diethylamino ethanol salt of sodium antimony gluconate), 4 cc per dose, the compound being a pentavalent antimony preparation containing 20 mg of antimony per cubic centimeter A total of nineteen injections was given On August 6, the patient was about 80 per cent improved

Electrocardiograms were taken every two to four weeks On August 11 minimal myocardial changes were observed Treatment with stibanose® was discontinued and crude liver extract and thiamine hydrochloride were given

On October 4 the electrocardiogram did not reveal any abnormalities of the ventricular complexes Injections of stibanose® were resumed twice weekly, alternating with administration of liver and thiamine hydrochloride

Examination on October 17 showed that all lesions, except for an isolated few, had completely regressed, leaving faintly superficial, reddish to purplish spots and dark brown patches The breasts, except for two small superficial patches, were entirely clear, the foul-smelling, crusted patches were replaced by normal epidermis A nodular growth on the middle of the left leg remained unchanged

DISCUSSION

DR FRANK E CROSS I should like to ask Dr Garb for the rationale of the use of antimony salts in the treatment of mycosis fungoides

DR JOHN GARB During the past five years I have experimented with many forms of treatment in mycosis fungoides, including promin,® testosterone propionate, diphtheria toxoid, chaulmoogra oil and many others The effect of these measures was only partial and temporary The use of antimony salts was purely experimental, prompted by the success obtained with them in treatment of granuloma inguinale The rapid melting of the ulcerated growth in mycosis fungoides (50 per cent improvement within three weeks) exceeded my expectation

DR CHARLES F SIMS I have examined several sections of specimens obtained in this case One of them presented a pleomorphic cellular infiltration in the upper part of the corium, as well as other histologic changes consistent with the diagnosis of mycosis fungoides

DR SAMUEL M PECK If this is truly a case of mycosis fungoides—and I value Dr Sims' opinion—then the treatment with antimony salts would rank as one of the important contributions to modern therapy It is well known that mycosis fungoides is a type of lymphoblastoma I hesitate to admit that the lymphoblastomatous type of lesion would respond to such a therapeutic measure If the antimony salts really have a beneficial effect on mycosis fungoides, it would be necessary for this disease to be removed from the group of lymphoblastomas I do not believe, however, that antimony salts would have such a beneficial effect on malignant lesions I have treated a variety of dermatoses, principally psoriasis, with antimony salts and have seen such cases clear up after one treatment However, recurrent lesions are resistant to antimony Further trial with antimony salts in treatment of mycosis fungoides is certainly indicated

DR BORRIS A KORNBLITH (by invitation) I have had much experience with antimony compounds, especially in the treatment of granuloma inguinale I have employed antimony potassium tartrate, stibophen (fuadin®), antimony sodium thioglycollate and stibanose® Since granuloma inguinale is a chronic disease and requires a prolonged period of therapy, a number of pertinent observations were possible in evaluating these antimony preparations

It is possible for one to give any of the antimony preparations up to a point of toxicity and to continue with a subtoxic dose for long periods because of the rapid excretion of these compounds through the kidney (for the most part, 80 per cent in twenty-four to forty-eight hours) and through the bowel (10 per cent) For cases requiring larger dosage for maximum therapeutic effect, stibanose® is by far the most advantageous drug There is no pain associated with its subcutaneous or intramuscular administration, while the other antimony preparations, such as antimony potassium tartrate, stibophen and antimony sodium thioglycollate, produce pain when given intramuscularly In general, it may be stated that larger doses of antimony are not possible because of the toxicity of the drug When a less toxic drug is introduced, the larger doses are well tolerated and a better

therapeutic result obtained Initial resistance to antimony, however, is not overcome by increasing the dose

The immediate toxic reactions, in the order of their appearance, are as follows hacking cough, circumoral pallor, blanching of the face, respiration, nausea, retching, vomiting and vasomotor collapse All these symptoms are ameliorated by the prompt use of epinephrine subcutaneously (8 to 10 mm of a 1 1,000 solution) The late symptoms of toxicity are myalgia, especially of the deltoid and the quadriceps femoris muscles, pain along the distribution of the trigeminal nerve, especially in decayed teeth, and cardiac irregularities, such as bradycardia and auricular fibrillation, with occasional electrocardiographic changes

All observations were made on ambulatory patients, who tolerated the antimony drugs in a surprisingly asymptomatic way despite the large doses used

DR JOHN GARB I am in accord with Dr Peck If treatment with antimony preparations should prove effective in other cases of mycosis fungoides, then mycosis *fungoides should be taken out of the group of lymphoblastomas*

Similar remedies, such as chaulmoogra oil, are sometimes used in the treatment of leprosy and of mycosis fungoides It is interesting to note that antimony salts, alone or in combination with arsenic, have been used in the treatment of leprosy, with varying degrees of success, by Kingsbury and others (A New Antimony Compound in the Treatment of Leprosy, ARCH DERMAT & SYPH **24** 1053 [Dec] 1931)

As Dr Kornblith pointed out, the pentavalent antimony preparation stibanose® is the least toxic of all antimony products Nevertheless, toxic reaction, especially myocardial damage, must be guarded against

Keratosis Follicularis (Darier's Disease) *Presented by* DR NATHAN SOBEL

D N, a girl aged 14, presents an eruption which has been present for seven years, but which has become aggravated in the past four years The patient has no brothers or sisters The mother, father and other relatives are not affected by the disease

In both supraclavicular regions and on the sides of the neck there are areas of erythema the size of a palm, with extensive oozing and yellowish crusting The scalp and upper part of the forehead show similar areas There are numerous discrete keratotic lesions the size of a pinhead in the perioral region and also on the neck

Histologic examination on May 3, 1947, showed pronounced hyperkeratosis and an increased granular layer in some areas Classic corps ronds and grains were present in some sections There were lacunas just above the basal cell layer and also within the prickle cell layer in many areas The histologic diagnosis was keratosis follicularis (Darier's disease)

At the clinic the patient received injections of liver extract, potassium arsenite solution (Fowler's solution) and vitamin A by mouth During the summer of 1947 she also had ten intramuscular injections of a preparation containing 100,000 units of vitamin A, given triweekly, with little benefit Since Sept 4, 1947, she has been treated at my office Treatment has consisted of administration of a compound containing 200,000 units of vitamin A daily by mouth in combination with ox bile extract (bile salts) Six roentgen ray treatments were given to the supraclavicular regions and neck There has been moderate improvement However, the patient states that the condition is at its worst in the summer

DISCUSSION

DR NATHAN SOBEL A diagnosis of familial benign chronic pemphigus (Hailey and Hailey) was considered in this case, but the diagnosis of keratosis follicularis was established on the basis of histologic findings The patient is presented because of the failure of the condition to respond to large doses of vitamin A and liver

DR SAMUEL M PECK There are two curious facts that stand out in the treatment of keratosis follicularis with large doses of vitamin A (1) there is a peculiar relation between keratosis follicularis and exposure to light, and (2) some patients who do not respond to oral therapy respond to injections

Exposure to sunlight causes aggravation of the eruption and, at times, vesiculation My patients learn soon enough not to go to the beach It is my experience that lesions on the exposed parts, such as the forehead, face and neck, are more resistant and clear much later than those in comparatively protected areas, such as the axillas It is evident that the light factor plays an important role

Some cases which do not respond to vitamin A therapy alone do respond to treatment with a combination of vitamin A and members of the vitamin B complex This fact was called to my attention by Dr Gross Vitamin B metabolism apparently plays a role in the second factor If some patients do not respond to treatment with vitamin A, it should be supplemented by injections of liver and large doses of nicotinic acid

DR CHARLES R REIN In other cutaneous conditions associated with vitamin A deficiency, the administration of large doses of vitamin A orally did not produce a beneficial effect until absorption from the gastrointestinal tract was implemented by the concomitant ingestion of dilute hydrochloric acid Such a regimen might be effective in treatment of this patient

DR HANS STORCH, Zurich, Switzerland (by invitation) A case of keratosis follicularis recently under observation at the University Clinic in Zurich has responded remarkably well to treatment with grenz rays

DR NATHAN SOBEL With respect to Dr Peck's remarks regarding exposure to light and keratosis follicularis, I can state that this patient's condition had been aggravated during the summer Since it is believed that sunlight has a bad effect *on this condition*, another patient under my observation was kept out of the sun's rays but failed to improve I also exposed a small area of the back of that patient to ultraviolet rays in erythema doses, but no new papules have formed I believe there must be some factor other than sunlight to aggravate the condition during the summer months The patient I presented tonight also failed to improve by avoidance of sunlight She has already been given injections of crude liver extract I shall, however, follow the suggestions of Drs Peck and Rein and try treatment with nicotinic acid and hydrochloric acid I may also try the use of grenz rays, as suggested by Dr Storch

Livedo Reticularis, with Recurrent Superficial Ulcerations of the Feet Presented by DR SAMUEL M PECK and DR KAI K LI (by invitation)

Purpura Annularis Telangiectodes (?). Presented by DRS PAUL GROSS and ELLEN REINER

A Case for Diagnosis (Epidermodysplasia Verruciformis?) Presented by DRS MAX JESSNER and CHARLES R REIN

E W, a man aged 21, presents an eruption of five years' duration It began as a few discrete lesions on the forehead and reached the present stage within a few months The patient has received various types of therapy, including peeling, administration of wart vaccine and roentgen irradiation, with no appreciable change

His parents are nonrelated He states that his older sister has wartlike lesions on the fingers which have persisted for the past several years

The eruption is most conspicuous on the face and consists of discrete, light brown, nonscaly papules varying in size from that of a pinhead to that of a pea Many of these lesions are made up of groups of smaller lesions, some of them taking on an annular configuration The lesions over the bearded portion of the chin are quite characteristic of verruca plana There is a solitary verrucous lesion, the size of a large pea, on the dorsum of the left hand Several of the lesions were destroyed by electrodesiccation and curettage, which resulted in keloidal scarring A lesion of the forehead was removed for microscopic examination Dr C F Sims reported that the epidermis was moderately verrucous There was some elongation and broadening of the rete pegs at many points Considerable vacuolation of the cells of the granular layer and the upper rete cells was observed No noteworthy changes were present in the corium

DISCUSSION

DR EMANUEL MUSKATBLIT The lesions impress me as ordinary verrucae planae What clinical features justify the other diagnosis?

DR HENRY SILVER I hesitate to make a diagnosis of epidermodysplasia verruciformis in this case, but I should definitely rule out verruca plana I admit that the histologic evidence, such as ballooning of the cells and the basket weave appearance of the epidermis, is characteristic These features, however, are not limited to epidermodysplasia verruciformis but are seen in other diseases, such as verruca senilis, mal de Meleda and molluscum contagiosum, and even in common warts We cannot, therefore, rely solely on the histologic evidence Because of our lack of knowledge regarding etiology of the disease, it is difficult and often confusing to separate the clinical varieties encountered These variants of localized or region-specific keratoses are often considered as separate entities on flimsy evidence It is highly probable that epidermodysplasia verruciformis of Lewandowsky and Lutz, Hoffman's verrucosis generalisata and possibly Hopf's acrokeratosis verruciformis are clinical variants of the same disease

The well developed cases of epidermodysplasia verruciformis are readily diagnosed Most of the characteristic features, such as the disseminated, verruca-plana-like lesions, the tendency to malignant transformation, the verruca-vulgaris-like lesions and the verrucous plaque formations, are usually present The case I presented before the Section of Dermatology of the New York Academy of Medicine was a fairly characteristic example of the disease (Epidermodysplasia Verruciformis, ARCH DERMAT & SYPH **45** 836 [Nov] 1941) Dr Rein's case lacks some of the clinical features I would therefore consider his case a forme fruste of the disease

DR PAUL GROSS In spite of the fact that the diagnosis epidermodysplasia verruciformis is still in doubt, I should definitely rule out the suggested diagnosis of verruca plana on clinical grounds

DR DAVID BLOOM From the appearance of the lesions, it is difficult for one to make a diagnosis of epidermodysplasia verruciformis, but one has to favor this diagnosis because of the plaque formation on the face The vacuolation of the epidermal cells seems on histologic examination to support the diagnosis as presented, although such changes are reported also in verruca plana and in other keratotic and dyskeratotic conditions I should like to call attention to the type described in the French literature as *erythrokératodermie verruqueuse en nappes*

DR. CHARLES LERNER In my opinion this is a case of verruca plana, if I may judge from the lesions that I observed on the dorsum of the left hand

DR MAX JESSNER I have little to add to Dr Silver's remarks Dr Rein and I expected a difference of opinion about this case, and for this reason we presented the patient The question of whether epidermodysplasia verruciformis is a dermatosis *sui generis* has become acute again since W Lutz's article appeared in *Dermatologica* in 1946 Epidermodysplasia verruciformis had already once to fight for its existence and nevoid nature when it was confronted with verruca disseminata and verrucosis generalisata, respectively At that time it had, we believed, won the fight Such cases as Lewandowsky and Lutz's first one, which I saw, are impressive, and their nevoid and rather often precancerous nature ought not to be doubted A case not as widespread, with several epitheliomas, shown to me by Dr de Cholnoky, will be presented at a subsequent meeting It is the more or less abortive forms resembling clinically verruca plana which are difficult to diagnose, especially if the vacuolation of the rete cells is not outstanding and because of the fact that a certain degree of vacuolation may also be found in warts In the case presented it is the clinical aspect, especially the confluence of the lesions in some parts of the affected region, and the course of the disease, together with the histologic features, that favor a diagnosis of epidermodysplasia verruciformis

DR CHARLES R REIN I have learned that the patient's sister also had verrucous lesions on the hands If this point is confirmed, it will corroborate the diagnosis as presented The differential histologic diagnosis lies between verruca plana and epidermodysplasia verruciformis The clinical findings, history and course of the condition must be taken into consideration before a definite diagnosis can be established

Parapsoriasis Varioliformis Presented by DR FRANCES PASCHER

Juxta-Articular Nodes in a Patient with Neurosyphilis Presented by DR JULIUS H POLLOCK

Basal Cell Epithelioma of the Nipple of a Man Presented by DR NATHAN SOBEL

L S, a man aged 46, has been a patient at the Skin and Cancer Unit of the New York Post-Graduate Hospital since Sept 19, 1947 The duration of the lesion is not definitely known, but the condition has been present for at least several years When the patient was first seen at the hospital there was in the area of the right nipple a scaly and somewhat crusted noninflammatory lesion the size of a dime The diagnosis of carcinoma simplex (Paget's disease) of the nipple was considered At present the entire right nipple and adjoining areola show an infiltrated plaque with an irregular surface

The Wassermann reaction of the blood was negative on Sept 19, 1947 Microscopic examination made by Dr C F Sims, showed that the epidermis was eroded

in one area Below it there was a large mass made up of groups and strands of basal cells The palisade layer was intact There was a slight inflammatory infiltrate in the midcutis

DISCUSSION

DR CHARLES F SIMS I have examined the slide, and there is no question that it is of basal cell carcinoma

DR HENRY SILVER I suggest that the condition be subjected to the Mohs method of therapy

DR FRANK E CROSS Cancer of the breast in the male is more malignant than is that in the female It is rather uncommon in the male and is usually of the prickle cell type I do not question the histologic report, but in view of the previous statement I feel that one must be more radical in therapy I should, therefore, suggest a wide excision of the nipple, followed by the making of serial sections of the specimen removed for further histologic study

DR CHARLES F SIMS Dr Cross's suggestion of a possible prickle cell epithelioma was not substantiated by the histologic findings

DR NATHAN SOBEL When first seen the lesion was scaly and crusted, and the diagnoses that were considered were chronic eczema, possibly Paget's disease and keratosis of the nipple Tonight the lesion looks clean and somewhat nodular, and it is difficult to make the diagnosis on clinical grounds alone

As Dr Cross stated, basal cell epithelioma of the nipple in the male is a rare condition Dr Arthur Hyman reviewed the literature and could find only the following references to its occurrence Elliott and Welland (ARCH DERMAT & SYPH **53** 322, 1946) reported not a single case of basal cell epithelioma of the nipple among 1,928 cancers of the skin In 1924, Wainright (*Arch Surg* **14** 844, 1927) reviewed 264 cancers of the male breast and found only 1 case of basal cell epithelioma in the series In this series there were only 6 prickle cell epitheliomas, so even prickle cell epithelioma of the nipple is rare Geschickter (Diseases of the Breast, Philadelphia, J B Lippincott Company, 1943, p 603) refers to a reported case of basal cell epithelioma in the female breast mentioned by Ewing Dr Hyman informed me that he has personally seen 1 case of basal cell epithelioma of the male nipple and adjoining areola which was clinically diagnosed as Bowen's disease

After the lesion is removed, serial histologic sections will be studied

FOLLOW-UP NOTE Serial sections showed only basal cell epithelioma

Multiple Pigmented Nevi Presented by DR CHARLES WOLF

Poikiloderma of Civatte Presented by DR HARRY B FEILER

PHILADELPHIA DERMATOLOGICAL SOCIETY

J M Schildkraut, M D, *Chairman*

Douglass A Decker, M D, *Secretary*

April 18, 1947

Herpetic Stomatitis and Vaginitis (Pemphigus?) Presented by DR JOHN F WILSON

Scleroderma with Calcinosis Presented by DR CARMEN C THOMAS and (by invitation) DR DAVID KREMER

Blastomycosis with Pulmonary Involvement. Presented by DR CARMEN C THOMAS and (by invitation) DR G H WELLS

Cutaneous Diphtheria Presented by DR CLARENCE S. LIVINGOOD and (by invitation) DR HARVEY BLANK

C L, a white man aged 25 years, presents healed, round scars on both legs, approximately 1 inch (2 cm) in diameter, with brownish, pigmented, atrophic centers On July 10, 1944, five weeks after the patient's arrival in Burma, ulcers appeared on both legs On August 3 he was admitted to the 69th General Hospital, Assam, India, with multiple, punched-out ulcers with a tough black eschar and a rolled bluish red border On October 1 numbness and weakness of the fingers, toes, hands and feet appeared By October 31 the skin had healed, and by December 30 the neuritic symptoms had cleared

The smears taken from the ulcers did not show fusiform bacilli or spirochetes Cultures were not available, but virulent Corynebacterium diphtheriae were cultured from many other patients with the same type of lesion

The patient was treated with various bland local measures and bed rest As the result of his Schick test was negative, no antitoxin was given

DISCUSSION

DR CLARENCE S LIVINGOOD This is a patient whom Dr Blank saw from the onset of his illness The scars are typical postdiphtheritic ones Other ulcerative lesions can leave scars, but with experience one can identify the postdiphtheritic type We had difficulty in convincing our colleagues that cutaneous diphtheria produced ulcers that are diagnostic Any dermatologist who is accustomed to seeing and making fine distinctions between ulcerative lesions can make this diagnosis without difficulty Anthrax, first degree burns and trophic ulcers can produce somewhat similar scars, but I do not believe that any other conditions produce ulcers of this type

A Case for Diagnosis (Poikiloderma Atrophicans Vasculare?). Presented by CAPTAIN ROBERT L GILMAN, United States Navy

Parapsoriasis en Plaques Presented by DR LEWIS M JOHNSON

R J, a white man aged 19 years, noticed an eruption on his lower extremities shortly after an attack of severe bronchitis in the spring of 1945 There have been no subjective symptoms The lesions started as small macules and gradually progressed in size and number and occurred on his upper extremities together with an associated loss of pigment During the summer of 1946 the eruption on his upper extremities faded considerably, but recurred during the past winter The history reveals no prolonged ingestion of drugs prior to the onset of the eruption except for "drops" for his heart The patient is well built and presents variously sized, round and oval, pinkish to copper-colored, macular lesions, some of which have a fine scale and a reticulated appearance They are more profuse on the lower extremities, those on the upper extremities have an associated patchy loss of pigment in the surrounding skin These lesions, when viewed with filtered ultraviolet rays ("black light"), are darkened and more pronounced on the lower extremities and have a faint fluorescence on the upper extremities The results of the rest of the physical examination were essentially normal except for a soft mitral systolic murmur, a chronic macerated and fissured eruption between the toes of both feet and hyperhidrosis of the hands and feet

A complete blood cell count revealed 93 per cent hemoglobin (14 73 Gm), 4,870,000 erythrocytes, 11,600 leukocytes, 71 per cent polymorphonuclear leukocytes and 29 per cent lymphocytes The result of the Kline test of the blood for syphilis was negative The potassium hydroxide preparation of the scales did not reveal fungi A urinalysis showed no abnormalities

DISCUSSION

DR MEYER L NIEDELMAN I suggest the diagnosis of erythema multiforme perstans The lesions have been present for two years, are sharply marginated and on diascopic pressure become rather light, and the surrounding tissue seems to have some pitting edema

DR FRITZ CALLOMON (by invitation) The diagnosis of parapsoriasis appears acceptable This form corresponds to Brocq's erythrodermie pityriasique en plaques disseminees and the yellowish color with the English description of Radcliffe Crocker's xanthoerythroderma perstans Although the lesions of Brocq's disease usually persist unchanged over many years, seasonal changes were observed by Civatte, White and Brocq himself, who described obvious remission during the summer and exacerbation during the winter months (Jadassohn, J Handbuch der Haut- und Geschlechtskrankheiten, Berlin, Julius Springer, 1928, vol 7, pt 1, p 388)

DR BERTRAM SHAFFER This eruption has a peculiar artificial appearance I suggest the diagnosis of factitial eruption The lesions are sharply demarcated and regular, and all of them are disposed on parts of the body accessible to the patient

DR DONALD M PILLSBURY I agree with Dr Shaffer The pharyngeal and corneal reflexes are absent Some of the lesions have disappeared, which is against the diagnosis of parapsoriasis If it turns out that the patient has parapsoriasis, I suggest a trial of anthralin to the point where it produces some reaction This case is similar to one Dr Kulchar had in our clinic some years ago, the only one of parapsoriasis which cleared up with treatment with anthralin (dihydroxyanthranol)

DR LEWIS M JOHNSON, Lancaster, Pa I cannot agree that the patient produced the lesions on the backs of the arms, nor can I understand the depigmentation I thought of a fixed type of eruption when I saw him first in November I shall let you know the report of the biopsy

NOTE—The diagnosis from the biopsy was parapsoriasis (Lancaster General Hospital)

Sporotrichosis Presented by DR J M SCHILDKRAUT, Trenton, Pa

Recurrent Lupus Erythematosus Presented by DR H E TWINING

J C, a Negro man aged 30 years and well nourished, presents sharply marginated, eczematous, slightly scaly patches of dermatitis on the cheeks, nose and mucous membranes of the mouth of about four months' duration The original lesions almost completely disappeared with treatment with bismuth subsalicylate injections and liver This is the third recurrence, all the lesions appearing at the original sites A small, erythematous area developed on the bridge of the nose in 1943 This was diagnosed as eczema Three months later it recurred with erythematous scaly lesions sharply demarcated on the nose and cheeks

A roentgenogram of the chest did not show tuberculosis Treatment with injections of bismuth compound and liver was successful in previous attacks but produced no improvement in the present one

DISCUSSION

DR CHARLES R REIN, New York (by invitation) I have used bismuth sodium triglycollamate (bistrimate®) in a number of conditions, including lupus erythematosus, lichen planus, verruca and granuloma annulare Best results were obtained in patients with lupus erythematosus Two patients with this condition showed no improvement after many intramuscular injections of bismuth subsalicylate but responded well to oral treatment with bismuth sodium triglycollamate This preparation was also efficacious in some patients with acute generalized lichen planus, but the results in the other diseases were disappointing

DR H E TWINING I tried bismuth sodium triglycollamate in this patient but had to discontinue it because of the occurrence of stomatitis and gingivitis Has Dr Wright seen many patients who cannot tolerate this drug?

DR CARROLL S WRIGHT My co-workers and I have the same percentage of intolerance with this preparation as with bismuth given in any other form

DR MEYER L NIEDELMAN At the last Atlantic Dermatological Conference suramin sodium (naphuride®) was mentioned for the treatment of lupus erythematosus It would be worth while to try it in this patient, if bismuth preparations prove ineffective

DR STEPHEN WHELAN (by invitation) In a total of about 25 patients with discoid lupus erythematosus my co-workers and I have used bismuth sodium triglycollamate in the past year and a half and we have not had the favorable results that Dr Wright and Dr Gross have reported We had 2 cases of hypertrophic lichen planus with good results in which the disease had not responded to bismuth compound administered intramuscularly

Multiple Large Keloids. Presented by DR MEYER L NIEDELMAN

E R, a white man aged 25 years, has a large, thick, keloidal band on his neck It is lobulated and adherent and limits the motion of the chin There are a number of small keloids on the cheek, chest, back and arms and on the vaccination site There are no lesions on the lower extremities On the forehead, cheeks and nose there are numerous hyperpigmented macules from pinpoint size to pea size, which the patient stated have been present since birth He had a burn from hot water on the neck at the age of 8 years, the past history is otherwise normal At the age of 12 the patient first noticed the keloids about the neck Shortly thereafter papules developed on the right side of his face, which subsequently developed into keloids He sustained a human bite on the sternal area at the age of 16, which developed into a keloid

In 1943, at another institution, the entire keloid on the neck was surgically removed, sutured and treated with roentgen rays This region shortly grew larger than the original In 1944 the keloid on the left side of the neck was similarly treated, that on the right side of the neck was operated on in September 1944, with a skin graft from the right thigh A keloid developed at the donor site

DISCUSSION

DR. J P SCULLY (by invitation) This patient shows two different types of scar The question arises whether endocrine disturbances are a factor in the production of keloidal change and whether, if further surgical attempts were made in this case, it might be well to attempt the coincident injection of diethyl

stilbestrol or male sex hormone during the postoperative period It was suggested that one lesion, possibly the one on the sternum, be excised in trial treatment and then some type of therapy determined In one case irradiation was suggested I should like to see diethyl stilbestrol or some similar preparation tried in order to determine whether the keloidal aftermath might be prevented

DR IRA L SCHAMBERG Are keloids ever seen before puberty? Children suffer all sorts of trauma, and, if they are not seen, Dr Scully's suggestion has some merit

DR DONALD M PILLSBURY I have seen many keloids in children

DR MAX JESSNER, New York (by invitation) I had a keloid when I was a small boy, but not since then Keloid formation is due to a "fibrotic" tendency of the organism, and that may change I do not believe that we know the reason for this, but many things have been suggested There has been a report by a physician who cured keloids by the administration of sodium fluoride (Callam, M *Munchen med Wchnschr* **82** 1534, 1935) I tried it in a case and had the impression that it did good I was afraid, however, to give it in large doses

CAPTAIN ROBERT L GILMAN, United States Navy I have seen keloids in children 4 to 8 years of age

DR THOMAS BUTTERWORTH, Reading, Pa Keloids do occur in children I am treating a keloid now in a youngster The statement occurs in some books that keloids tend to undergo involution after the menopause I have seen a keloid develop in the breast of a school teacher about 55 years of age For the case presented today I recommend Dr H J Smith's 2 per cent menthol in cottonseed oil with massage

DR DOUGLASS A DECKER, Allentown, Pa Dr Smith stated that the menthol and cottonseed oil preparation helps only those patients with itching or pain in the keloid

Psoriasis, with Extensive Koebner Phenomenon Induced by Systemic Reaction to Sulfadiazine Applied Locally to Burn Presented by DR LESLIE NICHOLAS and (by invitation) CAPTAIN RAYMOND R SUSKIND

Trichophyton Purpureum and Monilia Infection of the Hands, Feet and Nails Moniliasis of the Tongue Presented by DR LESLIE NICHOLAS and (by invitation) CAPTAIN RAYMOND R SUSKIND

Pigmented Purpuric Lichenoid Dermatitis Presented by DR LOUIS GOLDSTEIN

S W, a white man aged 29 years, presents on both legs many smooth, small, slightly elevated papules, some of which fuse into poorly marginated patches They are reddish brown The condition began about six months ago on the latero-anterior aspect of the left leg as a reddish, flat, papular, quarter-sized lesion with no subjective symptoms and gradually progressed to the present size

DISCUSSION

DR FRED D WEIDMAN I think we were all struck by the extremely lurid color of these lesions, in six months there certainly ought to be some pigmentation, yet there is not In the sections there is not any sign of hemorrhage to explain the extreme redness nor is there any pigment One must explain the redness on some other basis than that, and it is known that sometimes infiltrations of cells will produce a red color, for example, the small red kidney in chronic interstitial nephritis There is not any particular vascular hyperplasia, and there is no hemorrhage, but there is something different in the constitution of the cells which in the aggregate makes them red That was one of the things that puzzled me in this case Microscopically certain features suggest lichen planus, like the sharp demarcation of the zone underneath, but cellular infiltration is sparse for that, considering that these are fresh lesions, yet they are so highly elevated and delicately nodular or papular They are not in a regressive stage They are not atrophic lesions If this were lichen planus it would have to be atrophic lichen planus, and that is contrary to what this patient presents There are many histiocytes, and I do not know what the significance of those may be except that they tend to assist in eliminating lichen planus as a diagnosis The grouping is not discoid, as it should be in Majocchi's disease, and the lesions are not hemorrhagic In this type there should be some pigmentation There is a slight scaliness, but in the Gougerot-Blum complex I think that there should be more scaliness than is shown here I think that this is a puzzling case, and I cannot give a specific diagnosis

A Case for Diagnosis (Leukemia?) Presented by DR THOMAS BUTTERWORTH, Reading, Pa

Extensive Verruca Plantaris, Verruca Vulgaris Presented by DR J M SCHILDKRAUT, Trenton, N J

DISCUSSION

DR C S LIVINGOOD I suggest that the patient soak his feet daily in a solution of formaldehyde It is well to use 4 per cent formaldehyde for only a minute or so at first and gradually increase the time to four or five minutes, depending on the reaction

DR THOMAS BUTTERWORTH, Reading, Pa I often advise patients to apply 60 per cent salicylic acid paste and bandage the foot for about three days and then rub in 30 per cent salicylic acid paste nightly with the round head of a clothes pin, this seems to be effective

DR ISADORE ZUGERMAN Has the patient had bismuth sodium triglycollamate?

DR J M SCHILDKRAUT, Trenton, N J He has had bismuth subsalicylate injections

DR THOMAS BUTTERWORTH When treating a patient with formaldehyde solution, one must be sure that the fluid is not much more than a ¼ inch (0 64 cm) deep

Tuberculosis Verrucosa Cutis Presented by DR SIMON KATZ and (by invitation) DR PETER HORVATH

Trichophytosis Barbae Presented by DR M H SAMITZ and (by invitation) DR LAWRENCE KATZENSTEIN

Pityriasis Rubra Pilaris Presented by DR CARROLL S WRIGHT and DR MEYER L NIEDELMAN

E F, a Negro woman aged 39 years, first had a severe sore throat and a painful right shoulder about two months ago She used a gargle several times daily, consisting of a solution of 1 teaspoonful of salt and several drops of iodine About two weeks ago swelling of the face, puffiness of the eyes and scaling of the scalp developed The eruption on the arms and body followed After the eruption appeared she received several injections of an unknown substance There is an acute inflammatory dermatitis of the face and edema of the periorbital areas with pronounced conjunctivitis The scalp and other hairy areas show scaliness On the extensor surfaces of the arms, shoulders, nucha and legs is a widespread discrete follicular keratotic eruption There is little itching There is no history of ingestion of drugs The Wassermann reaction of the blood for syphilis was negative

DISCUSSION

DR. HERMAN BEERMAN This is lichen planus

DR STEPHEN T WHELAN (by invitation) Some manifestations of the disease are incompatible with the diagnosis of lichen planus The process began on the face with edema and scaling, shortly after the patient had been to the hair dresser She also has scaling on her palms This is an allergic reaction to something that has been applied to the patient's hair

DR. C S LIVINGOOD Both Dr Beerman and Dr Whelan are right The patient has a Koebner phenomenon at the sites of her shoulder straps She may have both contact dermatitis and lichen planus

DR MEYER L NIEDELMAN Pityriasis rubra pilaris may have an acute explosive onset, it may start on the scalp and travel to the face I believe that this is a case of pityriasis rubra pilaris with a sudden and acute onset The patient has had no medication and has gone to the beauty shop many times before, with no ill effect The plugs and the involvement of the hairy areas are in accord with that diagnosis

DR D M SIDLICK I do not recall seeing in any reports or textbooks pityriasis rubra pilaris characterized by lichenoid lesions, and, if this is such a case, we shall have to change our concept once again

DR FRED D WEIDMAN There is a condition known as lichen planopilaris, maybe that would reconcile the different diagnoses that have been advanced In the histologic sections it was found that the lichen planus changes do extend down around the hair follicles, making them unduly prominent At the Naval Hospital there was a patient who had a patch of hypertrophic lichen planus on the thigh, and in one there were definite pits, which made me think at first of those which occur when one pulls out a plug from a lesion of Darier's disease These were located at the orifices of hair follicles I would suggest that the patient be examined with respect to a diagnosis of lichen planopilaris, which would bridge the two separate diagnoses advanced

DR LOUIS GOLDSTEIN I thought that lichen planopilaris had to do with the scalp and not with the glabrous parts of the body

DR. HERMAN BEERMAN The typical lesions of lichen planopilaris do occur on the wrists usually

NOTE—Microscopic examination of a biopsy specimen by Dr Fred D Weidman and by Dr Ernest Regertis resulted in a diagnosis of pityriasis rubra pilaris

Scleroderma in an Infant. Presented by DR J. M. SCHILDKRAUT, Trenton, N J.

A B, an infant 1 week of age, has had an eruption on the back since birth Examination shows hard, infiltrated plaques on the upper part of the back, anterior aspect of the chest and the right cheek

DISCUSSION

DR. CARMEN C THOMAS I suggest the diagnosis of subcutaneous fat necrosis of the newborn The lesions were present at birth, after a difficult labor lasting a day and a half, with delivery finally accomplished by forceps The lesions are deep seated, with the periphery beginning to show gradual involution

DR D M SIDLICK Scleroderma in an infant 1 week old would be accompanied by clinical evidence of systemic involvement The tense, edematous skin as well as the distribution and its presence since birth are more in consonance with the diagnosis of scleredema than scleroderma

DR FRED D WEIDMAN I offer an alternative diagnosis of lipophagic granuloma

DR J M SCHILDKRAUT, Trenton, N J Dr Klauder thought that the patient had scleroderma

DR H H PERLMAN I have seen a good many cases of so-called subcutaneous fat necrosis in the newborn The condition is usually described as sclerema neonatorum by many writers (misnomer) The mother stated that she had had an unusually difficult and prolonged labor It is for this reason that trauma should seriously be considered as a causative factor The condition appears a few weeks after birth and invariably disappears spontaneously, usually after a few months Someone mentioned sclerema neonatorum I do not think that this is a case of sclerema neonatorum, because that is a congenital condition or appears soon after birth (usually between the second and tenth day after birth) The condition affects the lower extremities and then spreads to the trunk In sclerema neonatorum, on pressing the affected sites one gets the impression that one is prodding the skin of a cadaver, the skin feels like half-frozen tissue Most patients with such a condition die early The lesions are rather extensive in this case, which is strongly in favor of subcutaneous fat necrosis If this is not a case of subcutaneous fat necrosis, then I would endorse the diagnosis of scleroderma

Douglass A Decker, M D, *Secretary*

Sept 19, 1947

Multiple Benign Cystic Epithelioma in a Girl Aged Eight Years. Presented by DR LEWIS M JOHNSON, Lancaster, Pa

A Case for Diagnosis (Angioma?). Presented by DR JOHN F WILSON

A J, a white woman aged 49 years, has a group of small red papules in the middle of the flexor surface of the left forearm The color can be pressed from the lesions, and the intervening skin is erythematous In August 1945, the patient had an appendectomy and right oophorectomy for simple ovarian cyst and appendicitis In April 1947, an exploratory laparotomy and transverse colostomy

were performed for postoperative adhesions and diverticulitis of the middle part of the sigmoid In August 1947, resections of the sigmoid were done for adenocarcinoma with metastasis to the regional lymph nodes The patient noticed a small red spot in the middle of the left forearm a year ago This remained about the same until May 1947 After an exploratory laparotomy the lesion spread, the present eruption has existed for several months

A blood cell count revealed 78 per cent hemoglobin, 4,300,000 erythrocytes and 6,000 leukocytes The urine was normal The Wassermann and Kahn reactions of the blood were negative The blood urea nitrogen was 13 2, plasma proteins 6 15, albumin 4 29 and globulin 1 9

DISCUSSION

DR FRED D WEIDMAN I think that it is necessary to see the sections for the diagnosis They show clearly the structure of a capillary angioma It is not a solitary large tumor, but there are microscopic puncta in the tissues The neoplasm is scattered throughout the section There is a good deal of hyperplasia of the endothelium More of the epithelium seems to comprise the bulk of the lesion than the blood vessels Perhaps that is why the lesion does not appear to be particularly red The patient has had this, I understand, for five years, which would point to the diagnosis of angioma rather than angiosarcoma A general pathologist from the sections might diagnose this as an angioendothelioma proliferating into the surrounding tissue, but dermatologists know that there are other lesions, such as granuloma pyogenicum and dermatofibromas, which appear to be infiltrative and yet do not have the neoplastic property of a true malignant condition I should say that these are capillary angiomas rather than angiosarcomas

Pityriasis Rosea? Neurofibromatosis Presented by DR EVAN B HUME

DISCUSSION

DR EVAN B HUME Why is neurofibromatosis aggravated by pregnancy?

DR BERTRAM SHAFFER Many conditions either develop or become aggravated during pregnancy Cutaneous tags, various pigmentations, verruca senilis and von Recklinghausen's disease belong to this group of eruptions

DR SIGMUND S GREENBAUM I offer the diagnosis of a mixed type of anetoderma None of the lesions look like pityriasis rosea The larger lesions resemble Schweninger-Buzzi disease

DR REUBEN FRIEDMAN I agree with the diagnosis of pityriasis rosea and von Recklinghausen's disease Dr Cipollaro of New York is opposed to biopsies in frank cases of neurofibromatosis, stating that in 13 per cent of the cases sarcoma develops at the site of the biopsy

Lupus Erythematosus, Scleroderma (Sclerodactylia), Raynaud's Disease, Sarcoidosis (Boeck's?) Presented by DR LEWIS M JOHNSON, Lancaster, Pa

Keratoses of the Palms and Soles (Chronic) (Caused by Arsenic?), Pigmentation (Generalized) (Caused by Arsenic?), Dermatitis (Atopic) of the Hands, Forearms, Ankles and Popliteal Areas (Chronic), Cirrhosis (Portal) of the Liver (Chronic) (Cause Undetermined) Presented by DR LESLIE NICHOLAS and (by invitation) CAPTAIN A FRISKEL

Tuberculosis of the Skin. Presented by DR H A. LUSCOMB for DR FRANK C KNOWLES

T C a Negro woman aged 21 years, presents a generalized, lichenoid, umbilicated, papular eruption with condylomata lata on the external genitalia The patient was admitted to the clinic in January 1947, with a history of an eruption of two months' duration

The Wassermann and Kahn reactions of the blood were strongly positive A blood cell count and the results of urinalysis were normal The serum calcium was 11 2 Roentgenograms showed the chest, hands and feet normal The result of a tuberculin test performed on April 1 with purified protein derivative (first and second test dilutions) was negative

The diagnosis from biopsy was tuberculosis

Antisyphilitic treatment with oxophenarsine hydrochloride was begun on Jan 17, 1947 The condylomata disappeared, but the rest of the eruption remained the same after three months' treatment Calciferol (vitamin D_2) therapy, 100,000 units daily, was started on May 31 and continued to the present time The eruption on the face had disappeared in six weeks The rest of the eruption has slowly improved

DISCUSSION

DR D M SIDLICK Only the microscopic evidence is in favor of tuberculosis of the skin, and I do not believe that one can make a diagnosis merely on the basis of the histologic picture The clinical evidence favors syphilis, and this is a macular atrophy following secondary syphilis

DR FRED D WEIDMAN This might be a case of sarcoid in the form that occurs in the American Negro, which responds to vitamin D_2 therapy The sections suggest sarcoid, although there are many lymphocytes, there are no giant cells The patient is anergic, but the other lesions, such as the bone changes, appear not to be present The disease is, however, in an early stage, and I think that the case should be watched because it may be one of sarcoid of the American Negro, which Dr Michelson thinks might be different from sarcoid of Boeck

DR C C THOMAS I have seen at least three examples of what appeared to be papular secondary syphilis which on further examination and failure to respond to antisyphilitic therapy turned out to be sarcoid I suggest a lymph node biopsy

Purpura Annularis Telangiectodes (?) Improved Following Treatment with Rutin and Ascorbic Acid Presented by DR SIGMUND S GREENBAUM

Follow-Up Report Presented by DR J M SCHILDKRAUT, Trenton, Pa

Some time ago I reported an extensive case of plantar warts—one of the worst I had ever seen The boy had an extensive case of fused warts on the whole anterior part of the foot and scattered warts on the heel and toes, he also had warts on his hands He had received roentgen rays, bismuth preparations and other medicaments without effect I gave him a course of bismuth injections and advised that he soak his foot, at the suggestion of Dr Livingood, in 3 per cent formaldehyde, and the condition cleared up

Reuben Friedman, M D, *Chairman*

Douglass A Decker, M D, *Secretary*

Oct 17, 1947

A Case for Diagnosis (Psychosomatic Dermatitis? Dermatitis Herpetiformis?) Presented by DR REUBEN FRIEDMAN and (by invitation) DR CONRAD STRITZLER and DR JOHN B ROXBY JR

Xanthoma Eruptivum Secondary to Lipid Nephrosis Presented by DR REUBEN FRIEDMAN and (by invitation) DR WALDO E NELSON, DR CONRAD STRITZLER and DR JOHN B ROXBY JR

Combined Simple and Cavernous Angioma Presented by DR MEYER L NIEDELMAN

D A, a white girl aged 2 months, presents over the entire left side of the face an angioma cavernosum It is bright red, and the prominence of the swelling lies over the parotid gland There are numerous both raised and flat simple hemangiomas scattered over the right side of the face and neck On the lower lip there is a similar lesion

A small red area developed in front of the left ear at 2 weeks of age Another lesion formed on the lower lip, then gradually new areas developed over the left and right sides of the face and neck The patient was seen two days ago, and arrangements are being made to treat the lesions with radium

DISCUSSION

CAPT R L GILMAN, U S N This patient should be treated with sclerosing injections or solid carbon dioxide I would not use radium or roentgen rays

DR MEYER L NIEDELMAN I am afraid to use sclerosing solutions about the scalp and face because of possible thrombosis of a cerebral vessel At a meeting of the American Academy of Dermatology and Syphilology a few years ago a case was reported in which death of an infant was due to the injection of a sclerosing solution for an angioma of the face I believe the cosmetic result would be poor with solid carbon dioxide, and this substance is ineffective in the cavernous type I shall use radium, and I am sure a regression of the angioma will take place

DR H E TWINING The more rapid the growth, the greater the response one gets from radium or roentgen rays

DR M H SAMITZ I suggest that a roentgenogram be taken of the face to see whether there is any involvement of bone

DR THOMAS BUTTERWORTH, Reading, Pa Frequently extensive hemangiomas occurring in the trigeminal area are accompanied with hemangiomas of the cerebral cortex, and in treating them with roentgen rays one exposes oneself to a medicolegal proceeding If cerebral lesions develop later, the patient's parents may ascribe them to the treatment given earlier At the age of 12 or 14 the angioma on the cortex of the brain may become calcified and can be demonstrated by roentgenogram

DR HERMAN BEERMAN What is "simple" angioma?

DR MEYER L NIEDELMAN There are two types present in this infant the small, flat type, which is simple, and the elevated, doughy, vascular type, which is cavernous

DR J M SCHILDKRAUT Port wine stains are notorious for their failure to respond to roentgen rays But Dr Pfahler and I have recently had infants with such lesions that did respond and we are of the opinion that if radiation is used early these lesions may respond

Sarcoid Solitary Lesion on the Nose Presented by DR CARROLL S WRIGHT and DR E R GROSS

Acne and Comedos in an Infant 8 Weeks of Age Presented by DR. H H PERLMAN

Tuberculosis Verrucosa Cutis on the Neck. Presented by DR MEYER L NIEDELMAN

Reuben Friedman, M D, *Chairman*

Douglass A Decker, M D, *Secretary*

Nov 21, 1947

A Case for Diagnosis (Cutaneous Diphtheria?) Presented by DR LEWIS M JOHNSON (Lancaster, Pa)

A M B, a white woman aged 28, presents a healing ulcer in the right lower quadrant of the abdomen, early necrotizing lesions on the inner side of the left thigh of three days' duration and numerous depressed scars on the left wrist, on the left breast, in the left groin, on the left leg and on the left side of the abdomen She also has a tumor on the left lower part of the back

The present condition developed on Oct 12, 1946, with a "red spot" on the left wrist which formed a blister, turned black, ulcerated and healed, leaving a deep scar Since then other similar lesions have developed When the ulcers develop, she sometimes has painful joints, malaise, nausea and severe menstrual cramps

The serologic tests for syphilis were negative A complete blood count revealed 76 per cent hemoglobin, 3,620,000 erythrocytes, 7,200 leukocytes, 75 per cent polymorphonuclear leukocytes, 23 per cent lymphocytes, 1 per cent monocytes and 1 per cent eosinophils

The microscopic examination of the biopsy section revealed a focus of incomplete necrosis involving essentially the stratified squamous epithelium and its immediate underlying connective tissue This reaction was associated with an inflammatory cell infiltration consisting essentially of eosinophils, plasma cells, lymphocytes and a few polymorphonuclears (neutrophils) This infiltrate occurred chiefly about the blood vessels in the subepithelial areas In some areas the walls of the blood vessels showed a similar infiltration There was also a granulomatous reaction resembling a foreign body reaction Numerous foreign body giant cells appeared in these lesions, and in many instances they contained greenish crystals New blood vessel formation was a prominent feature and appeared to be demarcating the area of necrosis The diagnosis was necrosis of the skin

DISCUSSION

DR CLARENCE S LIVINGOOD This could be cutaneous diphtheria. It might be a factitial eruption caused by an escharotic chemical, such as phenol or saponated cresol solution, but from a clinical standpoint the most likely diagnosis

is cutaneous diphtheria The patient has numbness and tingling of her hands and some weakness She had a severe sore throat about two months after the first lesion developed I suggest careful bacteriologic studies on the most recent lesion, done with the full realization that it is difficult to isolate the Klebs-Loeffler bacillus from the skin even when it is present A spinal fluid examination should be done, and if the patient has an elevated spinal fluid protein, it would lend weight to the thought that the numbness and tingling of the hands represent a neurologic complication of the cutaneous diphtheria

DR DONALD M PILLSBURY I saw this patient after Dr Livingood did, and our initial joint reaction was that culture for corynebacterium diphtheriae was indicated The usual sharp borders of a factitial eruption produced by an escharotic are also characteristic of many diphtheritic ulcers of the skin, and the differentiation may be difficult I suggest, in addition, very careful clinical study from the standpoint of peripheral neuritis or other late changes due to diphtheria toxin If any further collateral evidence of diphtheria is uncovered and if a factitial origin can be ruled out, I suggest administration of diphtheria antitoxin, even if the cultures are negative As has been pointed out, recovery of the organism may be difficult in the hands of even the most experienced bacteriologist, especially when the lesion is old or when local treatment, such as applications of penicillin, has been given

Sulzberger-Garbe Disease (?) (Exudative Discoid and Lichenoid Dermatosis) Presented by DR LOUIS GOLDSTEIN and (by invitation) DR J FERNANDEZ

H K, a white man aged 43, presents papulomacular eruptions on the trunk and extremities which are retiform in character The papules are large, flat topped and reddish-yellow or darker, with mild scaling The patient has had attacks of this condition since 1930 He was hospitalized in April 1947 for an intensely pruritic dermatosis of several months' duration He was discharged much improved after three weeks of treatment Several days after discharge the dermatosis recurred, and he was again hospitalized for five weeks and was discharged much improved Several days later the condition recurred again, and it has remained until the present time

A urinalysis showed occasional leukocytes, epithelial cells and some mucus Complete blood counts revealed 3,890,000 to 4,060,000 erythrocytes, 10,000 to 14,000 leukocytes, 60 to 82 per cent polymorphonuclear leukocytes, 16 to 33 per cent lymphocytes, 1 to 2 per cent monocytes, and 8 to 15 per cent eosinophils The blood sugar was 99 mg per hundred cubic centimeters of blood The urea nitrogen was 13 5 mg The serologic tests for syphilis elicited negative reactions On April 21, 1947, Dr Weidman reported the biopsy specimen to show psoriasis

The patient has been treated with coal tar solution N F, boric acid, amobarbital sodium (sodium amytal®), tripelennamine hydrochloride (pyribenzamine hydrochloride®), protein hydrolysate, starch baths and bismuth sodium triglycollamate (bistrimate®), with improvement

DISCUSSION

DR CHARLES R REIN, New York (by invitation) I agree with the diagnosis

DR MAX JESSNER, New York (by invitation) This condition was unknown in Europe but I have seen many cases in New York I suggest that the patient be treated with arsenic or be sent to Arizona, where most of these eruptions clear up

DR STEPHEN T WHELAN What type of arsenic does Dr Jessner use?

DR MAX JESSNER, New York (by invitation) I inject a 1 per cent solution of arsenic trioxide with 2 per cent phenol, starting with 0 25 cc daily and increasing to 1 cc daily

DR CLARENCE S LIVINGOOD I have no better diagnosis to offer than Sulzberger-Garbe disease, but I always feel dissatisfied with that diagnosis This patient is similar to one of mine whose eruption cleared up, partly because of hospitalization and partly because of therapy of various types The most notable thing about his course was that there would be a flare-up following an infection of the upper respiratory tract or the injection of an autogenous vaccine in a very small dose

Mycosis Fungoides Presented by DRS CLARENCE S LIVINGOOD and (by invitation) J P SCULLY

W B, a white man aged 82, was first seen on Oct 7, 1947, with the chief complaint of "sore on the back" which had been present for four or five months The process was said to have begun as a "small pimple" between the scapulas which the patient attributed to an insect bite received at the seashore At the time of the first visit, the patient presented a firm, reddish, indurated lesion measuring 4 fingerbreadths in diameter, between the scapulas The center was slightly raised and purplish, but gave no evidence of breakdown of tissue or fluctuation During a subsequent period of two weeks' observation, some exudation and a suggestion of superficial breakdown of skin were evidenced Three weekly injections of 300,000 units of penicillin in oil and wax were without effect on the process

The general physical examination disclosed nothing significant except a palpable liver edge 2 fingerbreadths below the costal margin There was no splenomegaly and no generalized or localized adenopathy The patient complained only of slight itching

The results of urinalysis were normal The serologic tests for syphilis elicited negative reactions A complete blood count revealed 79 per cent hemoglobin, 3,950,000 erythrocytes, 7,750 leukocytes, 58 per cent neutrophils, 3 per cent eosinophils, 34 per cent lymphocytes and 5 per cent monocytes, the color index was 1 01

Biopsy was reported to indicate lymphoblastoma and probable mycosis fungoides (The punch biopsy wound healed promptly)

The patient was given 600 r of roentgen rays in doses of 100 r over a period of sixteen days Exudation ceased after the second treatment, the induration regressed and the lesions flattened within two weeks

DISCUSSION

DR FRED D WEIDMAN When I first looked at the lesion, I thought that it might be Bowen's disease that had been overtreated The sections show that there is a reticuloendothelial disease, but I cannot quite make myself think that it is mycosis fungoides The epidermal changes are not sufficiently hyperplastic I think that it would come closer to being Spiegler-Fendt sarcoid, even though clinically that diagnosis would not quite fit But there are many of these reticuloendothelial disturbances that cannot be forced into some particular niche or pigeonhole that dermatologists have made Just as in Hodgkin's disease, there are atypical cases, and I think that this is one of them I cannot go further than to say that it is an abnormality of the reticuloendothelial system perhaps closer to Spiegler-Fendt sarcoid than to anything else

DR. MAX JESSNER, New York (by invitation) It is impossible to make a histologic diagnosis in the early stage of mycosis fungoides, since there is nothing characteristic histologically at that time Dr John Garb is treating patients with mycosis fungoides with antimony potassium tartrate U S P, and the results have been astonishing The patients react promptly to the therapy

DR J P SCULLY (by invitation) The diagnosis was made by exclusion I could think of no other lymphoblastoma that would produce no other systemic manifestations without other evidence of disease and persist for six months

Extensive Pityriasis Lichenoides et Varioliformis Acuta (Mucha-Habermann) Presented by DR REUBEN FRIEDMAN and (by invitation) DR HERBERT KAPLAN and DR JOHN B ROXBY JR

DISCUSSION

DR DONALD M PILLSBURY This is an unusually extensive and good example of this disease Whenever I see a patient with this disease, I am amazed that it can be so confidently classified in the textbooks in the parapsoriasis group There are many features of it which suggest a subacute infection, or at least a local reaction to the products of some infection I should like to hear Dr Blank discuss whether or not any such cases have been studied from the standpoint of a virus origin, I do not recall any such reports

DR HARVEY BLANK (by invitation) As far as I know, this particular disease has not been investigated recently along those lines At the moment, one of the means of investigation of such a case is to put the vesicle material directly on the little screens to be used in the electron microscope, and it is now possible within a matter of hours to differentiate smallpox from chickenpox Dr Geoffrey W Rake, of the Squibb Institute, has worked this out in considerable detail and is interested in material from any questionable case

DR. REUBEN FRIEDMAN Fluid from several of the vesicles was inoculated into the scratched cornea of a rabbit, with a negative reaction

DR LOUIS GOLDSTEIN Did this patient have lesions in the oral cavity in the acute stage?

DR REUBEN FRIEDMAN No Three days ago papular hemorrhagic lesions developed on the roof of the mouth and pigmented petechial lesions on the palms and soles

Multiple Recurrences of Infectious Syphilis Over Nineteen Years, Granuloma Inguinale Presented by DR HERMAN BEERMAN and (by invitation) DR MORTIMER S FALK

P D, a white man aged 40, presents pinkish verrucous-appearing hypertrophic growth on the ventral surface of the coronal sulcus, negative for Treponema pallidum on dark field examination The patient had primary dark field-positive syphilis in February 1928 He was treated with arsenical and bismuth preparations Dark field examinations were made on several occasions—December 1930, November 1932, April 1934 and November 1938, all with positive results (This case was first reported by Pariser [*J A M A* **113** 1206 (Sept 23) 1939]) The original lesion, however, did not heal completely at any time Granuloma inguinale was suspected as early as 1934 and a few injections of antimony potassium tartrate were

Résumé of Clinical Course

Date	Number of Injections	Drug	Serologic Reaction	Progress Note
2/29/28	. .	....	Kolmer 44 Kahn positive	Dark field-positive penile lesion
2/29/28-12/29/28	7	Arsphenamine Bismuth arsphenamine sulfonate	Kolmer negative	Patient lost from observation
9/19/30-9/25/30	2	Neoarsphenamine	Kolmer negative	Dark field-positive penile lesions
2/12/32 2/26/32	3	Bismuth subsalicylate	Kolmer negative	No clinical relapse
11/21/32	9	Trisodium arsphenamine sulfonate	Kolmer negative	Indurated, ulcerative penile lesion swarming with spirochetes, lesion was at same site as original monorecidive
1/19/33	9	Trisodium arsphenamine sulfonate, bismuth subsalicylate	Kolmer negative	
6/15/33 12/8/33	. 10	Trisodium arsphenamine sulfonate		Glans penis inflamed, ulcerative lesion
	10	Bismuth subsalicylate		
4/17/34 3/20/36	20	Trisodium arsphenamine sulfonate	Kolmer 00	Lesion on left side of glans penis, dark field-positive for T pallidum
	26	Bismuth subsalicylate	Kolmer 44 on 5 tests, 10/11/35 to 1/16/36	
8/13/34	3	Antimony potassium tartrate	Negative (cerebrospinal fluid) 1/24/36	On 6/19/34 inoculations (rabbit) were reported positive for T pallidum, lesion did not respond to therapy, possibility of granuloma inguinale considered
2/7/35	8	Fuadin®	Kolmer 44	Dark field-positive perianal condyloma and multiple indurated purulent secreting penile ulcers, condyloma healed under treatment
11/1/38	8	Arsphenamine	..... .	
8/1/39	3	Bismuth subsalicylate	Kolmer 44	
11/7/38	.	.. .		Ducrey test positive, Frei test negative
1/28/42 2/9/42	3	Bismuth subsalicylate	Kolmer positive	Patient returned with granulomatous lesion on frenulum which he stated had been present since original visit (14 years), dark field-negative for T pallidum, smear revealed presence of Donovan bodies
	3	Antimony potassium tartrate		
2/47	60	Penicillin, 2,400,000 units	Negative	Dark field-positive primary syphilis (diagnosed and treated in another institution)
10/2/47	.		Kolmer negative Kline negative	Patient returns with verrucous-appearing hypertrophic growth on ventral surface of coronal sulcus, dark field-negative for T pallidum
10/3/47	. . .			Biopsy granuloma inguinale

given In February 1947, dark field-positive primary syphilis was diagnosed at another institution, and the patient was given 2,400,000 units of penicillin According to the patient, the lesion did not heal

DISCUSSION

DR DONALD M PILLSBURY I did the original dark field examination on this patient in February 1928 As the history indicates, for many years thereafter, in spite of what was presumed to be good antisyphilitic treatment, lesions of early syphilis, from which T pallidum was recovered, continued to develop on his skin The patient apparently now has granuloma inguinale, but I would not doubt the capacity for infectious lesions of early syphilis to develop even now, in view of the past history A picture which I cannot get out of my mind in connection with this patient is that of rows on rows of filing cases in the Department of Medicine and Surgery of the Veterans Administration, all containing the records of men treated for syphilis in the Armed Forces Many of these have received penicillin therapy and, in the year 1945 at least, penicillin of very doubtful antisyphilitic potency When one observes relapses and/or reinfections after penicillin therapy and patients such as this one, the enormous potentialities of such patients in terms of the public health are very apparent Syphilis is far from being well controlled, and our methods to this end are still not so effective as they should be

DR DOUGLASS A DECKER, Allentown, Pa This is the first time that I have seen a white patient with granuloma inguinale

DR HERMAN BEERMAN I have seen this patient for nineteen years I can concur in the statement that he had a positive dark field examination in 1928 and that we obtained positive inoculation in rabbits with a portion of his penile lesion in 1934, even in 1934 we thought that he had granuloma inguinale, and he received some injections of antimony potassium tartrate then Every time that Dr Stokes wanted a dark field-positive lesion for teaching purposes he used to say "Get that boy" I think the primary diagnosis now is granuloma inguinale There were Donovan bodies present

FOLLOW-UP NOTE The patient was given 20 Gm of streptomycin intramuscularly in five days (Nov 25 to 30, 1947) The lesions healed promptly, without recurrence to date (October 1949)

A Case for Diagnosis (Senear-Usher Syndrome? Pemphigus Vulgaris?) Presented by DR CHARLOTTE JORDAN

DETROIT DERMATOLOGICAL SOCIETY

Henry A Brunsting, M D, *Chairman*

Hermann Pinkus, M D, *Recorder*

March 26, 1947

Necrobiosis Lipoidica Presented by DR H J PARKHURST, Toledo, Ohio

K D R, a married woman aged 39, presents on the inner aspect of the lower right shin a large coin-sized morphea-like patch of four years' duration, with sharp borders and some scaling of the surface The ivory-colored center shows telangiectases, and toward the border the tint was violaceous On the dorsum

of the left foot is a cluster of pea-sized brownish erythematous nodules grouped in a circle the size of a large coin These appeared after she had returned from Florida a week ago

Urinalysis and blood sugar studies showed no diabetes, and there was no family history of that disease

DISCUSSION

DR HARTHER KEIM The recent lesion on the left foot and the older one on the right foot look like granuloma annulare I wonder whether the large lesion on the shin is not the same

DR LOREN SHAFFER I agree with Dr Keim that this is a granulomatous process The older lesion is hardly typical of necrobiosis, because of the elevated border The youngest lesion has developed so quickly that it may be erythema diutinum Biopsy is indicated

DR ARTHUR JAMES The margin of the large lesion resembles granuloma annulare, the center looks like necrobiosis lipoidica

DR FELIX PINKUS The lesion looks like granuloma annulare, but everything on the legs below the knees is suggestive of necrobiosis

DR HARTHER KEIM We should keep in mind the case of Dr Belote's in which the disease later turned out to be ulcerating tuberculosis

DR HENRY BRUNSTING One must consider lipid disturbances of other types

DR HOWARD PARKHURST I am sorry that no biopsy could be done The lesion looked more typical when I saw the patient first, several months ago, and this is only the second time I have seen her The appearance of the patch has changed, possibly owing to the roentgen treatment she has received The lesions on the left foot are different, possibly due to insect bites, because she was in Florida, a week ago, when they suddenly appeared

Lupus Erythematosus Limited to the Lips and Buccal Mucosa in a Woman Aged 37, Duration Nine Years Presented by DR H J PARKHURST

Lupus Erythematosus of Mucous Membrane of the Lips and Buccal Mucosa in a Man Aged 37, Duration Eleven Years Presented by DR HENRY A BRUNSTING

Discoid Lupus Erythematosus of the Nose in a Woman Aged 41, Duration Fourteen Years Presented by DR HENRY A BRUNSTING

Two Cases of Congenital Ectodermal Defect (Incomplete) Presented by DR H J PARKHURST

Circumscribed Scleroderma Presented by DR ARTHUR JAMES

Circumscribed Scleroderma of Six Weeks' Duration (Scleredema?) Presented by DR ARTHUR JAMES

Multiple Idiopathic Hemorrhagic Sarcoma of Kaposi Presented by DR HENRY A BRUNSTING

J H, a Negro aged 61, first noticed small tumors on the soles of both feet about 1940 These have progressed to involve the entire right sole and toe and the left instep

Examination disclosed numerous pea-sized and larger round, firm nodules, pink to brownish, distributed over the soles and toes of both feet Some of the lesions, of a verrucous nature, have dropped out, leaving a pea-sized excavation

Results of laboratory examinations, including a complete blood cell count, differential count, urinalysis, serologic test for syphilis and roentgenogram of the chest, were all within normal limits A roentgenogram of the feet showed some disuse atrophy but no bone destruction A culture from the lesions of the feet disclosed gram-positive diplococci but no fungi Histologic examination disclosed a sarcomatous stage of multiple hemorrhagic pigmented sarcoma (Kaposi)

In addition to topical therapy, the patient received potassium iodide orally, and between Feb 11 and 19, 1947, he received seven roentgen treatments to the lateral surfaces of each foot (200 kilovolts, 50 cm distance, 4 mm of copper filter) for a total of 1,050 r to each area There was considerable improvement following radiation therapy

DISCUSSION

DR ARTHUR JAMES I saw this man seven years ago His feet were swollen and had draining sinuses Biopsy showed blastomycosis He improved very much with potassium iodide therapy

DR FELIX PINKUS Today I made a clinical diagnosis of Kaposi sarcoma, and the histologic picture seems to confirm this

DR HOWARD PARKHURST The lesions now look like the idiopathic sarcoma of Kaposi, but eight months ago the condition resembled mycetoma The sinuses which were present then cleared up with moist packs of potassium permanganate solution More recently, after roentgen treatment, the nodules have subsided

DR THOMAS MILLER I agree with the diagnosis of Kaposi sarcoma The most plausible explanation would seem to be that it has recently developed on the background of an older, infectious process

DR HENRY A BRUNSTING I believe that the clinical and histologic picture is consistent with the diagnosis of Kaposi sarcoma There has been considerable improvement in the clinical picture in the month since radiation therapy was administered

Porokeratosis (Mibelli) of the Thumb of a 7 Year Old Girl Presented by DR H J PARKHURST and DR HENRY A BRUNSTING

Bright Red Nodular Tertiary Syphilid on the Thigh, Duration Eight Years Presented by DR HENRY A BRUNSTING

News and Comment

GENERAL NEWS

Third Annual Clinical Session of the American Medical Association — The Third Annual Clinical Session of the American Medical Association will be held in Washington, D C, December 6 to 9

The Clinical Session will provide a full scale scientific program specifically designed for the general practitioner Outstanding physicians will discuss such subjects as diabetes, pediatrics, laboratory diagnosis, physical medicine and rehabilitation, arthritis, dermatology, diagnosis by means of the roentgen rays, cancer and poliomyelitis Coordinated with this outstanding scientific program will be approximately one hundred scientific exhibits which will present original work on the subjects discussed

The newest offerings of one hundred and twenty-five manufacturing firms will comprise the Technical Exhibition Here will be found the latest developments in scientific medical research, drugs and equipment

Televised surgical and clinical procedures, similar to those shown in color at the Annual Session of the American Medical Association in Atlantic City last June, will be presented at the Washington meeting The demonstrations will originate in the Johns Hopkins Hospital and will be shown on screens in the Armory The television schedule will be spread over four days

The House of Delegates will meet at the Hotel Statler during this session One of the first orders of business will be the annual selection of the general practitioner who has made an exceptional contribution of service to his community

An entertainment program for attending physicians and their wives is planned The highlight of this program will occur on Wednesday evening, December 7, when Philip Morris will originate its "This Is Your Life" broadcast from the Hotel Statler The radio program will be followed by a stage show, in which outstanding stars will participate

Blanks for hotel reservations and advance registrations may be found in *The Journal of the American Medical Association*

Book Reviews

Malattie cutanee e veneree ed alterazioni oculari By G Sala and P Noto, with prefaces by A Grosti and B Alajmo Pp 410 Palermo, Italy S F Flaccovio, 1948

This book, which is probably the most comprehensive monograph on the subject, is the combined work of the ophthalmologist, G Sala, and the dermatologist, P Noto, both of the University of Palermo, Italy The authors discuss, in parallel articles, the embryology of the skin and of the eye and all dermatoses and venereal diseases which may affect the eye and the lids The book contains a vast amount of factual, mostly clinical and often original, material in connection with a rather large bibliography

There are some shortcomings which should be corrected in a new edition There are no illustrations and no alphabetic index, and the paper is poor, probably because of postwar difficulties It would be to the advantage of the book if the authors would agree on more rigid editing It seems out of proportion to write a page or more on the dermatologic aspects of lichen planus and other dermatoses and then to mention, in a few lines, the rarity of participation of the eyelids The spelling of foreign names and titles of publications, especially in the German references, is poor Of greater importance than errors of this kind is the omission of discussion of the work of Brunsting and Sheard and others on the high threshold level of dark adaptation in pityriasis rubra pilaris However, these shortcomings should not distract from the great value of the work as a modern reference book

Of interest is the observation of the relative frequency of dermatogenous cataract in cases of generalized psoriasis In this connection, it may be mentioned that the authors estimate that cataract develops in 10 per cent of the patients with neurodermatitis (atopic dermatitis) This percentage appears to be a higher one than is observed in America, and the discussion should prompt a study of the eye in a large number of American cases

An Introduction to Dermatology By J H Percival, M D Eleventh edition Price, $9 Pp 349 Baltimore Williams and Wilkins Company, 1947

In general this is an excellent, small, yet complete book, in which the author well meets the difficult problem of attempting to cover a large and complex field briefly The material is well organized and clearly presented and indicates logical thinking throughout There are sufficient good colored illustrations to help the presentation greatly

Though brevity and a superficial approach are necessary in a book of this type, there seems to be an insufficient attempt made to link dermatology to the whole of medicine Mention of the more serious general involvement of the body of many dermatoses is omitted in the discussion of some conditions and but briefly touched on in others

American readers, although likely agreeing in general with the material presented, will undoubtedly have varying opinions regarding certain specific ideas expressed Among such controversial points, the following ones might be mentioned that the Senear-Usher syndrome is a type of generalized lupus erythematosus and that this syndrome is identical with pemphigus foliaceus, that dermatitis herpetiformis "may imperceptibly change its character to that of pemphigus," that twelve hours is sufficient time for patch testing and that "if there is no reaction, any suspicion of the substance used for the test may be dismissed"

Cosmetic Repair (Surgical) of Lupus Erythematosus Hypertrophicus et Profundus. Presented by DR SAMUEL M PECK

E B, a housewife aged 40, is presented from Mount Sinai Hospital, New York, with an eruption which appeared after exposure to sun and which has been present since 1925 The patient has been under observation since 1926 She has received a great deal of therapy, including treatment with gold and bismuth preparations, cobra venom and other remedies, but finally improved with administration of suramin sodium (naphuride sodium®) Subcutaneous infiltrations appeared in 1938 With improvement, the infiltrations disappeared, leaving atrophic areas resulting in cosmetic defects

There are still a few areas of activity on the face and scalp consisting of circumscribed patches of atrophy and telangiectasia The sites of the defects have been filled in by means of skin grafts

The patient has been kept practically free of lesions by injections of naphuride® The dosage was 100 mg with increase at each injection until a maximum dosage of 300 mg was given All injections were intramuscular and given once a week From October 1945 until the present she has received several courses of this drug the first consisting of eleven injections and the second of eight The third course, which comprised seven injections, was begun in June 1946

The reason for presenting the case was the great loss of subcutaneous fat at the sites of the previous infiltrations, with scarring over the flush areas of the cheeks A repair, consisting of dermal grafts, was performed by Dr Michael L Lewin Only the dermal component of the graft was utilized in order to limit shrinkage as much as possible

DISCUSSION

DR FRANCIS P MCCARTHY, Boston May I ask Dr Peck whether, on the basis of its use in 40 cases, he feels that this drug is safe for use by the medical profession? It seems to me that it is a toxic drug, capable of producing a renal irritation, as evidenced by casts and albuminuria Personally, I would prefer to use a less dangerous remedy

DR MAURICE J COSTELLO I have used naphuride® in the treatment of lupus erythematosus in 6 cases, with spectacularly good results in 3 of them, in half of the patients severe toxic reactions developed and the use of the drug had to be discontinued One patient had disturbance of vision, 2 had swelling of the hands and feet accompanied with intense pruritus, others had pain and swelling of the

joints and in 1 the urine indicated renal irritation I believe that the drug is to be used with great caution It is effective, but it should be given only in the refractory, severe cases

DR. GEORGE C ANDREWS I agree with Dr Costello I think Dr Peck has had more experience with germanin in the treatment of lupus erythematosus than anybody in this city, and he can do things with it, perhaps, that the average physician cannot do I agree fully with his remarks, except that I think he should be a little more careful in explaining how toxic naphuride® is Severe anemia, hepatitis and nephritis occur from its use The total dose must be kept under 1 Gm for a long period I feel, as Dr Costello does, that it is an extremely toxic drug I no longer use it in cases of pemphigus, although I do use it for lupus erythematosus of the discoid type in small doses of 100 mg once a week for six or eight weeks If the patient is carefully watched, such doses are fairly safe In some cases fine results are obtained, and in others it does no good

A Case for Diagnosis (Lymphoblastoma? Pemphigus? Dermatitis Herpetiformis?) Presented by DR. ISADORE ROSEN

E A, a woman aged 70, had an eruption of four years' duration This began as vesicular plaques on the wrists and hands After roentgen ray treatment the eruption disappeared, but it soon recurred on the face, chest and extremities Since then there have been complete remissions and also exacerbations of varying degree, the patient having to be hospitalized on several occasions

The eruption during the past few years has been generalized and has consisted of grouped and fused lesions of vesicular character On the face and extremities infiltration has been frequently observed, and at times the lesions have been oozing or covered with scales At other times they have been annular, with central vesicular crusting, and have closely resembled pityriasis rosea In August 1946, shortly before her hospitalization, almost the entire surface of the skin was involved, except for the palms and soles At that time the patient presented on the face, neck and chest diffuse dull erythema, edema and exfoliation The rest of the body showed rounded erythematous lesions from 2 to 7 cm in diameter, with a scaly collar just inside the erythematous border In some areas there were flattened bullae containing clear fluid During the patient's stay in the hospital new bullae appeared from time to time

The Wassermann and Kahn reactions of the blood were negative Frequent blood counts showed leukocytosis, with a count which at times reached a figure of about 18,000, and a high eosinophil count, on some occasions as much as 27 per cent Roentgenograms of the lungs revealed moderate central thickening of the lymphomatous type, with clear peripheral lung fields A roentgenogram of the spine showed localized hypertrophic changes of the lower cervical area.

Patch tests with 30 per cent potassium iodide and potassium bromide ointment gave a strongly positive reaction Chemical studies of the blood, including determination of the nonprotein nitrogen, total protein, albumin, globulin, icterus index, calcium, inorganic phosphate and sugar, showed normal figures The last examination of the erythrocyte sedimentation rate during an exacerbation showed 93 mm per hour The basal metabolic rate was within normal limits

Four biopsies taken at different times were reported to show (1) chronic dermatitis, (2) neurodermatitic reaction, (3) psoriasiform dermatitis, and (4) pemphigus The description of the last slide was as follows "There is an

DR WILBERT SACHS This patient has had long-standing dermatosis, and a superimposed pemphigus developed I believe that the underlying dermatosis is a distinct dermatologic entity that has never before been described I have now seen about 6 such cases, and the microscopic picture is always the same There is a neurodermatitic reaction, with a focal cellular infiltration of plasma cells The process suggests an exudative discoid and lichenoid dermatosis on the one hand and a mycosis fungoides on the other Yet it is neither of these diseases but a definite entity falling somewhere between both Clinically these patients may have macules, papules, nodules or patches This patient also has pemphigus, probably due to a toxic reaction

DR WALTER F LEVER, Boston The cutaneous lesions are eczematous in nature It is possible that the disease will turn out to be mycosis fungoides Frequently in the prefungoid state of mycosis fungoides it is impossible to find in the histologic sections atypical cells which would establish the diagnosis of mycosis fungoides Instead, only banal inflammatory changes are present In regard to a diagnosis of pemphigus, I think that is a disease entity and does not develop as a toxic reaction secondary to another dermatosis I would not dare to make a diagnosis of pemphigus on histologic grounds alone, except in some cases of pemphigus vegetans Bullae may occur as an unspecific reaction, both in eczematous cutaneous disorders and in mycosis fungoides

DR WILBERT SACHS I did not intend to imply that this was a case of mycosis fungoides In fact, I believe that disease will never develop in the patient This is not the proper time to discuss the differentiation between dermatitis herpetiformis and pemphigus I am not convinced that we know what pemphigus is, to me, the lesions of that disease are toxic bullous manifestations There are certain characteristics on which a diagnosis of pemphigus can be made microscopically

DR GERALD F MACHACEK We have had similar problems at the Presbyterian Hospital in which the diagnosis was uncertain The lesions were pemphigoid or were thought to be those of Duhring's disease, and treatment with sulfapyridine was tried and found wanting One such case was presented before the New York Academy of Medicine last Tuesday Dr Vero found that the lesions in that case and in another disappeared with large doses of vitamin A Perhaps Dr Rosen has already tried that form of therapy

DR ISADORE ROSEN This patient has been under observation for more than four years The only subjective symptom has been intense itching, and her general physical condition has never been impaired I am of the opinion that this bullous eruption is probably due to the effects of treatment over many months

Poikiloderma Vasculare Atrophicans with the Histologic Picture of Mycosis Fungoides Presented by DR DAVID BLOOM

Dermatitis Factitia Dystrophy of the Nails and Keloids of the Palms and Soles Presented by DR GEORGE C ANDREWS

H C F, a widow aged 66 from the Roosevelt Hospital, has arteriosclerotic heart disease, diverticulosis of the colon and hypertrophic arthritis Her psychiatric status has not yet been determined

In 1935 the patient was told that she had a fungus infection of the finger nails, which she felt was the reason for her various functional and organic disturbances Since that time she has scraped her palms, soles and finger nails daily in order to "rid her system of disease"

There is almost complete absence of the finger nails and toe nails On the palms and soles are deep, red, linear, thickened areas On the hands, these extend over the palmar surfaces of the fingers

The Kline and Mazzini reactions of the blood are negative The urine is normal, and a complete blood count shows a moderate hypochromic anemia The basal metabolic rate is —4 per cent

Moniliasis Presented by Dr George C Andrews

R V, a girl aged 9, is presented from the Vanderbilt Clinic She was normal and healthy at birth and was well until the age of 2, when "double pneumonia" developed After this she remained underweight and had recurrent furunculosis which continued until the onset of the present illness In August 1943, when the patient was first seen, there was an eruption involving the scalp, mouth, nails and skin which had appeared ten months previously The patient had been hospitalized elsewhere, without improvement

On admission in 1943 the child appeared malnourished Purulent crusted lesions were present on the scalp The mucous membranes were covered with a grayish exudate, the nails were thickened, and many poorly limited, scaling, erythematous lesions were present on the shoulders

Extensive studies have been carried out in the three and one-half year period, only the pertinent findings are presented Repeated cultures of material from the scalp, skin, nails, mouth, sputum and feces were positive for Candida albicans Roentgenograms of the gastrointestinal tract in 1945 showed disturbed function of the ileum In 1946, agglutination of the blood serum for C albicans was positive in a dilution of 1 128

Examination of tissue from the back revealed intraepidermal pustules, with a leukocytic infiltrate in the pars papillaris of the corium

Locally, various preparations, including sulfur, sodium perborate, sodium propionate and gentian violet, have been used Crude liver extract multiple vitamin preparations, Candida vaccine and antiserum were used systemically In 1945, during a nine week period of hospitalization, a protoanemonin antibiotic was administered locally and orally Since July 1946 treatment has included iodine solution locally and strong solution of iodine with folic acid by mouth Recently there has been slight improvement in the cutaneous lesions, although the scalp, mucous membranes and nails are unchanged

DISCUSSION

Dr George C Andrews I have always believed in the use of iodine for moniliasis, and this case is presented to show the effect of that drug The patient has been helped a good deal She has also been getting folic acid by mouth during the past few weeks In the *British Journal of Dermatology* there have been reported cases of tropical sprue cured with folic acid

Dr Maurice Sullivan, Baltimore I should like to suggest to Dr Andrews, in case the eruption does not respond to iodine, the use of sodium caprylate, which has been reported to cure moniliasis when other fungicides fail

DR J GARDNER HOPKINS I would question Dr Peck's comments regarding Candida albicans on normal skin, because some years ago Dr Rhoda Benham made careful surveys of normal skin and found other species of Candida but could not find C albicans I think if the differentiation is properly made, one may say that M albicans is rare or nonexistent on normal skin It is found in the normal intestine I should like to testify to the improvement of this patient under Dr Andrews' treatment We had her under our care for some time, using sodium caprylate among other things, and she was much worse than she is today

DR DUDLEY C SMITH, Charlottesville, Va In Washington a symposium on antibiotics was held recently There were reports on two substances with fungicidal properties both on local application and on internal injection One was obtained from Bacillus subtilis, although it is not the same as subtilin, and is called "eumycin" The other was developed in the Department of Agriculture last year in an attempt to find something to counteract "tomato wilt" They obtained an extract from tomato leaves which is called "tomatin" Both agents, so the reports stated, have a good therapeutic effect in vitro in various types of fungus infections—monilia, trichophyton and yeast

DR C GUY LANE, Boston It seems to me that the disease moniliasis is increasing We seem to have had more patients in our clinic recently, and I am just as much impressed with the obstinacy of the disease as I was years ago I do not believe we have made much headway in therapy We have had 3 or 4 cases lately in which there was opportunity to make fairly careful studies, and we have run the gamut of therapy We have been interested in trying the method developed at Duke University, where a person with pulmonary moniliasis recovered after serum therapy (J A M A **130** 205 [Jan 26] 1946) I wonder if anything further has been done, perhaps in the way of increasing the titer of rabbit serum by gradually increasing doses A great deal more intensive study is needed in these cases because they are potentially serious Lesions involving the mouth and larynx are obstinate and become generalized, with a fatal ending

DR JASPER L CALLAWAY, Durham, N C We also have our troubles treating moniliasis of the skin at Duke Hospital The patient whom Dr Lane mentioned had pulmonary moniliasis and was treated with a stepped-up course of antiserum and eventually recovered We have not been able to cure any patients with generalized moniliasis of the skin, regardless of the type of treatment

Sarcoidosis (Leprosy?) Presented by DR MAURICE J COSTELLO

A Case for Diagnosis (Periarteritis Nodosa? Eosinophilic Granuloma?) Presented by DR FRANK C COMBES

This case was previously presented before the Section of Dermatology and Syphilology of the New York Academy of Medicine on Jan 7, 1947

Actinomycosis Presented by DR FRANK C COMBES

M A, a girl aged 17, is presented from Bellevue Hospital with a lesion of the left side of the mandible She was previously presented by Dr Maurice J

Costello at the New York Dermatological Society in January 1947 and by Dr Emanuel Muskatblit at the Section of Dermatology and Syphilology of the New York Academy of Medicine on Feb 4, 1947

DISCUSSION

DR. GEORGE M LEWIS At a recent meeting in Cleveland, Lamb, of Oklahoma City, discussed the therapy of actinomycosis and stated that it should include (1)

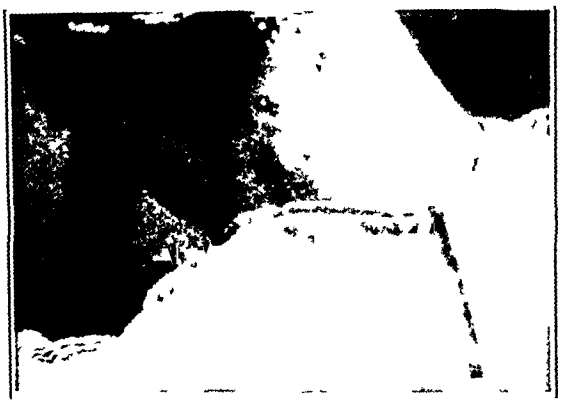

Fig 2—Periarteritis nodosa in a woman aged 35

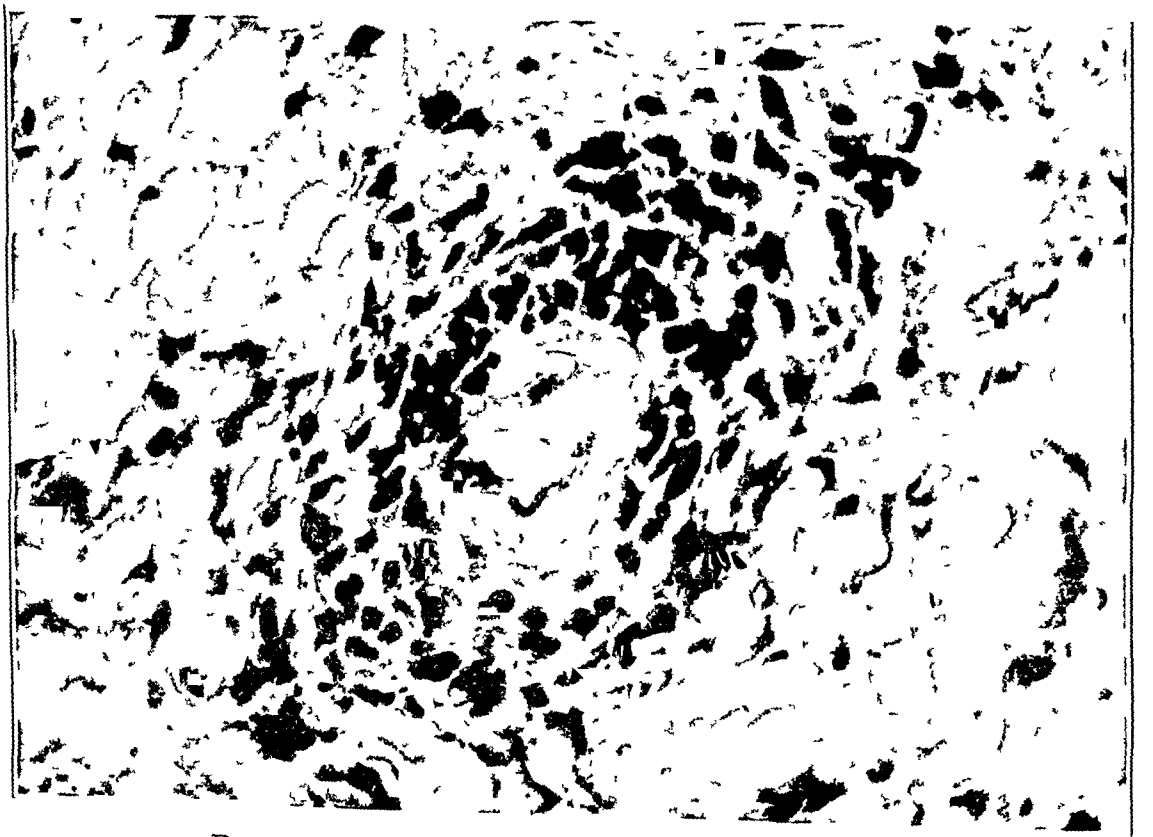

Fig 3—Photomicrograph of area of periarteritis nodosa

penicillin in large doses, which this patient has received, (2) one of the sulfonamide drugs, and (3) roentgen irradiation He favored this combination of remedies as superior to any one alone or to any other type of treatment now available

Dermatitis Factitia Actinomycosis? Presented by DR THOMAS N GRAHAM

Pachyonychia Congenita (Keratosis Palmaris et Plantaris Dystrophia Unguium and Leukoplakia Oris) Presented by DR FRED WISE

S H, a woman aged 40, and L H, her son aged 16, were previously presented before the Manhattan Dermatologic Society on January 14 by Dr Fred Wise

Both patients show hard, thick, painful, hyperkeratotic, lemon-colored growths on the soles, heels and toes The toe nails and finger nails are elongated, curved, discolored and dyskeratotic There are leukoplakic patches on the buccal mucosa

Fig 4—Dermatitis factitia in a woman of 38

and also on the tongue in the mother, who in addition presents dry, scaly, diffuse, seborrheic patches on the scalp Her basal metabolic rate was —20 per cent in February, and the son's was —14 per cent

DISCUSSION

DR FRED WISE This is the second case of the kind to be described in this country Cole and his collaborators described a case fully in the ARCHIVES, and this case is almost an exact replica of theirs The problem is one of therapy Both patients are practically crippled One lesion on the mother's knee was excised and a full thickness graft applied, and the growth recurred promptly in the area of the graft Dr Peck suggested administration of large doses of vitamin A, and this is being given, but too little time has passed to expect results I am pessimistic about any treatment whatever, except possibly an orthopedic procedure to permit the patient to walk with some degree of comfort

Fig 5—Hyperkeratotic growths of pachyonychia congenita in a boy aged 16

Fig 6—Dyskeratotic toe nails and finger nails in same boy as in figure 5

Incontinentia Pigmenti Presented by DR J GARDNER HOPKINS

J A M, a girl aged 5½ months from the Vanderbilt Clinic, was previously presented by Dr Helen O Curth before the Section of Dermatology and Syphilology of the New York Academy of Medicine on March 4, 1947

Most noticeable on the inner aspect of the thighs but visible also on the sides of the trunk are wavy parallel bands of hyperpigmentation in typical zebra pattern The skin is otherwise normal

DISCUSSION

DR FRED WEIDMAN, Philadelphia A number of years ago I performed an autopsy on an infant with peculiar transverse bands of pigment across the abdomen, but in paraffin sections I could not find the pigment which was to be expected Perhaps Dr Hopkins has had the same experience, because in his sections the pigment was inconspicuous However, in frozen sections, it was conspicuous indeed It is true that melanin pigment is not supposed to be dissolved in our histologic embedding agents, but perhaps in Dr Hopkin's case, too, frozen sections would show the pigment more plainly than do the histologic sections I reported my case under the name of "Transverse Hyperpigmented Lines of the Thorax and Abdomen of a Negro Infant" in the ARCHIVES (**37** 517-523 [Aug] 1919)

DR J GARDNER HOPKINS Was the pigment in the epidermis or in the chromatophores?

DR FRED WEIDMAN, Philadelphia In the epidermis

DR GERALD F MACHACEK This type of disorder has also been reported as familial chromatophore nevus by Naegeli and as melanodermatosis congenita by Siemans

DR J GARDNER HOPKINS I do not believe that this case is parallel to Dr Weidman's It corresponds to the cases described by Naegeli and by Bloch and Sulzberger in which pigment was in the chromatophores under the skin and not in the epidermis

A Case for Diagnosis (Behcet's Syndrome? Pemphigus? Leukemia Cutis?) Presented by DR EUGENE F TRAUB

A Case for Diagnosis (Lichen Planus and/or Lupus Erythematosus of Lips and Tongue Oriental Sore of Forearm) Presented by DR MAURICE J COSTELLO

G R, presented from Bellevue Hospital, was born in the United States and was taken to Greece when he was 14 years old, where he remained until about four months ago He was a guerilla fighter during the past two years in Greece. He does not smoke

About 15 months ago an erythematous patch appeared on the patient's right forearm, persisting until about three months ago, when it developed into an ulcer After biopsy was performed at this site the ulcer healed spontaneously A hyperpigmented scar can be seen

About four months ago a small superficial red area appeared on the left side of the dorsum of the tongue It increased in size to that of a 25 cent piece, became superficially eroded with a grayish pellicle-like border, and caused some pain when the patient was eating and drinking

During the past three weeks reticulated whitish streaks on the lower lip suggestive of lichen planus have developed A small superficial erosion has recently developed on the center of the tongue, medial to the one just described There has been no regional adenopathy

Dark field examinations of the lesions on the tongue and arm gave negative results, as did the Mazzini reaction of the blood A complete blood count, examination of the urine and roentgenograms of the lungs revealed no abnormalities

Biopsy of the lesion on the arm, done at Bellevue Hospital, showed a nonspecific granuloma with epithelioid cells, plasma cells and lymphocytes

Material from the lesion on the left side of the dorsum of the tongue was examined by Dr Fred D Weidman, who reported the lesion to be syphilis or oriental sore He found the epidermis to be enormously acanthotic and parakeratotic Although its squamous cells were greatly swollen, there was no evidence of neoplastic activity, even at the basement membrane There the basal cells had undergone metaplasia into squamous forms There, too, many of the inflammatory infiltrative cells of the corium were infiltrating the epidermis A rather heavy infiltration of inflammatory round cells lay immediately below the epidermis It crowded the papillae but did not extend farther than the subpapillary plexus of vessels The cells were distributed diffusely, and although lymphocytes were dominant, there was a large intermixture of elongated nuclei which were interpreted as epithelioids However, none of them was congregated into individual foci in such a way as to constitute miliary granulomas There were numerous other elongated nuclei which were clearly those of histiocytes, but they were readily distinguishable from the plumper epithelioid ones

The significant features in the diagnosis resided in the epithelioid cells Such cells do appear in the lesions of oriental sore, but in the absence of the specific organisms the epithelioids could reasonably be those of syphilis or tuberculosis, the diffuse distribution would point more toward syphilis The protozoa were not recognizable in these sections

DISCUSSION

Dr Fred Weidman, Philadelphia The solitary item of significance in the histologic picture is the presence of epithelioid cells, which are not gathered into foci to indicate definite miliary granulomas of either syphilis or tuberculosis In other words, it is a diffuse reaction such as occurs in pneumonia alba In such a situation it is necessary to resort to methods for the identification of the parasite itself I might say that the only time recently that I have seen the Leishman-Donovan body in sections was at Dr Lloyd W Ketron's laboratory, but that is unusual A much more preferable method of demonstrating the parasites is by means of smears, so I should say that if the pursuit of the Leishman-Donovan body is to be continued, that is the method of choice After seeing the patient today, I do not think the lesion could be that of leishmaniasis, as the infiltration of the tongue is not particularly heavy It is rather superficial for that disease, and leishmaniasis is usually more suppurative, as I recall it, there is no evidence of pus in the sections After seeing the patient again, I do not think it is likely to be syphilis, which I intimated in the histologic reports I was swayed by the fact that the infiltration is diffuse

Dr Clarence S Livingood, Philadelphia Several years ago I had an opportunity to observe a rather large number of patients with cutaneous leishmaniasis, and this case certainly does not correspond with any of those which I have seen I gathered that the type of ulcer which the patient had was not characteristic of that disease According to the information which I obtained from him, his stay abroad was entirely confined to Greece, and as far as I know leishmaniasis does not occur in that country

Dr Bernard Appel, Lynn, Mass The lesions on the lips and in the mouth are, in my opinion, consistent with lupus erythematosus It is not unusual, in my experience, to find lesions on the lips which in the early stages resemble those of

lichen planus clinically because of the white reticulation and their limitation to the vermillion of the lip With the progress of the disease, however, the lesions become more characteristic as they extend to the glabrous skin I anticipate that that is what will happen in this case Furthermore, I have not found that lichen planus produces such extensive and persistent ulceration of the tongue when it does occur there, that is to say, this picture is more consistent with lupus erythematosus If it actually is lupus erythematosus, it is also my opinion that it is likely to be extremely resistant to treatment and that the prognosis should be guarded

DR FRANCIS P MCCARTHY, Boston Dr Weidman, does the lesion on the tongue show epithelioid tissue?

DR FRED WEIDMAN, Philadelphia Yes

DR FRANCIS P MCCARTHY Do we get this reaction in lupus erythematosus?

DR FRED WEIDMAN No

DR MAURICE J COSTELLO The question of tuberculosis of the tongue also came up, but roentgenograms showed the chest to be normal We have seen patients who had both lichen planus and lupus erythematosus simultaneously I think the lesions on the lower lip suggest lichen planus and am inclined to agree that the lesion on the tongue is lupus erythematosus or lichen planus clinically

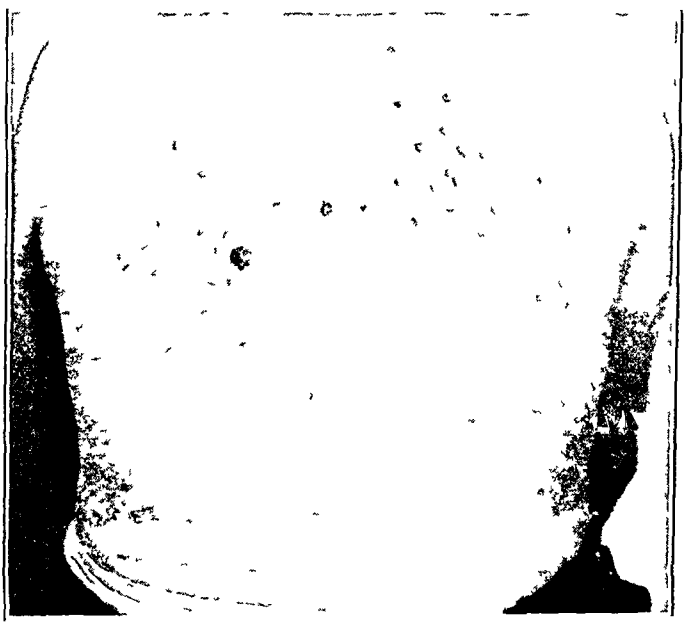

Fig 7—Lesions of leiomyoma

Leiomyoma Presented by DR ANTHONY C CIPOLLARO

P P, a man aged 52, is presented from the Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital, with an eruption of fifteen years' duration which has not changed essentially in the past twelve years

In the scapular region there is a symmetric eruption of slightly reddish, mostly oval, elongated and spherical infiltrated, firm, nodular lesions which are arranged in the lines of cleavage There is a moderate number of similar but smaller and less indurated lesions in the lower lumbar and gluteal region Some of the lesions are tender to pressure The patient complains of severe pain in the region of the eruption during cold weather

Fig 8—Photomicrograph showing leiomyomatous changes

Routine examination of the blood and urine gave normal results

Biopsy of a nodular lesion was reported previously to show neuroma Recently another biopsy was reported as showing leiomyoma

Unfiltered roentgen irradiation seems to have alleviated the pain of which the patient has complained

DISCUSSION

DR WILBERT SACHS I made both diagnoses I feel that in regard to multiple small lesions for which the diagnoses of both neuroma and leiomyoma are suggested it is possible that it is not a single, distinct type of tumor but a combination of both Of course it is often difficult to differentiate between neuroma and leiomyoma In this case we did some special stains on the first section and these showed a neuroma On the second section it was not necessary to do any special stains since there was a classic picture of leiomyoma

Pityriasis Rubra Pilaris Uninfluenced by Treatment with Vitamin A Presented by DR E W ABRAMOWITZ

Ragweed Dermatitis Presented by DR MAX SCHEER

P B, a man aged 65, is presented from the Skin and Cancer Unit of the New York Post-Graduate Medical School and Hospital He loads Pepsi-Cola bottles as an occupation He was in good health and free from any cutaneous disease until September 1936, when he walked through some lots in Astoria, N Y, without stockings A vesicular eruption appeared on the dorsa of the feet and legs which was at first called eruption from poison ivy and which lasted five months It recurred in September 1937, when it was slight on the feet and legs, mild on the face, hands and forearms and severe on the scrotum The eruption then became perennial, with exacerbations from September to May June and July are the most comfortable months for the patient

There is a thickened, lichenified eruption on the face and forearms The eruption stops rather abruptly on the upper third of his forehead, which is protected by his hat

Reactions to patch tests with oleoresins of short ragweed, cocklebur, sheep sorrel, Kentucky blue grass, red top, poison ivy, orchard grass and timothy were positive Patch tests with the protein extracts of trees, grasses and weeds showed a positive reaction only to oak Scratch tests with these protein extracts gave negative results

The histologic picture was that of a contact type of eczema

No specific treatment has been given as yet The patient has been receiving eight 50 mg tablets of tripelennamine hydrochloride (pyribenzamine®) daily, with only slight alleviation of the itching

DISCUSSION

DR JOSEPH MULLER, Worcester, Mass From the appearance I would be likely to believe that it is a ragweed dermatitis, but, on looking at the calendar and the patient, I just cannot accept that diagnosis After all, ragweed dermatitis is nothing else but a contact dermatitis, and the patient has certainly not been exposed to ragweed for a long time The fact that the reactions to patch tests were positive means nothing I think the patient has at some time had contact dermatitis If ragweed caused the trouble, it should have started in the fall and be over by now

DR JOSEPH GOODMAN, Framingham, Mass In cases of ragweed dermatitis, which lasts around the year, it must be remembered that there is often a cross sensitization between ragweed and Pyrethrum I note that other tests were done in this case, but I see no reference to Pyrethrum It would be possible for the patient to be exposed to Pyrethrum the year round That should be considered as a possibility

DR BERNARD APPEL, Lynn, Mass I should like to confirm the observations made by the last speaker and also to point out the fact that many patients subject to ragweed dermatitis are those who live in the country and work around barns where sprays against flies and insects are used, and of course we know that they contain Pyrethrum and products of that family In my opinion it is important to do patch testing with these substances, as well as with the solvents used in insecticides

DR DONALD S MITCHELL, Montreal This man has never been hospitalized I wonder whether it would help to admit him and remove ordinary contacts such as clothing and soaps

DR JACK WOLF The eruption on the torso as seen today is incidental, it developed after a recent cold and may be the result of medication which he received It has no relation to the other eruption This man has been tested with other oleoresins as well as ragweed fractions We have had a number of cases of ragweed dermatitis in which persistent eruptions developed and remained throughout the entire year after several seasonal attacks This persistence may be due to the development of sensitization to other allergens which act at the same site

Lymphoblastoma Mycosis Fungoides with Eczematous Lichenoid and Granulomatous Lesions Presented by DR A BENSON CANNON

March 17, 1947

Mycosis Fungoides in a Patient with Psoriasis Presented by Dr L M Waterhouse

J J, a man aged 46, born in the United States, first consulted me twelve years ago, at which time a diagnosis of psoriasis was made Six or seven years ago he was treated at a well known New York dermatologic clinic where the diagnosis was confirmed clinically and histologically He had received ultraviolet rays, coal tar preparations and other topical medication There was no history of his ever having received arsenic preparations Two years ago the lesions became raised and tumor like At that time a biopsy specimen from one of these lesions was reported as suggesting lymphoblastoma, but no more definite diagnosis was made The biopsy was repeated two months ago by another histopathologist, who suggested the possible diagnosis of mycosis fungoides

Results of repeated serologic tests for syphilis were negative Results of blood cell counts and urinalyses were normal

Examination shows a generalized eruption There are quarter-sized to dollar-sized flat, red, scaly patches There are a few lesions on the lower part of the back and thighs, which are raised and tumor like The face shows an ill defined erythema with scaling On the scalp are similar patches with alopecia

DISCUSSION

Dr Seymour H Silvers This is a most unusual case It seems that the diagnosis of psoriasis was established independently by different competent dermatologists This diagnosis was corroborated by histologic studies At present there are seen a sufficient number of lesions which are infiltrated and tumor-like to warrant a clinical diagnosis of granuloma fungoides However, we cannot completely ignore the findings of two able histopathologists who failed to corroborate the diagnosis of granuloma fungoides It is not unusual for the histopathologist to fail the clinician when the latter needs him most

Dr L M Fruchtbaum The picture is not that of psoriasis On the other hand, there are two large lesions and numerous smaller ones on the body and extremities which are definitely infiltrated In spite of the fact that the patient feels and looks physically well, I believe that this is a case of mycosis fungoides

Dr E A Gauvain I believe that the disease in this case was originally mycosis fungoides, as it is now I did not see any lesions typical of psoriasis on this patient, although such a diagnosis might have been considered in a few lesions had they been the only ones present I have never seen a case of undisputed psoriasis, even though followed through many recurrences, that terminated as mycosis fungoides Clinically there is now a polymorphous type of lesion, changing in character, of a dusky color, causing some itching and finally developing into nodules, which, to my mind, are typically mycosis fungoides

Dr Abraham Walzer Clinically, this is a case of mycosis fungoides The disease developed in a manner that it does in many cases It never was psoriasis, irrespective of the fact that histologically it was first reported as psoriasis

Mycosis fungoides may begin with what may appear to be psoriasis, parapsoriasis, eczema or any other condition I believe that just as the clinical picture, at the start, may be atypical, so the histologic picture may be more or less vague and indefinite At the present, this man shows lesions which, to my mind, are classic examples of mycosis fungoides

Epithelioma of Penis Presented by DR S I GREENBERG

Multiple Keloids Presented by DR MAX LERNER

J G, a girl aged 12, was seen at the Kings County Hospital Dermatologic Clinic on March 3, 1947 She had chickenpox in October 1946, and "marks" developed where there had been blisters

There are hard nodules, pea to bean size, distributed on the face, neck, abdomen and thighs Some are colorless and others yellowish white A few are erythematous with telangiectasia All the lesions are limited to the sites of the original varicella blisters There is no history of keloidal scars from previous injuries

DISCUSSION

DR ABRAHAM WALZER The keloid tendency does not have to be present during the entire life of the patient There may be periods when the tendency does not show itself My experience has been that if keloid is treated before it has been present six months, with roentgen rays, there is a chance of flattening of the lesion After six months, roentgen therapy is of no value This has been explained on the principle that connective tissue cells mature in about six months When the cell becomes fully mature, it cannot be reduced, but as it is growing and developing (that is, up to six months), its growth can be stopped No matter how much roentgen therapy is given after six months, it is of no value However, if the lesion is excised and roentgen rays given, the lesion may be suppressed

Generalized Sarcoidosis Presented by DR MAX LERNER and DR FRANK D JENNINGS JR (by invitation)

Seymour H Silvers, M D, *Secretary*

April 21, 1947

Xanthoma Tuberosum Presented by DR C T CHIARAMONTE

Xanthomatosis Juvenilis Presented by DR C T CHIARAMONTE

V S, a white girl, aged 5 years, has several discrete, bean-sized, yellowish nodules on the face and neck Her liver is enlarged to 2 fingerbreadths below the costal margin with an even, smooth edge

This child was first seen when she was 6 weeks old She showed many shiny, yellowish nodules which were generalized and of varying sizes There was a reddish halo around the lesions Some of the larger ones were oval in shape Many of the lesions showed multiple punctate depressions at the follicular orifices Lesions were also found on the mucous membranes of the mouth The lesions were noticed soon after birth

The infant was placed on a low fat diet and was reexamined a year later It was observed that occasionally there was a generalized flushing of the skin During the period of observation, some of the lesions appeared vesicular, the mouth lesions disappeared and the cutaneous nodules grew in size Many of the lesions showed flattening at the periphery, and a few lesions disappeared Since then all lesions have undergone involution except those on the face and neck The skin at the sites of former lesions has become brownish red There has at no time been any jaundice or pigmentary changes affecting the normal skin

A biopsy performed during infancy revealed a dense infiltrate in the cutis, consisting of epithelioid cells, the cytoplasm of which had a vacuolated appearance and simulated fat cells

DISCUSSION

DR SEYMOUR H SILVERS I followed 2 cases of xanthomatosis juvenilis for many years The patients came under my care during the first month of their lives I watched new lesions appear, and, as the children became older, the lesions gradually flattened out and finally disappeared I believe that, regardless of therapy, the lesions of xanthoma juvenilis will disappear when the child reaches the age of 6 to 7 years It is likely that xanthomatosis juvenilis should be classified with the nevi rather than with the diseases due to metabolic disturbances

DR ABRAHAM WALZER These patients should have a complete determination of the lipids of the blood Increased cholesterol does not necessarily imply that every case of xanthomatosis is due to cholesterol disturbance If any other fats are disturbed, the cholesterol may be increased in the blood To what is the yellowness of the cholesterol lesions due? Cholesterol and its esters are white, but the lesions are not The yellowness is probably due to a lipofuscin substance found in the fat

Tuberculosis Cutis with Papulonecrotic Sarcoid-Like and Colliquative Lesions Presented by DR S B FRISCHBERG

Alopecia Congenita Presented by DR C T CHIARAMONTE

D B, a white girl aged 9 years, has scant growth of hair on the scalp and eyebrows The deficiency is more evident in the frontal region There is pronounced follicular keratosis on the nape of the neck The child weighed 6 pounds, 2 ounces (2,778 Gm) at birth, was a breech presentation at delivery and gained weight more slowly than the average infant Since birth the hair on the scalp had always been sparse

The laboratory examination revealed absence of arsenic in the urine, a basal metabolism of + 13 per cent and a normal reaction for specific dynamic action of proteins A roentgengram of the sella turcica was normal

DISCUSSION

DR SEYMOUR H SILVERS Often, in addition to absence of or sparse hair, other ectodermal defects are seen It is not unusual to observe alopecia with dental and ophthalmic defects This child is mentally alert and bright.

DR JOEL SCHWEIG I am in favor of the diagnosis of the presenter, but I would advise cultures be made from the scalp and hair as the picture may turn out to be one of favus

Epidermolysis Bullosa Congenita Presented by DR C T CHIARAMONTE

G O, a white boy aged 4 years, has numerous bullae on the dorsum of the feet, some of which are hemorrhagic The toe nails and finger nails show atrophic and dystrophic changes Healed, erythematous lesions may be seen on the elbows and knees

There is no consanguinity of the parents It is interesting to note that this child has a nonidentical twin brother who is normal This child was first observed a few days after birth At that time, there were numerous cloudy bullous lesions scattered on the body, which I diagnosed as pemphigus neonatorum Culture from the bullae revealed the presence of Staphylococcus albus The lesions disappeared after treatment with sulfonamide drugs locally and internally Since then, however, blisters have been noticed by the parents to be reappearing on the extensor surfaces of the elbows and knees, on the dorsa of the feet and in the mouth

A Case for Diagnosis (Hodgkin's Disease?) Presented by DR C T CHIARAMONTE

L A, a white man aged 43 years, has a generalized, itchy eruption consisting of isolated, large, serrated papules These papules are brownish red, and some of them are excoriated There are also irregular groups of large vesicles, the tops of many present a small yellowish crust located on the extensor surfaces of both legs, arms and forearms and on the dorsa of the hands On the thighs the lesions have spread peripherally and form patches of crusted vesicles Groups of vesicles are present on the face, chest and abdomen Several of the original lesions have left a brownish pigmentation

The patient has had papular lesions and itching for the past seven months He first presented himself for treatment in January 1947, after having been treated elsewhere for scabies The past history reveals that the patient has had pulmonary tuberculosis, which was recognized in 1928 and was pronounced arrested in 1935, after a phrenicectomy In 1943 he received treatment for spastic colitis

A recent roentgenogram of the chest and examination of the gastric contents for tubercle bacilli did not reveal any abnormalities A biopsy of one of the papules performed in March revealed moderate acanthosis and parakeratosis with some hyperkeratosis The epidermis was infiltrated with eosinophils The corium contained many eosinophils, round cells and proliferating fibroblasts This inflammatory infiltrate was grouped around the small blood vessels The results of the urinalysis and hemogram were within normal limits The cholesterol content of the blood was 197 8 mg per hundred cubic centimeters and the cholesterol esters were 67 9 mg Roentgenograms of the long bones showed no abnormalities

DISCUSSION

DR C T CHIARAMONTE The biopsy was performed on one of the nodular purplish brown, persistent lesions I have known of cases of early Hodgkin's disease which was mistaken for scabies The patchy eruption on the arms, forearms and legs has appeared only in the past two months I shall observe him closely In the past few months, there has been a rise in the white blood cell count

DR NATHAN PENSKY The suggestion of Dr Chiaramonte must be seriously considered Several articles in the current literature have appeared on eosinophilic granuloma However, I have seen a number of patients who have been overtreated for scabies in which an eczematized eruption developed which clinically resembled

the rash in the case presented tonight The histologic observations in the present case would lead one to suspect the possibility of a lymphoblastoma

DR C T CHIARAMONTE Another thing of interest is the tuberculous background I feel that Hodgkin's disease and tuberculosis are in some way related

DR JOEL SCHWEIG I have the feeling that the diagnosis of Duhring's disease is the right one, as I have seen several instances of that condition which resemble clinically the case presented tonight My suggestion is that the patients be tested with potassium iodide, internally and externally, and that he be treated with sulfapyridine

Mycosis Fungoides, Developing On Parapsoriasis(?) Presented by DR C T CHIARAMONTE

Abraham Walzer, M D, *President*

Seymour H Silvers, M D, *Secretary*

May 19, 1947

Generalized Scleroderma Presented by DR L M FRUCHTBAUM

A M, a woman aged 70, was admitted to the Unity Hospital on Jan 6, 1947, because of acute cardiac decompensation Examination revealed edema of the lungs and of the legs The patient gave a history of progressive dysphasia for the previous three years, during which time she had noticed thickening and hardening of the skin of the forehead and face with inability to open the mouth wide The patient also noticed that she was unable to smile or frown and experienced difficulty in swallowing foods, particularly hard foods The hardening of the skin extended to the neck, shoulders, chest, back and thighs Examination revealed a waxy smooth skin adherent to the underlying soft tissues on the face, neck, trunk, shoulders and thighs The fingers and toes were not affected

The hemogram was within normal limits except for a leukocyte count of 12,500 per cubic centimeter Blood chemistry studies gave normal values for sugar and cholesterol, but the urea nitrogen was elevated to 28 5 mg per hundred cubic centimeters, and creatinine to 2 mg per hundred cubic centimeters The basal metabolic rate was —36 per cent The urine was normal Histologic examination of a specimen of skin showed scleroderma

DISCUSSION

DR JOEL SCHWEIG In view of the fact that there is so much edema present on the neck, as well as the lower extremities, I feel that the process is a deep-seated one and may be scleredema of the infectious type as described by Buschke Should it be of infectious origin, treatment with penicillin or sulfonamide drugs would be indicated and the prognosis would be more favorable A biopsy should aid in the final diagnosis

DR JACOB SKEER I also believe that there is too much edema present and that the extension of the lesion was rather rapid By this time there should be contracture of the tissues and other signs, like pigmentation The edema is of the nonpitting type and suggests Buschke's disease I think that a biopsy would give more information

DR SAMUEL I GREENBERG I think that this is scleroderma Scleredema is described in young adults, it follows infectious disease and is transient These aspects are not present in this case

DR DAVID M DAVIDSON I think that this is scleroderma The patient also has cardiac disease, and the pitting of the legs has nothing to do with her scleroderma I do not believe that this is scleredema of Buschke because the duration of the condition is three years and there is no history of a preceding infection

Urticaria Pigmentosa Presented by DR L M FRUCHTBAUM

DISCUSSION

DR C B LOCASTO It has been found that in animals given a diet free of vitamin A large numbers of mast cells develop in the tissues of the body In view of this, it is suggested that the patient receive large doses of vitamin A

Case for Diagnosis (Granuloma Annulare?). Presented by DR L M FRUCHTBAUM

Case for Diagnosis (Necrobiosis Lipoidica Diabeticorum? Granuloma Annulare?) Presented by DR I N HOLTZMAN

The patient, a white housewife aged 51, was first seen in the outpatient department of the Jewish Hospital of Brooklyn on May 12, 1947, with the following history

About five weeks prior to admission, she first noticed a nonitching eruption on both forearms and eyelids, which followed a mild abrasion of the left forearm The eruption has remained unchanged since its onset Her past history revealed the existence of diabetes mellitus of at least ten years' duration and a mild hemostatic eczema of the right ankle of about seven years' duration

Examination on admission revealed a papular eruption on the volar aspect of both forearms and eyelids The lesions varied in size from that of a pinhead to that of a pea and were faintly erythematous, and the larger papules were slightly yellow There was no characteristic grouping or configuration of any of the lesions

A biopsy of a lesion of the left forearm showed degeneration, necrobiosis and homogenization of the collagen with nuclear debris Surrounding and infiltrating into this zone were large collections of epithelioid foam cells Small round cells were occasionally seen Blood chemistry studies revealed a concentration of sugar of 181 mg and cholesterol of 261 mg per hundred cubic centimeters

DISCUSSION

DR JOEL SCHWEIG In my opinion the clinical features of the case fit in well with the diagnosis of lichen ruber moniliformis, which was well reviewed by Wise and Rein in 1936 The shape of the lesions, the color and the distribution are typical Although there is only one area on the right wrist presenting the moniliform features, it should be considered lichen ruber moniliformis, as those features may appear later in abundance The histologic observations are also like the microscopic features of lichen ruber moniliformis

DR DAVID M DAVIDSON When the patient was first seen at the clinic, a few diagnoses were mentioned, among them lichen moniliformis and lichenoid sarcoid When I examined the slide and saw that the main histologic changes

"The roof of the mouth is beefsteak red, and beefy and has a white exudate on it There are deep furrows The same picture is present on the sides of the cheeks and on the uvula The pharynx is red and 'angry looking' There is one small lesion on the gum over the left upper incisor"

An oral surgeon called in consultation stated The patient appears to have an inflammatory hyperplasia of the oral mucosa, very marked on the palate, with fissures I saw the patient at the suggestion of Dr John G Downing, who had seen the previous patient (case 2) at a meeting of the New England Dermatological Society and suggested that this patient probably had pyostomatitis vegetans The following is my consultation note

"Examination of the oral cavity shows a soft verrucous eruption of the hard and soft palate mucosa extending downward to include the uvula The mucosa of both cheeks shows folding in the molar regions but no active process at the present time Minute pinpoint whitish abscesses can be demonstrated in the lesions of the soft palate and uvula There are a few miliary abscesses in the upper part of the vestibule of the mouth in the cuspid regions The tongue shows an area of denudation of the coating, probably due to contact irritation from lesion of the palate The picture is strongly suggestive of a condition known as pyostomatitis vegetans"

Following is the report on the biopsy specimen taken from the palatal region of an old verrucous lesion

"The epithelial surface shows moderate hyperkeratosis and marked acanthosis with broadening of the rete pegs The underlying tunica propria shows a marked dense cellular infiltration with disorganization of the collagen fibers There is moderately increased capillary vascularization The cellular infiltration is very pronounced in the subepithelial zone and the papillas and extends into the epithelial surface forming dense collections of cells made up principally of lymphoid and plasma cells There is spongiosis of the acanthotic epithelium with many infiltrating lymphocytes extending to the surface epithelial layer The cellular infiltrate in the tunica propria is pleomorphic, with plasma cells predominating and relatively few polymorphonuclear leukocytes An occasional multinucleated cell is seen, and only a rare eosinophil is demonstrated The picture is that of a granulomatous inflammatory process of a chronic type The relative absence of eosinophils in this case as compared to the marked eosinophilia seen in early lesions can be explained by the age of the lesions The clinical picture together with the histologic findings indicates a chronic granulomatous process involving the oral cavity Two other cases of pyostomatitis previously seen by me differ only in that in more acute lesions the eosinophils predominate in the cellular exudate The diagnosis is pyostomatitis vegetans"

A report from the family physician received in November 1948 stated that there had been an improvement in the oral condition a year ago but that he had not seen the patient since that time

CLINICAL DESCRIPTION AND COURSE OF ORAL LESIONS

There was a remarkable similarity in the clinical courses in all 3 cases In cases 1 and 3 the disease was confined to the mouth throughout its entire course, and an opportunity to observe the primary lesions was presented in case 1 owing to a recent relapse after the mouth had been normal for three and one-half months

data, we think, force one to believe that at times granular cell myoblastoma may be malignant Ewing[18] expressed the opinion that most myoblastomas are benign

ORIGIN

Originally the theory was evolved that these tumors were degenerative lesions following injury or inflammation or that they arose from embryonal muscle cells Gray and Gruenfeld[19] stated the belief that the evidence for the theory is insufficient except for the tongue tumors The frequent appearance of the growths on the tongue has suggested the possibility of trauma This possibility was also suggested in Khanolkar's case 1, which followed a fall Crane and Tremblay in 1945 stated that "Definite statement as to the histiogenesis of these tumors is probably unwise at this time" Perhaps this opinion represents good judgment for the present

TREATMENT

As to their treatment, practically all authors agree that these tumors are not amenable to radiotherapy If they are recognized, it would seem to be good judgment for one to excise them, widely, if possible Otherwise, it would be well, if possible, for one to excise the growth and cauterize the base, if the lesion is small

The information concerning these tumors certainly suggests to dermatologists and surgeons the more frequent adoption of biopsy, otherwise many of them will not be recognized

CASE 1—N M, aged 71, a retired Naval officer, was admitted with the complaint of a sore on the tongue, of three weeks' duration

The patient had been a heavy pipe smoker for many years and had but recently noticed this spot on the tongue He did not remember having bitten himself

Physical examination revealed on the left side of the tongue, about halfway back and slightly toward the ventral aspect, a small, somewhat indurated, pearly white lesion, about 6 mm in diameter The area was slightly tender

With the use of local anesthesia the entire lesion was widely excised for biopsy and the base thoroughly destroyed with electrocautery The patient has been followed for two years and shows no evidence of recurrence of the lesion

The histologic report stated that the paraffin section stained with hematoxylin and eosin included buccal mucosa, a zone of atypical cells and underlying skeletal muscle The mucosa was hyperplastic, and irregular pegs extended deeply There was keratinization of groups of the deeper cells The cells were mature Mitoses in the epithelium were rare There was slight parakeratosis Pseudoepitheliomatous proliferation was striking

18 Ewing, J Neoplastic Diseases A Treatise on Tumors, ed 4, Philadelphia, W B Saunders Company, 1940

19 Gray, S H, and Gruenfeld, G E Myoblastoma, Am J Cancer **30** 699-708 (Aug) 1937

The primary lesions of *pyostomatitis vegetans* are noted as flat minute miliary abscesses on a slightly raised dark red inflammatory base The abscesses are *uniform in size*, suggesting early miliary tubercles, and tend to be more or less conglomerate, about 2 to 3 mm apart The process spreads within a very few weeks to involve the whole mouth, including the mucosa of the cheeks, the vestibule, the gingivas, the lingual aspects of the lips, the hard and soft palates and, to a limited degree, the margins of the tongue

As the condition develops chronically, the buccal mucosa begins to proliferate, is thrown into folds and assumes a verrucous appearance The miliary abscesses persist as fixed lesions and are found on the summits of the rugae and in the deep invaginations The mucosa is swollen, red and soft to palpation Under the dental plate in case 2 the miliary abscesses tended to rupture, leaving erosions with an accumulation of exudate becoming sticky from admixture with saliva This exudate could be peeled off, especially in the morning after inspissation from mouth breathing Smears from the miliary abscesses in the early stages show up to 30 per cent eosinophils and the remainder polymorphonuclear leukocytes

Only mild subjective symptoms occurred in each case, and the swollen verrucous lesions were not tender to the touch The verrucous mucosa acted as an insulating surface, and the ingestion of hot or spicy foods was not associated with any unusual discomfort In each case the course was relatively benign and of unusual chronicity with only slight periods of remission

The lesions of the oral mucous membrane were very distinctive and not simulated by those of any other oral disease

Although not a direct etiologic factor, the chronic diarrhea in 2 cases played an important role in lowering the resistance of both patients Both patients could be considered as below normal in their general health, and both had had recent acute infections, in case 2 the oral eruption appeared just after the attack of diarrhea had cleared up

The improvement in the oral disease in both cases was related to the use of liver and iron, together with prolonged vacations, rather than to any local treatment to the mouth

The cutaneous lesions in case 2 suggested an inoculation from the primary lesions in the mouth, but this was not proved The rapid spread of the vegetating cutaneous lesion of the groin was very striking and gave the clinical appearance of blastomycosis cutis The histologic picture was essentially the same as in the specimens removed from the mouth When the patient was hospitalized after three months of local treatment, the cutaneous condition responded to local antiseptic

Atypical cells extended from the inferior border of the epithelium, with which they were in immediate contact, to the underlying skeletal muscle They formed a broad sheet within which were occasional slender septums of connective tissue cells and capillaries Deeply, they mingle with the muscle fibers There were groups consisting in part of striated muscle fibers and in part of atypical cells The diameter of the atypical cells was larger than that of the muscle fibers, but these cells had the same general shape and had sharply outlined boundaries The cytoplasm was pale and finely granular and occasionally contained acidophilic clumps, in some instances they formed fine, parallel, linear, closely arranged, fibrillar lines Cross striation was not identified The nuclei were small but

Fig 1 (case 1)—Myoblastoma of the tongue, with pseudoepitheliomatous hyperplasia of mucosa, × 86

tended to be larger and more rounded than those of normal striated muscle They showed faint, weblike chromatin and, occasionally, a pale pink dot resembling a nucleolus Mitoses were not seen The atypical cells appeared to extend beyond the deep margin of excision

A frozen section showed no sudanophilic droplets in the cells

CASE 2—V B, a Negro woman aged 41, was first seen in April 1946, complaining of a small lump on the left side of her tongue The mass had been first noticed one year previously, was asymptomatic and had been slowly enlarging

The history, except for that of syphilis, which had been well treated, was not relevant

treatment together with radiation therapy There has been no recurrence of the cutaneous lesions in case 2 after several months, although a residual palatal process still persists

It was the cutaneous eruption in case 2 which made it possible finally to clarify the diagnosis of the oral disease in all the cases

BACTERIOLOGY

Smears and cultures from the oral cavity were taken in all cases and also from the cutaneous lesion in case 2 The following report was submitted by Dr Ralph Wheeler, Department of Bacteriology, Tufts College Medical and Dental Schools

CASE 1—Fresh unstained preparations showed numerous pus cells, desquamated epithelial cells, a few red cells and no amebas The dark field was negative for spirochetes Smears showed gram-negative diplococci and short bacilli as the predominating organisms A few gram-positive diplococci were seen, but acid-fast organisms were not demonstrated Wright stain showed 11 per cent eosinophils, but no Leishman-Donovan bodies Vincent's organisms were not found. Cultures on blood agar plates and anaerobic cultures showed a variety of organisms consistent with the normal oral flora, the predominating micro-organisms being gram-negative diplococci, gram-positive micrococci, nonhemolytic enterococci, streptococci of the viridans group and a single colony of aerobic actinomycetes, probably a normal inhabitant

CASE 2—Essentially the same general bacterial flora was found as in case 1 A long gram-negative filamentous organism was found but not identified Saliva filtrate inoculated into the allantoic membrane of chick embryo produced no growth Cultures from the miliary abscesses from the lesion of the skin of the groin showed Staph aureus with a few colonies of hemolytic streptococci

CASE 3—The cultures from the lesions in the oral cavity showed the predominant organism to be a streptococcus of the viridans group There were no beta hemolytic streptococci found on culture

It can be concluded that these findings, together with the clinical course of the disease, indicate that the oral and cutaneous manifestations are not related to the micro-organisms demonstrated

PATHOLOGY OF ORAL AND CUTANEOUS LESIONS

SIX biopsies in all were made from the oral lesions in all cases and one from the verrucous lesion of the skin in case 2

The general histologic pictures observed in these specimens were essentially the same The cutaneous lesions showed more pronounced hyperkeratosis with more extreme acanthosis and developed deeper invaginations of the surface epithelial layer. There was a more pronounced cellular infiltration with more numerous eosinophils in the upper part of the cutis and relatively larger miliary abscesses The oral lesions showed a marked acanthosis with broadening and elongation of the rete pegs with the epithelial surface thrown into folds, in places showing fairly deep invaginations Infiltrating eosinophil and poly-

On the left lateral border of the tongue, midway between the tip and the base, was a well defined, very firm, nontender tumor This measured 0 8 by 0 7 by 0 5 cm , was almost white and had a rough, somewhat verrucous surface Other oral mucosae were normal, but the teeth were extensively carious

Fig 2 (case 2) —Myoblastoma of the tongue, superficial part of tumor, with pseudoepitheliomatous hyperplasia, × 86

The entire lesion was widely excised and the base thoroughly cauterized Eighteen months later the patient was entirely cured

Histologic examination revealed this section to be almost identical with that for case 1 The atypical cells had the same distribution and appearance It was noted that some cells showed a mixture of appearances, in part resembling normal sarcoplasm At the periphery or at one side the cytoplasm might be

morphonuclear leukocytes were noted in the deeper epidermal epithelium A very striking and distinctive picture was the presence of epidermal miliary abscesses with the predominating cell the polymorphonuclear coarsely granular eosinophil leukocyte Focal areas showing epithelial thinning with necrosis at the site of rupture of miliary abscesses were present The tunica propria showed a very marked cellular infiltrate, chiefly eosinophilic, especially in the region of the papillae Deeper in the specimens the cellular infiltration was slight to moderate In addition to the cellular infiltration of the tunica propria, there was considerable edema with increased capillary vascularity Proliferation of the endothelium in the young blood vessels was noted

The over-all picture was that of a granulomatous inflammatory process with unruptured miliary epidermal abscesses and focal areas of surface necrosis The tissue and blood eosinophilia was striking in 2 cases, although not diagnostic, as eosinophilic infiltration of tissue lesions and the presence of eosinophils in the peripheral blood stream are commonly observed in pemphigus vegetans, dermatitis herpetiformis and other dermatoses

DIFFERENTIAL DIAGNOSIS

When first seen and for several months afterward the disease involving the oral cavity remained undiagnosed, and it was only after the characteristic verrucous lesion of the skin in case 2 developed that a definite diagnosis was made

In pemphigus vegetans, oral lesions are characterized by a primary flaccid bullous lesion which contains a serous fluid tinged with blood These bullae rupture early, leaving superficial painful eroded areas New lesions continue to form, and the oral condition presents a characteristic appearance Desquamated epithelium and a fibrinous exudate frequently coat the superficial ulcerations In very chronic oral involvement, focal areas of proliferating granulation tissue may develop but the process is very painful

In the very rare oral disease oral pemphigus, in which the lesions are confined to the mouth, the primary lesions are also bullous and the process may continue for years Extension to the pharynx may occur in these cases, and pain is a prominent symptom

Dermatitis herpetiformis has been described as a disease that may cause cutaneous lesions similar to those described in pemphigus vegetans Oral involvement in dermatitis herpetiformis has been described, with lesions essentially the same as in pemphigus vegetans However, many dermatologists state definitely that the mouth is not involved in this disease, and I have never seen a single case of dermatitis herpetiformis with oral lesions

brightly eosinophilic and compact, as in normal striated muscle cells, while centrally or at an opposite side it was loose, pale and granular Cells of intermediate intensity of staining were also present They had loose fibrils and faint cross striations and resembled skeletal muscle except that they were larger and paler No mitoses were present The atypical cells extended to the depth of the section The epidermis was similar in every respect to the section from case 1

Fig 3 (case 2) —Myoblastoma, deep portion of tumor, in which may be seen mixture of the granular cells with the striated muscle of the tongue, × 134

There was more parakeratosis, however, and an extreme pseudoepitheliomatous hyperplasia

CASE 3[20]—L S, a man aged 40, had had a gradually developing tumor in the anteropalmar aspect of the distal phalanx of the right thumb for four years

20 Included through the courtesy of Dr J M Hamilton and of Dr D J Rehbock, clinical pathologist, St Vincent Charity Hospital

Lupus erythematosus not infrequently shows buccal lesions which tend to ulcerate early and usually are associated with subjective symptoms of pain and soreness, although some patients are relatively free from pain The lesions are sharply defined and their appearance varies with the age of the lesion The common locations are on the lips and in the vestibule of the mouth, especially in the molar regions The palate and gingivas, together with other locations, may be involved The lesions in the beginning are bright red plaques with slightly infiltrated borders, with thinning of the centers as the lesions progress Many of these lesions as they heal resemble those of leukoplakia

Eosinophilic granuloma,[18] regarded by many as an entity, has in recent years been described in the dermatologic literature The complexity of the clinical picture and a more specific histologic picture help to differentiate this condition from the oral and cutaneous lesions of pyostomatitis vegetans To date there has been no mention of oral lesions in all the cases of eosinophilic granuloma reported in the literature

TREATMENT

As indicated in the description of these cases, local therapy had no effect in clearing up the lesions Local and parenteral administration of penicillin and oral administration of sulfonamide drugs had no beneficial effect on the mucosal lesions Use of iron and liver together with prolonged vacations was effective in aiding the return to normal of the buccal mucosa in case 1, and in case 2 a similar result was accomplished except for a residual process on the palate after twenty-two months In case 3, according to the most recent report, in 1947, there was improvement in the oral condition with a residual process still persisting in the palate region

SUMMARY

Three cases of a rare vegetating oral mucosal disease are described in 1 of which typical pyodermatitis vegetans developed, in the others the condition remained as an oral entity

Pyostomatitis vegetans presents a characteristic and distinctive oral disease with primary miliary abscesses on an inflammatory base with the development of verrucous changes

The clinical course in 2 cases was confined to the oral cavity, these are the only cases reported in the literature in which the disease remained an oral entity

18 Weidman, F M The "Eosinophilic Granulomas" of the Skin, Arch Dermat & Syph **55** 155 (Feb) 1947 Lewis, G W, and Cormia, F E Eosinophilic Granuloma, ibid **55** 170 (Feb) 1947 Lever W F Eosinophilic Granuloma of the Skin, ibid **55** 194 (Feb) 1947

The tumor was freely movable and completely painless There was a history of catching the thumb in a door jamb and pinching it severely some months before In fact, the injury had been so severe that the patient had only a spoon nail on that digit. His occupation was not relevant

The tumor was only recently excised through an incision of the skin without removal of skin There were no other lesions

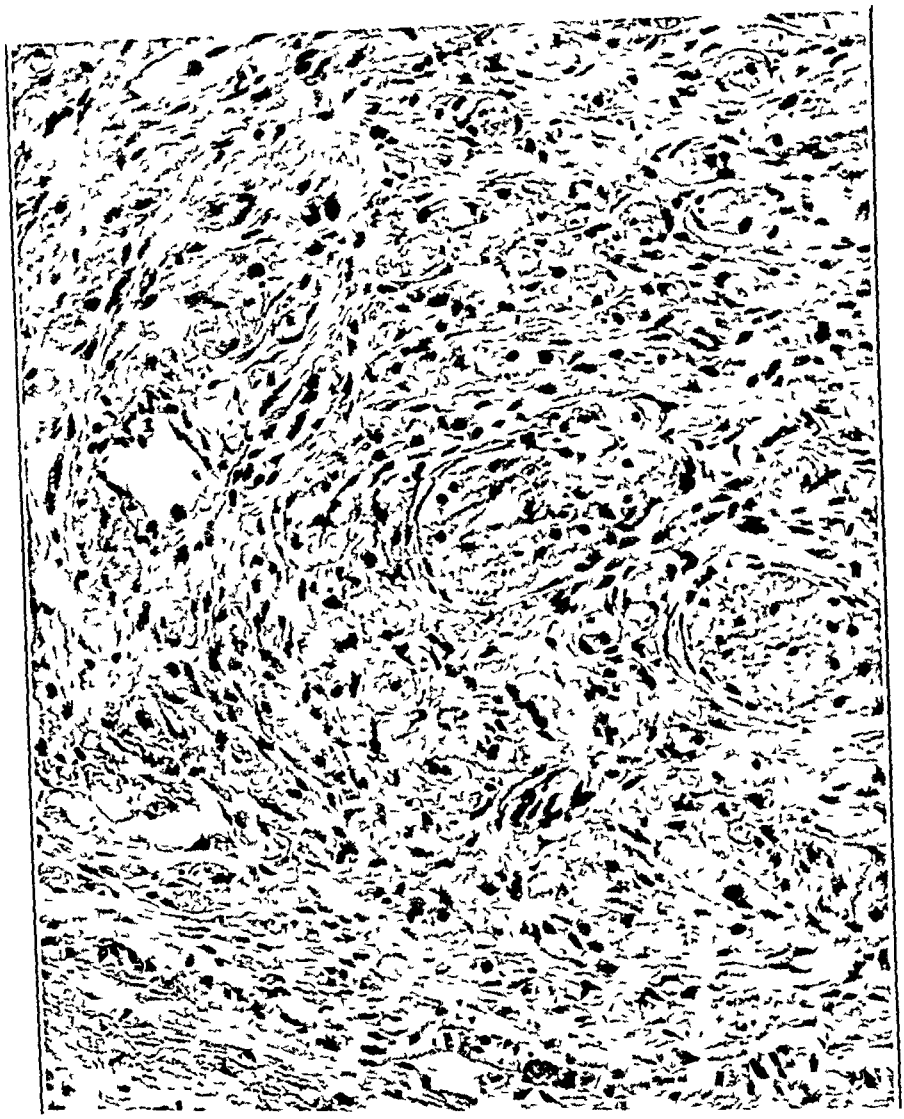

Fig 4 (case 3) —Granular cell tumor of finger, with coarse granularity of cells, about × 200

The specimen consisted of an ovoid, firm, pearly gray tissue mass, measuring 1 0 by 0 6 cm The surface was lobulated but otherwise smooth Section revealed a firm, fibrous, pearly gray tissue

The paraffin section stained with hematoxylin and eosin consisted largely of rounded groups of atypical cells enclosed by a circle of fusiform cells and hyaline fibers These groups were in turn collected and held together by interlacing bands of hyaline fibers, and the entire mass was bounded by collagenous tissue on two sides Outside of this capsule were a little areolar tissue and a few sweat glands The other two sides were cut surfaces

In case 2 a complicating vegetating dermatitis developed, the pathologic picture presenting the same changes as were found in the oral lesions in the 3 cases

The oral lesions were resistant to local oral therapy in all cases, but the cutaneous lesion responded to antiseptic and radiation therapy

Bacteriologic study of the oral lesions in all 3 cases revealed no specific micro-organisms or virus

A similarity to pemphigus vegetans is indicated, but the clinical course with characteristic oral lesions indicates a definite disease entity involving the oral cavity

The atypical cells were round and polyhedral or long and cylindric They were granular and moderately eosinophilic The granules were fine, although a few coarse hyaline clumps were seen Indistinct cross markings were seen Some of these appeared as very fine basophilic lines, and others had an appearance produced by parallel arrangement of granules Some nuclei were basophilic, compact and small Others were larger and showed a reticular and punctate chromatin pattern Single or multiple nuclei might be seen in a single cell Where cells were longitudinally cut, spaced nuclei might be seen in a row Mitoses were not present

COMMENT

In the two lingual lesions there were transitions from striated muscular cells to granular atypical cells (fig 3) It is reasonable to conclude that for these the term myoblastoma is justified

In case 3, however, there were differences The cells were larger and more coarsely granular, and there was grouping in round nests, in contrast to the uniform sheets found in the lingual lesions Muscular relations were not seen Further, the tumor arose in a site away from normally situated skeletal muscle The histologic diagnoses entertained were myoblastoma, traumatic pseudoneuroma and neurofibroma The first-mentioned one seemed the most likely

At this juncture the presentation of Fust and Custer [21] concerning granular cell neurofibroma was heard, and the slide was sent to them for an opinion They expressed the opinion that it was an example of granular cell neurofibroma

Without further study concerning the nature of these tumors, and pending the publication of Fust and Custer's work, we choose to call the lesion a granular cell tumor and to be noncommittal concerning its origin

SUMMARY

A report is made of 2 cases of granular cell myoblastoma of the tongue and of a subcutaneous granular cell tumor of the thumb They are discussed from a clinical and microscopic standpoint

Such tumors are probably much commoner than is suspected

The tumors are found most frequently on the tongue and in the mouth and appendages, they are seen next most frequently on the skin and subcutis

While in most cases these tumors are not malignant, nevertheless sufficient reports are accumulating to indicate that in certain locations and under certain conditions invasion, metastases and death may result from less than total surgical removal The tumors are highly radioresistant

NONLIPID GRANULAR CELL TUMORS

HAROLD N COLE, M D
AND
HERBERT LUND, M D
In Collaboration with H N Cole Jr, M D, J R Driver, M D, Richard C Light, M D, and Don R Printz, M D
CLEVELAND

NONLIPID granular cell tumors are usually considered to be myoblastomas, and in the following review this term will be used freely However, identity of all these tumors is still open to question We present 3 cases exemplifying this problem

In 1926 Abrikossoff [1] reported a tumor of myoblasts occurring chiefly in relation to striated muscle He thought it might be due to degenerative lesions following injury or inflammation In 1931 [2] he further elaborated his ideas on myoblastic myomas, as he called them, feeling that perhaps they were made up of embryonal elements primitive myoblasts He divided them into four different types, of which the first three are all granular cell and benign (1) round, egg-shaped or elongated myoblasts, 20 to 25 microns in length, showing granules but no longitudinal or cross striations, (2) growths in which some of the cells may show longitudinal or cross striations, and (3) a hypertrophic form with cells 40 to 160 microns in length and at times multinucleated. He also described a further type (4), in which the myoblasts are not granular but atypical, which resembles more a polymorphous sarcoma

Crane and Tremblay,[3] in reporting 5 cases in 1945, pointed out that, although Abrikossoff had reported 5 cases in 1926, Weber in 1854, Hertaux in 1881, Pendel in 1897 and Moschcowitz in 1922 had described what were apparently identical lesions Crane and Tremblay reviewed

Read at the Sixty-Eighth Annual Meeting of the American Dermatological Association, Inc, San Diego, Calif, April 28, 1948

From the Department of Dermatology and Syphilology and from the Institute of Pathology of the Western Reserve University School of Medicine and of the University Hospitals

2 Abrikossoff, A I Weitere Untersuchungen uber Myoblastenmyome, Virchows Arch f path Anat **280** 723-740, 1931

3 Crane, A R, and Tremblay, R G Myoblastoma (Granular Cell Myoblastoma or Myoblastic Myoma), Am J Path **21**·357-375 (March) 1945

There are a few cases in which these growths have been multiple in type on the skin and subcutis as well as in internal organs

In tumors of the skin and mucous membrane, the pseudoepitheliomatous hyperplasia is frequent enough to be noteworthy

The tumors of the tongue strongly suggest muscular origin Other tumors without demonstrable transition from or location in muscular tissue are more obscure The work of Fust and Custer is anticipated

ABSTRACT OF DISCUSSION

DR HAMILTON MONTGOMERY, Rochester, Minn I have been interested in myoblastoma ever since Dr Machacek called my attention to this condition several years ago when the American Academy of Dermatology met in New York A fellow in pathology at the Mayo Clinic, Dr G H Murphy, just finished studying 10 cases which he classified under the headings of the uniform type of myoblastoma, which is benign, and the pleomorphic type, which is essentially a rhabdomyosarcoma The granular cells appear in both types I had formerly accepted the concept that granular cell myoblastoma arose from skeletal muscles Recently, however, I have seen 2 cases in which there apparently was origin from smooth muscles In 1 case there was a lesion on the vulva of a Negro woman aged 72, which showed smooth muscle origin Material from a recent case with involvement of the anal region, sent to me by Dr Wasserman of Cincinnati, showed granular myoblastoma cells apparently arising in relation to the walls of the capillaries in the papillary bodies This observation would suggest endothelial origin, because these capillaries are not supposed to have a muscular coat In some of Murphy's cases of the pleomorphic type, there was a history of trauma preceding the development of the tumor and subsequent metastasis and death Myoblastoma does not have a typical clinical appearance but does have a characteristic histologic one

DR ANTHONY CIPOLLARO, New York My attention was brought to this disease several years ago when a patient came to my office with a small lesion on the tongue I diagnosed it as a fibroma I was going to infiltrate it with procaine hydrochloride (novocain®) and destroy it with electrodesiccation, but, because the man was worried about cancer, I removed the tissue and submitted it for biopsy The type of lesion was not recognized by the first dermatopathologist It had unusual cells with which I was not familiar Dr Richter, a general pathologist, immediately diagnosed it as a granular cell myoblastoma This case was published by me a few months ago in the ARCHIVES [12]

I think that all nodular lesions of the tongue should be removed and submitted to the laboratory for histologic study

DR. LOUIS WINER, Hollywood, Calif Recently my associates and I had submitted to our laboratory a piece of tissue which showed myoblastoma The differential stains were very interesting Van Gieson stain colored the blastoma tissues yellow, like smooth muscles Mallory's stain showed the tissue to be bright red, just as it does muscle fibers Therefore, I would advise that differential staining be done In the case of neurofibromatosis, also, differential stains would be of benefit because the tissue in neurofibromatous structure is mostly fibrous and stains like connective tissue, red with Van Gieson and greenish blue with Mallory's stain

the literature, which up to the time of their publication consisted of 162 cases, 34 of the skin and subcutis and 61 of the tongue

In the past few years there has been much more interest directed to this group of tumors, with quite extensive reports, among others those by Klemperer,[4] Howe and Warren,[5] Ravich, Stout and Ravich,[6] Powell [7] and Khanolkar [8] Reports on the disease, as it has become better known, have mounted rapidly, thus Powell reported 4 cases in 1946, Simon,[9] 6 in 1947, Khanolkar, a further 10 in September 1947, and Allen,[10] 27 in 1948 The total, including Bloom and Ginzler's,[11] Cipollaro and Einhorn's [12] recent cases and our 3 cases, is around 214 cases It is our view that as the entity becomes better known and as the physician becomes more inclined to examine lesions histologically, granular cell myoblastoma will be found to be far from a rare entity Thus Allen found 27 myoblastomas in material from 8,000 specimens of cutaneous diseases collected in World War II by the Army Institute of Pathology

LOCALIZATION AND CHARACTERISTICS

These tumors seem to be found most frequently on the tongue and in the mouth and larynx, in about some 37 per cent of the cases The growths have been distributed all over the body and in some internal organs

Strangely enough, the occurrence of these tumors in the second most frequently involved area, the skin and subcutis, has not been sufficiently emphasized until in the very recent literature Powell in 1946 stated that 20 4 per cent of the cases so far reported had involved these structures In 3 of her 4 cases the cutaneous surfaces were affected—

DR HARRY ARNOLD JR, Honolulu, Hawaii I should like to mention in this connection an instance of a small lesion on the side of a young woman's neck, clinically an obvious granuloma pyogenicum, which was sectioned in our laboratory purely as a routine matter and turned out to be an infiltrating, anaplastic, granular cell carcinoma, the cells of which were full of fat It was an example of the sort of lesion Dr Cipollaro spoke of, which is all too frequently merely thrown away after its removal Excision of the operative site the following afternoon revealed a nest of residual neoplasm

DR HAROLD N COLE, Cleveland Thank you all for the discussion I mentioned a classification of these tumors containing four groups The fourth group is that of a nongranular polymorphic sarcoma, generally not accepted as a granular cell myoblastoma, and should be deleted

in 1 with multiple lesions Tuta and Schmidt[13] in 1942 reported 3 examples of cutaneous involvement and 1 of the trapezius muscle Ebert and Slepyan[14] the next year presented a patient before the Chicago Dermatological Society with a small nodule on the dorsum of the left hand In the discussion Becker[15] stated that he had recently seen in consultation with Dr Clarence Shaw a similar tumor on the upper part of the chest Then Bloom and Ginzler reported the case of a Negro woman with a hazelnut-sized, round, raised tumor of the lip which, after endothermy, was followed two years later by a hazelnut-sized nodule of the skin and subcutis of the right thigh, a similar lesion on the trunk and a smaller one on the right hip Very recently Cipollaro and Einhorn observed a marble-sized nodule of the right index finger as well as one on the tongue There have been a few instances reported of polyp-like masses in the ear canals, which growths may attract attention by bleeding

These tumors are very often symptomless, are many times sessile and vary in size from 0 5 to 2 0 or 3 0 cm , occasionally being even larger Their color on the mucous membrane is often described as grayish or opalescent In Ebert and Slepyan's case the quarter-sized mass was made up of several smaller nodules Rarely are the growths painful unless in a vital structure and ulcerating as well The patients vary from newborn babes with small lesions of the alveolar processes up to persons in the second, third or fourth decade of life, rarely older

MICROSCOPIC APPEARANCE

These tumors are generally well circumscribed, ovoid or lobulated and rather firm Occasionally the borders may show outlying islands of cells and may even penetrate surrounding tissues The growths are made up of rather large, elongated or polyhedral cells, appearing as single cells or in sheets They may have a banjo or tadpole shape or the shape of a tear drop, as has been mentioned by many writers And some tumors will show a striking pseudoacinar appearance of the cells They have a coarse, granular cytoplasm, acidophilic in character, and nuclei that are comparatively small and have an angular appearance In some cases the cells may be multinucleated The cytoplasm is often foamy, resembling somewhat that of a xanthoma cell However, it does not have the tinctorial reactions of the latter Occasionally the cells

USE OF REPELLENTS IN CLINICAL DERMATOLOGY

General Principles

LEON GOLDMAN, M D
CINCINNATI

AMONG the advances in preventive medicine in the last world war were the detailed studies in the chemical control of insects As yet, the practicing physician, as compared with the military physician does not appear to be fully aware of the possibilities for the control of insects, especially the disease-bearing types This chemical control, in general, falls into two phases insecticidal and repellent activity

The development of insecticides is well known from the advances in the preparations of pyrethrins and DDT (2,2-bis [p-chlorophenyl]-1,1,1-trichloroethane) and its newer analogues, such as DDD (1,1-dichloro-2,2-bis-[p-chlorophenyl]-ethane) and methoxychlor (1,1,1-trichloro-2,2-bis [p-methoxyphenyl]-ethane Perhaps less is known about the developments of new insecticidal materials, which include such substances as gammexane® (hexachlorocyclohexane), velsicol 1068® (also called chlordan), hexaethyltetraphosphate, piperine compounds, parathion (0,0-diethyl-0-p-nitrophenyl thiophosphate), very toxic, phenyl cellosolve® (ethylene glycol monophenyl ether) and eura® (10 per cent crotonyl-N-ethyl-ortho-toluidide) [1] Dermatologists should be interested also in the development of effective modern rodenticides, such as 1080, alpha-naphthyl-thiourea, and fanyline

Repellents have a distinct and important value because they serve, by means of a protective cloud of volatile products about the person, by taste mechanisms, by physical or mechanical means, etc, to keep insects away Repellents are necessary, for it may be possible for one to be bitten during the latent period of activity of an insecticide At present, it is not possible to combine in a single universally effective mixture both insecticidal and repellent properties Prior to World War I, few, if any, effective repellent materials were available Smokes and oil of citronella were old favorites During World War II thousands of compounds [2] were tested, and continued to be tested, for their repellent and toxic qualities against mosquitoes, lice, mites, ticks and "other

From the Department of Dermatology and Syphilology of the University of Cincinnati College of Medicine

in certain tumors will show suggestions of longitudinal or cross striations Keynes [16] and Klemperer pointed out the interesting feature of overgrowth of the overlying epithelium where the skin or mucous membrane is concerned—a pseudoepitheliomatous hyperplasia This condition was striking in the cases of Bloom and Ginzler, even to the production of pearls, which the pathologists interpreted as indicative of a low grade squamous cell carcinoma

MALIGNANT GRANULAR CELL TUMORS

Originally, Abrikossoff separated a fourth group of tumors resembling more a polymorphous sarcoma, which is quite generally not included in the classification of granular cell myoblastomas Howe and Warren reported that they had seen 10 cases, among which there were 5 with definite malignant properties, 3 of the growths metastasizing to the lung They also stated that they had found 10 cases in the literature and 4 of their own with either gross or microscopic evidence of local invasion There had been regional adenopathy in 7 cases, but in only 3 were metastases to lymph nodes proved by biopsy In none was there response to irradiation Ravich, Stout and Ravich expressed the opinion that all 5 of their cases should be put in Abrikossoff's fourth class They were skeptical of the malignant character of this tumor until the occurrence of their own case, in which a tumor of the bladder recurred after excision and in which the patient died eleven months later from metastases They stated the belief that their case is the first example of a type 3 tumor metastasizing and causing death However, in Morpurgo's [17] case the patient, with a tumor of the tongue, died with metastases in the cervical nodes In Powell's patient 3, who had a large growth in the floor of the mouth, displacing the tongue, there was invasion of the tissues and death from erosion of a vessel Moreover, in her case 4 there were tumors in the scalp, the upper eyelid, the lower lip, the right axilla, the right side of the torso, the left thigh, the vulva, the back, the toe and the buttock, as well as of the uterus and an ovary After removal of some of these, including the uterine and ovarian growths, further growths developed on the skin This development of further cutaneous lesions also occurred in Bloom and Ginzler's case after partial removal of the tumor of the lip Moreover, Khanolkar, in a recent article, reported a further 10 cases in which there could be no uncertainty regarding the neoplastic nature These

arthropods affecting the health of man" [8] The brilliant researches of the various governmental groups are especially known by the studies on DDT However, equally important work has been done, and continues to be done, especially by the Bureau of Entomology and Plant Quarantine of the Agricultural Research Administration, in the investigation of repellents Effective mixtures, well known to military physicians, were the dimethylphthalate solutions and the dimethylphthalate combined with hexanediol and indalone® (butyl ester of 3,4-dihydro-2,2-dimethyl-4-oxo-1,2-pyran-6-carboxylic acid) Toward the end of the war, Pijoan [1] and Jachowski,[1] working at the Naval Medical Research Institute, developed the NMRI-448 repellent This compound represents the four hundred and forty-eighth attempt to find an effective repellent mixture, which essentially was the combination of 70 per cent 2-phenylcyclohexanol and 30 per cent 2-cyclohexylcyclohexanol Jachowski [1] claimed that NMRI-448 is superior to the 612 and the 622 mixture in effectiveness against the mosquitoes of tropical America and of equal effectiveness against the mosquitoes of the United States and Alaska Recent work has indicated that N-propyl-N,N-diethylsuccinamate has also good repellent action when applied to the skin Recent work by Brennan [3] has also included the development, especially as a repellent for ticks (Dermacentor andersoni, Amblyomma americanum), of phenylcyclohexanol and butylacetanilide Our preliminary studies with N,n-butylacetanilide indicate that this material is also of low sensitivity index

With regard to the protection of the person, the two significant features of repellent activity are, first, the limitation of the protection to the area or areas to which the repellent has been applied and, second, the duration of activity of the repellent action In general, the repellent mixture in a suitable vehicle may be used locally on the skin, or clothing may be impregnated with it The duration of the activity varies with the type of repellent, and perhaps with the type of vehicle The recent development in the use of repellents has increased the time of repellent activity to approximately eight hours for the NMRI-448 group Clothing impregnation prolongs the period of repellent activity Against ticks, the repellent activity is said to last as long as twelve days

Repellents in dermatologic practice are useful specifically in preventing chigger infestation and bites, mosquito bites, fly bites and flea bites, they act as a tick repellent and possibly are of value in management of the familial infestations pediculosis and scabies

Protective clothing and various types of sulfur preparations have been used to prevent chigger (genus Trombicula) infestations In

3 Brennan, J M Preliminary Report on Some Organic Materials as Tick Repellents and Toxic Agents, Pub Health Rep **62** 1162, 1947

consisted of local granular necrosis with cellular debris surrounded by many epithelioid cells and a few connective tissue cells, I was inclined to consider the case as one of granuloma annulare, although the patient did not have any ring lesions I have seen a few patients with granuloma annulare with scattered papules, but they also had the typical annular lesions However, Hartzell (*J A M A* **63** 230 [July 18] 1914) and Stillians (*J Cutan Dis* **37** 580, 1919) each reported a case of granuloma annulare without ring lesions, and the latter mentioned many others who had observed similar cases

The patient has definite lichenoid papules, some resembling lichen planus, although the lesions are softer to the touch than those in lichen planus There is no moniliform arrangement and no waxy papules as were described in lichen moniliformis Another interesting point in this case is that the patient has diabetes but clinically the lesions do not suggest necrobiosis lipoidica diabeticorum, and histologically one often finds extensive vascular damage in necrobiosis as well as in lichen moniliformis, features not found in this case and usually not seen in granuloma annulare In consideration of all this, I am inclined to consider this as a case of granuloma annulare

Xanthoma Tuberosum Presented by Dr L M Fruchtbaum

Epithelioma of the Cheek in a Woman Aged Twenty Years Presented by Dr Seymour H Silvers

Acrokeratosis Verruciformis of Hopf Presented by Dr C B Locasto

M C, a Negro woman aged 52, stated that she has had thick skin on the palms and soles and wartlike growths on the back of her hands since birth There are no subjective symptoms The palmar and plantar surfaces are hyperkeratotic The dorsal aspects of the hands and feet and the distal parts of the forearms are studded with numerous, discrete, confluent and flat-topped verrucalike polygonal papules The nails are frayed distally, have vertical linear striations and are brittle

DISCUSSION

Dr Joel Schweig This is an unusual case and of a type rarely seen at our meetings I agree with the diagnosis Acrokeratosis verruciformis and epidermodysplasia verruciformis are different in that the latter appears in persons with consanguineous parents and is associated with malignant degeneration of the lesions The concept of this condition is that it is of nevoid character

Tinea Capitis in an Adult (Microsporon Lanosum) Presented by Dr E A Gauvain

T A, a widow aged 73, had been losing hair for four months She complained of slight itching of the scalp She had no recollection of direct contact with dogs or cats, but a dog had been a recent visitor to one of her neighbors

The hair of the scalp is thick and long, with many areas showing slight erythema and definite defluvium without any sharply defined areas of alopecia Under the Wood light, fluorescent hairs mingled with nonfluorescent hairs are seen throughout the scalp A culture of infected hair grew Microsporon lanosum

Systemic Blastomycosis Presented by Dr D Omens and (by invitation) Dr H Omens and Dr J Graffin

S W, a Negro woman aged 39, on Dec 24, 1946 precipitously delivered a full term baby while on the street Several days later she noticed a few nodules on the right forearm, which gradually grew to form abscesses In the next two months numerous fluctuant, hen's-egg-sized abscesses appeared on the face and extremities, and, in addition, warty lesions developed on the face and trunk For the past few weeks she has had fever, "night sweats," headache and malaise, but no symptoms referable to her gastrointestinal, respiratory or genitourinary tract Until the time she entered the Cook County Hospital, she had nursed her apparently healthy baby Her other four children and her husband have been in good health She has not been out of Chicago in the past two years and has no contact with flowers, gardening or animals

Examination reveals numerous fluctuant, tender, subcutaneous abscesses scattered on the face, extremities and back, varying from 1 to 5 cm in diameter In addition, there are verrucous nodules on the face and trunk Physical examination revealed no other abnormalities While in the hospital she has had a low grade fever daily, accompanied with headache and malaise

The Kahn reaction of the blood was negative The urine was normal The blood examination showed erythrocytes 4,600,000, hemoglobin 67 per cent and leukocytes 22,200 Sterile aspiration of a subcutaneous abscess resulted in recovery of blastomycetes on culture Direct sodium hydroxide preparation revealed numerous round doubly refractile bodies, some of which were budding The blastomycin intracutaneous test revealed a 12 mm erythematous papule at 24 hours, but at 48 hours the papule was only 5 mm in diameter The roentgenogram of the chest revealed a normal cardiothoracic ratio There was a small discrete

recent years, I have used benzyl benzoate preparations on the lower extremities as a protective measure King has indicated that for uniform impregnation against chiggers these five new compounds are all superior to benzyl benzoate, benzyl, 2-thenyl benzoate, p-cresyl benzoate, diphenyl carbonate and 2-thenyl salicylate The modern repellent for the prevention of chigger bites are rubbed in from the ankle to the knee, they are also put into the cuffs of trousers, clothing may be impregnated and the substance rubbed into shoes The technic of this application refers to protection of the person only while he is walking through chigger-infested areas, for sitting or lying in the grass, however, greater areas of the body must be protected Besides the usual severe discomfort from these bites, significant reactions may occur in the elderly, in persons with latent and actual stasis syndromes and in infants and young children with extensive bites Parkhurst [1] emphasized repeatedly the necessity of preventing bites from the chigger For the use of repellents against flying insects, such as flies and fleas, the repellent must be used on the exposed areas of the skin Such areas include chiefly the head, neck, neck line, wrists, arms and trouser line It should be remembered that the repellent must be reapplied if the supposed period of activity has been exceeded When repellents are mixed in "sun tan mixtures," one must consider the possible insect-attracting qualities of these mixtures

For those insects which serve as vectors for disease, such as ticks, mosquitoes, simulia and flies of the Phlebotomus group, these repellents have an importance far beyond the prevention of the mere initial cutaneous bite In a previous report,[4] the relation of the lichen urticatus syndrome in children to bites from insects was shown For those children, repellents are needed, especially against fleas, chiggers and bedbugs Tick repellents also may be applied to the skin or the clothing impregnated Although repellents should have value in familial infestations with Phthirus pubis, Pediculus capitis and Sarcoptes scabiei, few controlled studies on civilian groups are available In practice, actual antiparasiticidal treatment of the entire family, especially in the case of scabies (scabies domestica), is carried out, and the repellents, though less irritating, are not needed

The mixtures of repellents that were developed by the armed services during the war have undergone, in addition to severe critical laboratory use and field trials, controlled tests with regard to systemic

One of our patients was born and remained in San Diego county until his entry in the Navy, while the other was born in North Carolina, his only possible contact with the organism coming while he was stationed in San Diego Lee's [10] experience with certain bodies of troops indicates a high percentage of infections when men are exposed to very dusty conditions in an endemic area The recent drought in California poses an additional hazard in the spread of the infection It has also been shown that animals in endemic areas harbor the infection, and the possibility of a rodent reservoir has been advanced Since the infection is carried in dust, the possibility of dissemination in vehicles and luggage of those traveling in and out of the endemic areas cannot be entirely discounted Although the danger on the present evidence is very slight, it is not yet definitely known whether or not the many thousands who were infected during their training period in an endemic area may have serious complications later in life

SUMMARY AND COMMENT

Much has been added to the knowledge and understanding of coccidioidomycosis in the past decade The endemic areas have been redefined and are known to extend over the southwestern United States and northern Mexico The patients in our cases undoubtedly contracted their infections in San Diego county, which had not been considered an endemic area They were both from dark-skinned races, in whom the progressive disseminated, frequently fatal form is most likely to develop Lesions of the gastrointestinal tract, which are said not to occur but have been recorded in the literature on one other occasion, were found widely distributed in 1 of our cases Although the infection in most instances is entirely benign and complete clinical recovery can be anticipated in even those who have pulmonary involvement with cavitation, possible serious complications may develop in later life in some of the many persons who were infected during their training period in an endemic area during the last war The similarity to and distinction from tuberculosis of this disease will become increasingly important to physicians everywhere, since these men have now returned to their homes throughout the United States Specific treatment is still lacking, and neither drugs nor vaccines have appreciably altered the course of the progressive disseminated form

REACTIONS IN TATTOOS (CHRONIC DISCOID LUPUS ERYTHEMATOSUS)

JOHN F MADDEN, M D
ST PAUL

Reactions in tattoos generally fall into one of four groups The reactions in one group consist in the immediate response of the skin to the physical injury of tattooing This is rarely accompanied with or followed by secondary infection In

From the Department of Dermatology, Ancker Hospital, St Paul, Dr John F Madden, Director, and the Division of Dermatology and Syphilology, University of Minnesota Medical School, Dr H E Michelson, Director, Minneapolis

toxicity and cutaneous irritation and sensitivity As an example, to develop a technic of screen testing for rapid elimination of those compounds which would be harmful to man and animals, Draize, Nelson and Calvery [4] devised a detailed percutaneous toxicity test on animals The materials that are available now, as a result of such extensive cooperative work, are mixtures with a low sensitivity index

From experience, it appears that the discomfort suffered with the use of repellents is usually caused by its vehicles, alcohol or other solvents, rather than by the repellents themselves It is the solvent that is responsible for the burning around the eyes and mouth and on active sunburned areas For some time cream vehicles, with a content of liquid repellent varying from 10 to 60 per cent, have been suggested by the Orlando Florida Laboratory of the Bureau of Entomology and Plant Quarantine of the Agricultural Research Administration In general, a cream type of vehicle is preferable

Persons traveling to tropical or subtropical areas should receive, in addition to their protective inoculations, simple and practical instructions regarding the modern uses of insecticides and repellents The dermatologic aspects of modern insecticides will be reported in another article

CONCLUSION

Greater use should be made by the civilian dermatologist of the recent advances in the chemical control of insects Repellents are of value for the prevention of bites, especially in the case of persons who are sensitive to bites of the mosquito, fly, flea, chigger (Trombicula) and the tick Persons traveling in foreign countries and in tropical or subtropical areas should be instructed in the chemical control of insects This instruction is as important as the detailed inoculation program The activity of the repellent is limited to the area or areas protected and by its duration Repellents may be used in liquid or in cream form, or the clothing may be impregnated The repellents available now are materials of low sensitivity index

University of Cincinnati

rare instances keloid,[1] melanoma,[2] severe pyogenic infection,[3] amputation,[3] gangrene[3] and even death[3] have been reported as direct consequences of tattooing

Allergic reactions to the material used in tattooing can occur immediately or at any time during the existence of the tattoo Allergic reactions to mercury, usually used in the red part of tattoos, have been most frequently noted[4] The allergic dermatitis may either be confined to the tattoo or be generalized The allergenic mercurial compound causing the dermatitis need not be the mercuric sulfide (cinnabar) in the tattoo, but it can be any form of mercury which is used on the skin or internally

Local or systemic disease can be injected into the skin at the time of the operation The manifestations of the injected disease may appear at once or later, the time depending on the particular characteristics of the disease Leprosy,[5] tuberculosis,[6] syphilis,[7] tetanus,[4f] erysipelas[8] and chancroid[8] are reported to have been contracted in this manner

Clinical Notes

PROGRESSIVE DISSEMINATED COCCIDIOIDOMYCOSIS

WERNER W DUEMLING, M D
SAN DIEGO, CALIF

In 1892 Wernicke [1] and Posada [2] reported the first known case of coccidioidal granuloma Two years later Rixford [3] described the first case in the American literature At that time the causative agent was considered to be a protozoan, because of the resemblance of the indolent ulcers of the skin in this disease to those produced in animals by coccidia, the name of coccidioides was suggested for this agent In 1900 Ophuls [4] recognized and described the causative agent as a moldlike parasite which was readily cultured on various mediums It has been within the last decade that valley fever, the syndrome of influenza and erythema nodosum, has been attributed to coccidioides [5] This recognition of the primary infection has caused a considerable change in attitude toward the disease Coccidioidal infection, once considered a rarity when recognized only in the granulomatous stage, is now not uncommon, however, the extensive and unusual involvement in the following cases which came under our observation merits reporting in detail

REPORT OF CASES

CASE 1—A M R, a 32 year old Mexican Indian, entered the United States Naval Hospital, Treasure Island, San Francisco, on April 8, 1944, complaining of a painful right ankle and sores on his skin He was born in San Diego and prior to his enlistment in the Navy on Dec 13, 1943, had lived in San Diego county

On March 15, 1944, a nodule developed on his left forefinger and his right ankle became painful Several days later nodules appeared on the left cheek and on the right side of the forehead These nodules were at first small, reddish purple and smooth-surfaced but later became verrucous and elevated, with a purulent discharge

The physical examination revealed a small, thin man in no distress, with purulent verrucous nodules on the left forefinger, right side of the forehead and the left cheek (fig 1) There was widespread lymphadenopathy and a warm, tender, swollen right ankle The examination revealed no further abnormalities

3 Rixford, E A Case of Protozoic Dermatitis, Occidental M Times **8**.704, 1894 Rixford, E, and Gilchrist, T C Two Cases of Protozoan (Coccidioidal) Infection of the Skin and Other Organs, John Hopkins Hosp Rep **1** 209, 1896

4 Ophuls, W, and Moffitt, H C A New Mold (Formerly Described as a Protozoan Coccidioides Immitis Pyogenes), Philadelphia M J **5** 1471, 1900 Ophuls, W Further Observations on a Pathogenic Mold Formerly Described as a Protozoan, J Exper Med **6** 443 (Feb) 1905, Coccidioidal Granuloma, J A M A **45** 1291 (Oct 28) 1905

5 Dickson, E C Coccidioides Infection, Arch Int Med **59** 1920 (June) 1937, Valley Fever, California & West Med **47** 151 (Sept) 1937

The erythrocyte sedimentation rate was 30 mm per hour, and the white cell count was 7,750, with 6 per cent eosinophils The reaction in the coccidioidin skin test was positive Aspirated pus from fluctuant cervical lymph nodes contained the double-contoured highly refractive spores characteristic of coccidioidomycosis The early lesions became granulomatous, and new abscesses developed in the left knee, the left buttock, the left portion of the thorax and submental region The diagnosis was verified by culture, biopsy and guinea pig inoculation The lesions were treated by drainage and excision, and potassium iodide was given orally, with little or no improvement On May 5 the patient was given a course of penicillin extending over a seven day period and totalling 1,000,000 Oxford units, with no appreciable change Roentgenograms on August 23 revealed parenchymatous infiltration of the subclavian portion of the right lung and destruction of the bone of the left seventh rib, all previous roentgenograms had shown no abnormalities Treatment with coccidioidin vaccine, at first a stock supply and later an autogenous

Fig 1—*A*, noduloulcerative lesions of the face *B*, detail of lesion on left cheek, showing close resemblance to blastomycosis

vaccine, was started on July 18, 1944 and continued at two week intervals The patient continued to lose weight, became cachetic and debilitated and, on Jan 1, 1945, died

Abstract of Necropsy Protocol—Gross Findings Lungs The right pleural cavity contained 2,000 cc of pale yellow fluid flecked with fibrin The lower lobe of the right lung was atelectatic, while the apex revealed several small cavities from 1 to 5 mm in diameter, forming a honeycombed tissue surrounded by a solid white parenchyma These cavities were lined by a pale gray, granulating membrane No definite miliary or nodular granulomas were seen on gross inspection

The left pleural cavity was almost obliterated by fibrous adhesions The cut surface of the lung did not reveal any gross pathologic changes The tracheobronchial lymph nodes were enlarged up to 1 5 cm The cut section revealed extensive caseous and calcareocaseous destruction

The last group of reactions includes the appearance of local or systemic disease in tattoos after the tattoos have become a site of lowered resistance Brose[9] demonstrated that all portions of tattoos are more sensitive to blows, rubbing and external mechanical stimuli than is normal skin Belote[10] and others showed that tattoos alter the distribution of secondary syphilis The lesions were accentuated in and around tattoos except in the red (mercuric sulfide) portion, where the protective influence of the mercuric ion was greater than the effect of the foreign pigment in lowering the resistance of the area This paper records the first case known to me of chronic discoid lupus erythematosus occurring in a tattoo

Fig 3—Low power view of microscopic section taken from a lesion in the tattoo, showing histopathologic features in keeping with chronic discoid lupus erythematosus

REPORT OF A CASE

J C, aged 36, a white male truck driver, was tattooed on the lateral surface of the left arm in 1943 The tattoo healed after the initial reaction and showed no signs of irritation until November 1947 Then the red part of the tattoo began to itch and burn A dermatitis appeared in the red part of the tattoo in about a week. The patient stated that there was not any known cause for the symptoms

9 Brose Neue Tätowierungsphänomene, Dermat Wchnschr **84** 461-463 (April 2) 1927

10 Belote, G H Tattoo and Syphilis, Arch Dermat & Syph **18** 200-209 (Aug) 1928

Heart The pericardial sac was completely obliterated by firm, fibrous adhesions except for a linear pocket of thick pus along the left side of the heart Here the visceral and parietal layers were roughened by a thick, organizing, fibrinopurulent exudate which extended up over the base

Alimentary Tract The mesothelial surfaces of the mesentery and of the parietal wall were moderately studded with fine, white, glistening miliary lesions, of pinpoint

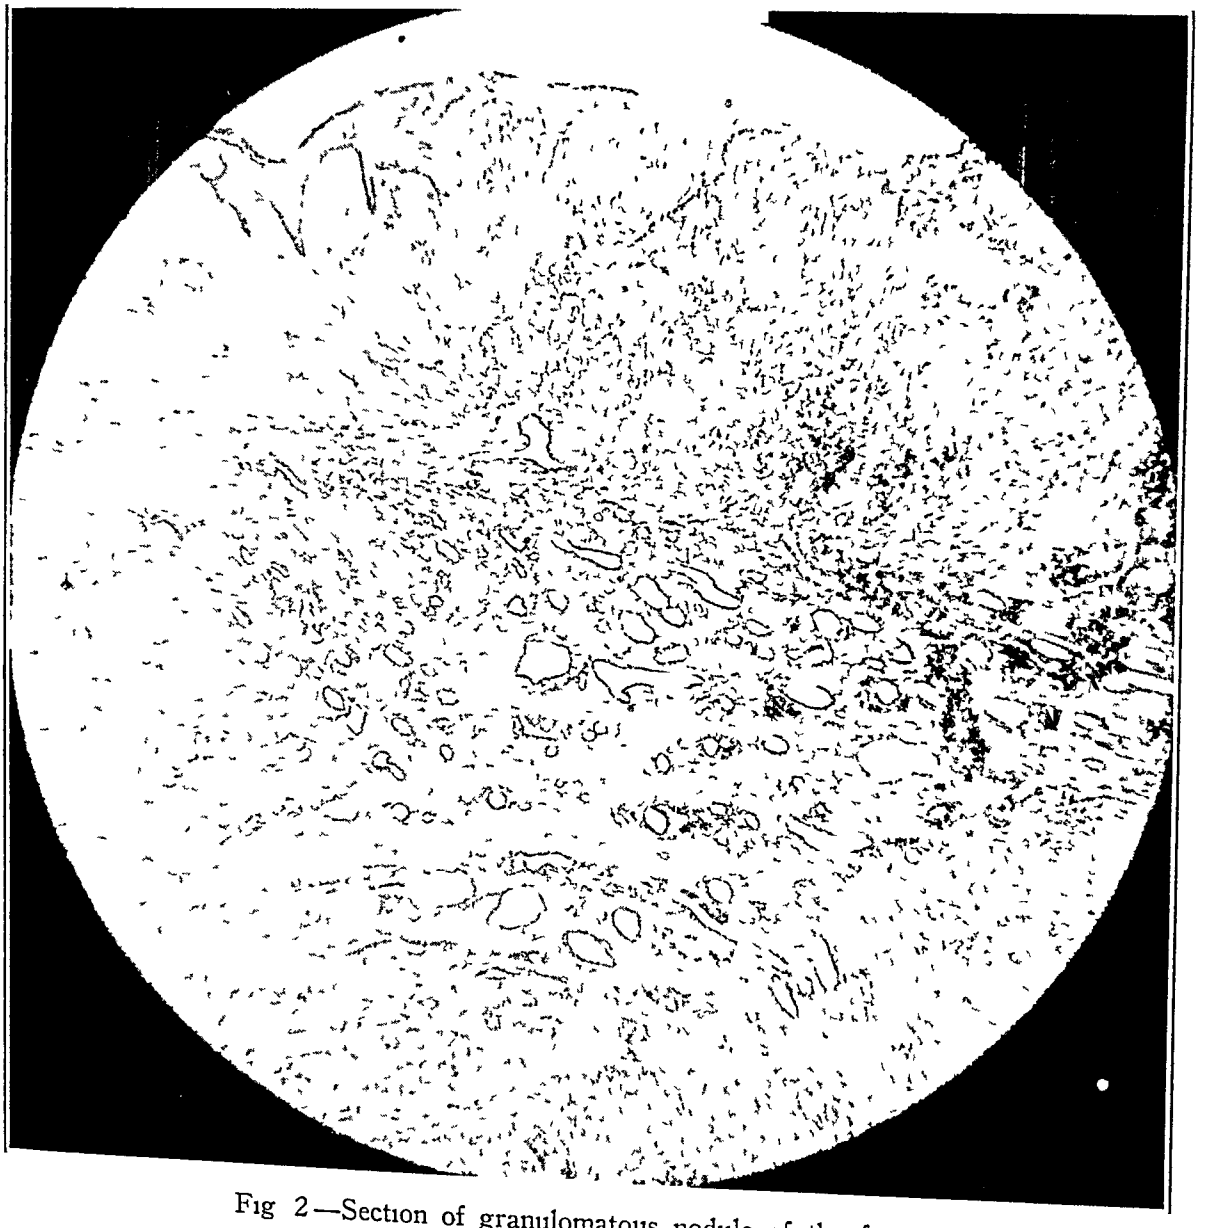

Fig 2—Section of granulomatous nodule of the face

to pinhead size Short fibrous tags were found along the mesenteric attachment and over the leaves of the mesentery

The esophagus was grossly normal except for a longitudinal lesion of 7 by 2 mm located on the anterior wall 7 5 cm below the rima glottidis The stomach had a pale pink and somewhat atrophic mucosa Three small, ulcerated outpouchings of the mucosa were located in the magenstrasse, 4 cm proximal to the pylorus These were about 3 to 4 mm in diameter, with smooth bases and borders The overlying serosa was thickened with fibrous tags The intestines

or the eruption This development was accompanied by a similar dermatitis on the face, which also itched and burned In March 1948 the patient had scattered, pea-sized to dime-sized, dry, round, erythematous, pruritic papules covered with an adherent carpet-tack-like scale on the face and in the red part of the tattoo There were about fifteen lesions on the face and four in the tattoo Reactions in the Mantoux test and in serologic tests for syphilis were negative A roentgenogram of the chest and other laboratory studies showed normal conditions Biopsy specimens from lesions on the face and from the tattoo showed histopathologic features which were in keeping with the diagnosis of chronic discoid lupus erythematosus All lesions seemed to respond to bismuth subsalicylate in oil given intramuscularly On two separate occasions the eruption showed an acute flare-up when the face was exposed to sun and wind for about three hours All lesions flared, even though those in the tattoo were protected by a shirt and a heavy leather jacket

SUMMARY

A case of chronic discoid lupus erythematosus with characteristic lesions on the face and in the red portion of a tattoo on the left arm is reported Wind burn and sunburn caused the eruption to flare simultaneously on the face and arm even though the eruption on the arm was protected by a shirt and heavy leather jacket

(Footnotes continued on next page)

also contained similar small, shallow, ulcerated areas Their margins were formed by a delicate, pale, granular membrane, the overlying serosa was thickened by fibrous tags A solitary lesion was found in the duodenum, while about twenty-four such lesions were seen in the cecum and ascending colon Most of the lesions were 2 by 4 mm, with their long axes at right angles to the long axis of the bowel

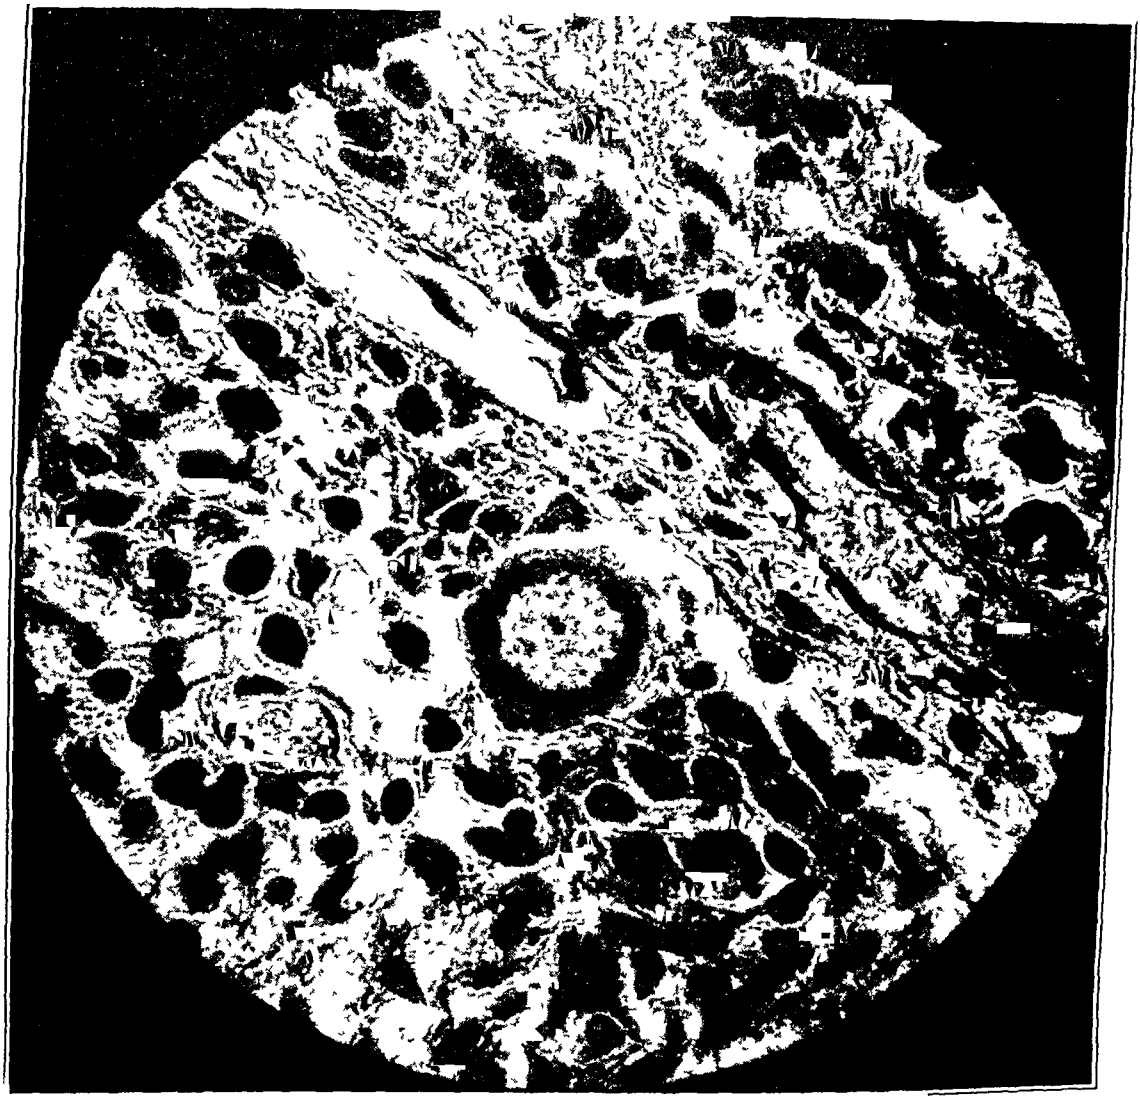

Fig 3—High power view, showing a characteristic mature endosporulating spherule

Osseous System The only significant bone lesion was a small area of osteomyelitis of the left seventh rib The cortex was irregularly thickened for a distance of 7 mm proximal to the medullary lesion on the pleural surface

Microscopic Observations (figs 2 and 3) In general the lesions were typical granulomas with numerous coccidioidal spherules The larger lesions showed tubercle formation, with central caseation The spherules were present free in the proliferating reactive border and within the Langhans giant cells The granulation tissue was composed of capillaries, proliferating endothelial cells and young collagen

lentigines,[9] and dermatitis herpetiformis.[9] There have also been reported several cases of allergy of similar type and onset.[10]

The following case of alopecia areata beginning at the same time on identical areas of the scalp in monozygotic twins aroused our interest

REPORT OF A CASE

Robert L. and Raymond L., 11 years of age, presented themselves to the Dermatology Clinic, City of Detroit Receiving Hospital, on Oct. 31, 1947, with the complaint that each had a bald spot on his head. Their mother stated that

Showing similarity in appearance of the twins and small areas of alopecia areata in identical locations on the right side of the occiput.

these spots had been first seen by her on the same day in June 1947, that to the best of her knowledge both had appeared at the same time and that she was sure that they had not been present the previous week.

connective tissue elements, a heavy infiltration of plasma cells and lymphocytes, tissue mast cells, mononuclear phagocytes with cell detritus and an occasional polymorphonuclear leukocyte Varying numbers and sizes of coccidioidal spores were scattered throughout this granulomatous tissue Many contained endospores, but in some instances they were devoid of these and appeared as empty cysts with double-contoured envelopes The cells of the tubercles were arranged in a

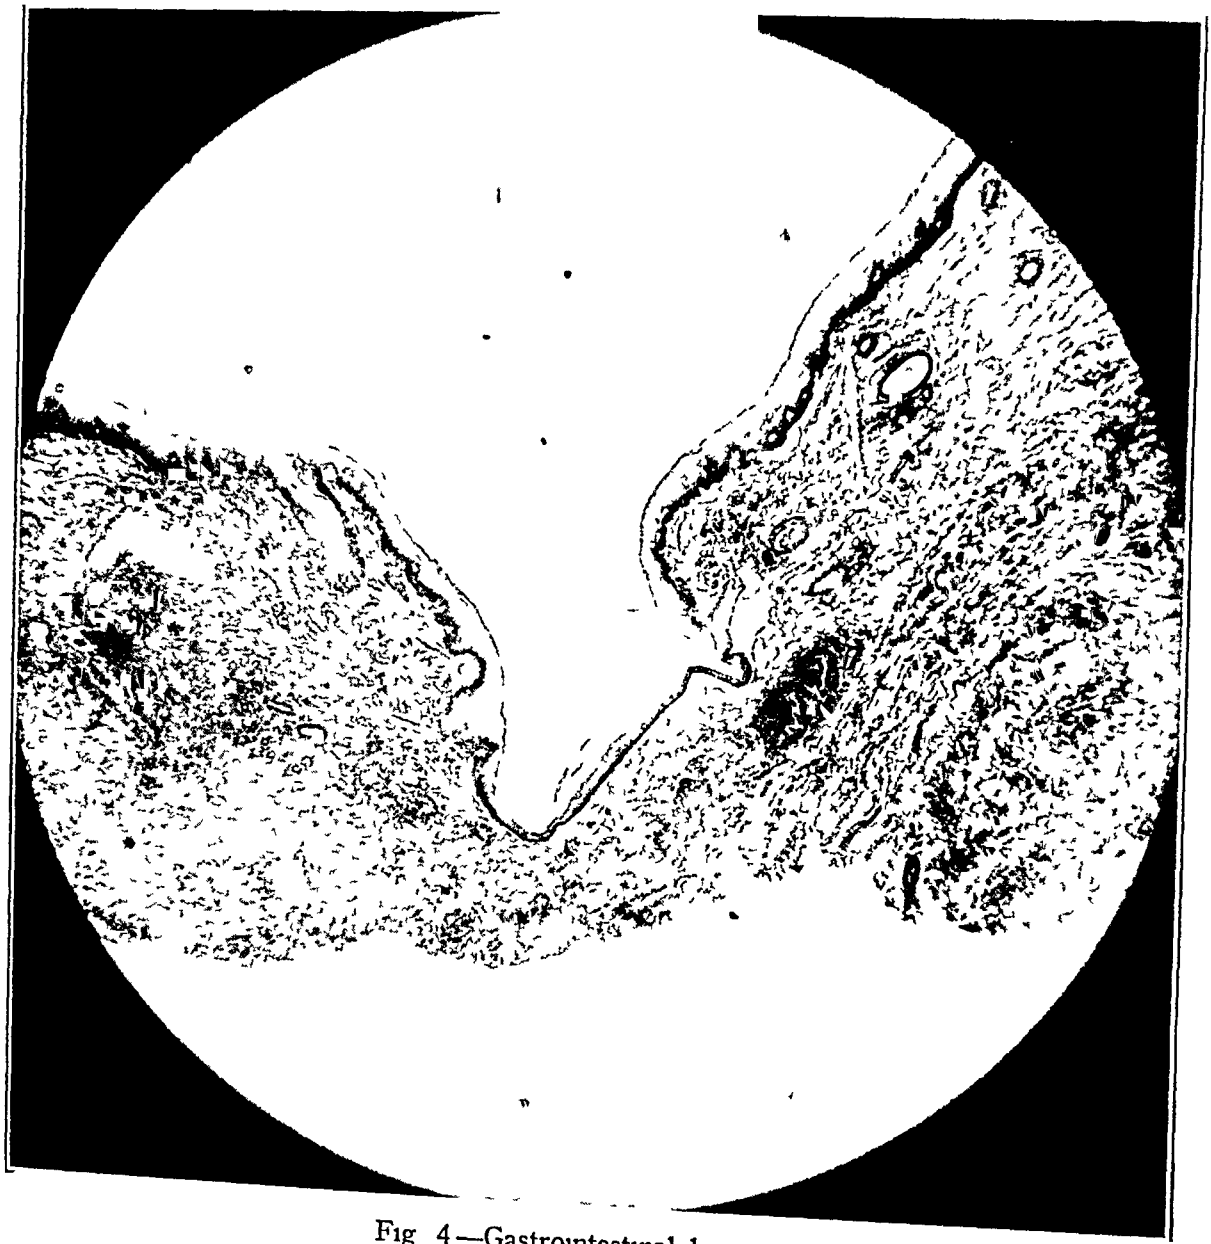

Fig 4—Gastrointestinal lesion

somewhat concentric, onionskin lamination The gastrointestinal lesions (fig 4) showed similar ulcerative granulomatous pathologic changes, involving the mucosa, submucosa and, to a lesser extent, the muscularis

Case 2—E A H, a 20 year old American Negro, was admitted to the surgical service of the United States Naval Hospital, San Diego, Calif, on Jan 26, 1946, complaining of pain in the right upper portion of the abdomen Prior to the completion of comprehensive laboratory examinations he constituted an interesting diagnostic problem, inasmuch as the differential diagnoses listed, among other

The family consisted of the mother, the father and 4 children No other member of the family had or ever had had a similar type of loss of hair Both patients had had measles and pertussis at 18 months of age Robert had had chickenpox when he was 6 years old, but Raymond had not There was no history of other previous illnesses

On examination the boys were strikingly similar in appearance, with the same shade of hair and with the same characteristics in regard to ears, teeth, nose and mouth In all zones of the iris of both patients there was the same type of pigmentation and distribution[11] Both boys exhibited a small area of typical alopecia areata in identical locations on the right side of the occiput approximately 2 by 0 75 cm Below each lesion there were three smaller areas of thinning of the hair but no complete loss in any place except those previously mentioned

Repeated examinations of the scalp under the Wood light revealed no fluorescence in the case of either boy Repeated cultures were negative for tinea capitis The hair appeared normal on direct microscopic examination Observations in blood counts (red cells, white cells and differential), as well as in urinalysis and serologic examinations, were all essentially normal

COMMENT

In a review of the literature for the past several years only 1 case of alopecia areata in twins was found,[12] and that case was somewhat different from the one here presented in that the lesions were not identical and did not appear simultaneously

Several theories have been advanced as to the cause of alopecia areata, but the exact etiology is unknown No single theory will account for all cases of the condition

In presenting this interesting and rather unusual case no attempt is being made to interpret the findings, and it is not our intention to try to prove or disprove any of the theories that have been advocated to date Rather, the case is presented purely as a dermatologic curiosity

SUMMER PRURIGO

Report of a Case Controlled by Diphenhydramine (Benadryl®) Hydrochloride

HARRY W WOOLHANDLER, M D
PITTSBURGH

Summer prurigo is at best an incompletely understood entity While it is generally accepted that hypersensitivity to sunlight produces the eruption, the exact wavelength responsible has never been definitely established Experimental

From the Section of Dermatology, University of Pittsburgh School of Medicine

things, syphilitic hepatitis, subacute appendicitis, low grade hepatitis with multiple abscesses, parasitic infection of the intestine with perforation, trichinosis, secondary syphilis, nephrolithiasis, Loffler's syndrome, eosinophilic leukemia and pneumonitis

On January 24, epigastric pain, which lasted for about two hours, developed after meals On January 25, the patient had pain in the lower right anterior portion of the chest, but no dyspnea or infection of the upper respiratory tract, and afterward a persistent dull, aching pain appeared on the right side at the costal margin The following day, the patient first noticed two small papules, one on the midback and one over the epigastrium

The physical examination showed essentially normal conditions except for moderate tenderness in the right upper quadrant at the costal margin The abdomen was soft, and no masses or organs were palpable The chest appeared clear on auscultation and percussion Over the midepigastrium and midback there were two small, suppurating nodules

Fig 5 (case 2) —Showing lesions of lips and chin from which Coccidiodes immitis was isolated

The erythrocyte sedimentation rate was 18 mm per hour, and the white cell count was 11,250, with 24 per cent eosinophils Subsequent blood counts all revealed an eosinophil count averaging about 14 per cent Repeated coccidioidin skin tests had negative reactions Reactions to the Kahn and Kline tests were initially positive, but to the Kolmer, Wassermann and repeated Kahn tests they were negative Biopsy of the nodule over the upper portion of the abdomen revealed numerous double-contoured, highly refractive spores characteristic of Coccidioides immitis Roentgenograms of the chest showed increased mottled markings of the central and lower central lung fields

The patient was put on a supportive regimen but continued to have a low grade fever He acquired new cutaneous lesions (fig 5) similar to the original two and rapidly began to fail as the pulmonary infection progressed C immitis was isolated from the purulent discharge of the ulcerating lesions He was given whole blood transfusions, 100 cc of protein hydrolysates (parenamine®) daily and 15 drops of

reproduction of this dermatosis has been accomplished with ultraviolet rays, ordinary sunlight, sunlight passed through window glass, yellow and red rays of longer wavelength only and even alpha and gamma rays [1] Attempts at desensitization have generally been unsuccessful, and, except for symptomatic treatment and avoidance of sunlight, no therapeutic measure of merit has been described Thus, the dramatic response to diphenhydramine hydrochloride (benadryl hydrochloride®) in a recently treated patient appears worthy of reporting

REPORT OF CASE

A 5 year old white girl was first seen by me on April 9, 1947, with an eruption of the cheeks and nose of four days' duration History obtained from the mother indicated that the patient had previously had a similar eruption lasting from June 1946 to October 1946, which initially had involved the face and the forearms At that time the patient had been seen by the family physician, who had prescribed daily exposures to sunshine After a few days of such exposures the eruption spread to the arms, legs and chest, with the lesions becoming moist and crusted for the first time There was no response to local applications, but in early October the eruption healed spontaneously The child's skin then remained entirely clear until April 5, 1947, when the eruption reappeared

Examination on April 9 revealed an eruption involving the cheeks and the nose and consisting of grayish red plaques, which on closer inspection were seen to be made up of closely set papules with adherent scales The lesions on the nose were entirely discrete, while those on the cheeks had coalesced into small plaques A diagnosis of summer prurigo was made, and on April 17 the patient was presented before the Pittsburgh Dermatologic Society, where this diagnosis was accepted by all except one member, who stated the belief that the disease was a dry staphylococcic infection

On April 9, the date of the first visit, the patient's mother was admonished to keep her out of direct sunlight, and a paste containing 3 per cent ichthammol (ichthyol®) was prescribed However, the mother permitted the child out in the sunlight as usual, and three days later the eruption had spread to the forehead and forearms, the original areas of involvement on the cheeks and nose having become more extensive A bland paste containing menthol, phenol, boric acid, zinc oxide, petrolatum and rose water ointment was substituted for the ichthammol paste and elixir benadryl hydrochloride® (a preparation containing 0 25 Gm diphenhydramine hydrochloride [benadryl hydrochloride®] in an elixir containing alcohol, glycerin and water, with sugar, flavoring oils and added color, in each 100 cc) 1 fluidrachm (3 7 cc) three times daily, was prescribed On April 17 the eruption showed no appreciable change, but on April 24 there was striking improvement, the face being almost entirely clear and the eruption on the forearms improved When the patient was next seen, on May 8, the skin of the face was entirely normal and the eruption of the forearms was barely discernible On June 7 no evidence of the original eruption could be seen, but a small area of involvement was found in the sternal region The child's mother admitted having permitted the girl out in the sun during a recent hot spell with no clothing except bathing trunks A promise was then exacted that the child would at no time be permitted outside with less clothing than a dress The sternal involvement

1 Becker, S W, and Obermayer, M E Modern Dermatology and Syphilology, ed 2, Philadelphia, J B Lippincott Company, 1947, p 291

a saturated solution of potassium iodide three times daily On March 26, he was started on a course of penicillin, receiving 50,000 units every two hours for a total of 3,600,000 units His downward course progressed, and on April 2, just after completion of the course of penicillin, he began to exhibit signs and symptoms of cerebral involvement, which terminated in meningitis Spinal puncture revealed a grossly clear fluid which, on microscopic examination and later on culture, revealed C immitis On April 7, the patient died Postmortem examination revealed miliary coccidioidomycosis of the meninges, lungs, spleen and lymph nodes and a large granuloma of the sternum and the right second rib anteriorly There were many extradural abscesses The microscopic examination of all the tissues involved confirmed the gross findings, revealing typical lesions packed with C immitis

SYMPTOMATOLOGY AND CLINICAL COURSE

The infection assumes a wide variety of manifestations, ranging from the asymptomatic variety to the frequently fatal disseminated form, and can be best understood and discussed under the following classification proposed by Smith [6] Clinically it may be divided into three forms primary, intermediate and progressive

Primary Stage—In the majority of cases in the endemic areas, the onset of the initial infection may pass unrecognized or be interpreted as a mild infection of the respiratory tract This was probably the situation in 1 of our cases (case 2), in which the patient gave a history of an infection of the respiratory tract two months prior to his admission to the hospital On the other hand, the respiratory symptoms may be prostrating and more prolonged, accompanied by malaise, substernal pain in the chest, cough, night sweats and nasopharyngitis A small percentage of patients suffer a recurrence of fever in from three days to three weeks, associated with erythema nodosum or erythema multiforme, regarded as an expression of the allergic state While the disease in this stage is usually self limited, it must be remembered that a very small undetermined percentage may steadily progress to the disseminated form

Intermediate Stage—With a few exceptions the pathologic changes and symptoms in this stage are strikingly like those found in tuberculosis The findings may vary from the mildest to massive consolidation, cavity formation or scattered lesions resembling miliary tuberculosis, and the course may likewise vary in direct relation to the severity of the involvement Although cavity formation may occur without subjective symptoms, most patients complain of pleuritic pain and a productive cough Unlike the situation with tuberculosis, even patients with the most extensive pulmonary involvement recover, and the symptoms in relation to the amount of involvement are less severe than in tuberculosis Treatment is entirely symptomatic, with the elevation of the sedimentation rate the best guide for clinical management

Progressive or Disseminated Form—Fortunately the incidence of this form of the disease, which carries a very high mortality, is very low The incidence is definitely higher in the heavily pigmented races, of which both patients whose cases form the basis of this report were members The symptoms and the course vary with the organs involved, and the disease may terminate in death in a period of from a few weeks to a year In 1 of our cases the disease was more fulminating in type, terminating with meningitis in about two and one-half months, while in the other the patient lingered on for nine months Involvement of the bones, joints,

6 Smith, C E Coccidioidomycosis, M Clin North America **27** 790 (May) 1943

healed in a few days, and no further relapses occurred during the entire summer Use of diphenhydramine hydrochloride was stopped on October 15, and there was no recurrence of the eruption up to Feb 15, 1948

COMMENT

An attempt was made during the management of this case to obtain consent to temporary discontinue use of the diphenhydramine hydrochloride (benadryl hydrochloride®), in order more definitely to establish the role of this drug in treatment of summer prurigo The mother's refusal prevented this or any other experiments from being carried out Nevertheless, I feel that the evidence, while presumptive, indicates that diphenhydramine hydrochloride was responsible for the control of this eruption At no time was any other medicament, except the bland paste mentioned, employed and the child was apparently exposed to direct sunlight regularly during the entire spring and summer That the diagnosis was probably accurate is attested to by the almost unanimous agreement of more than twenty dermatologists Further use of this drug in treatment of summer prurigo is definitely indicated, similar results would, of course, suggest that histamine plays a role in the causation of summer prurigo

SOLID CARBON DIOXIDE AS AN ANESTHETIC IN ELECTRODESICCATION OF CUTANEOUS BLEMISHES

ALEXANDER BREGMAN, M D
Associate Dermatologist, Englewood Hospital, Englewood, N J
EDGEWATER, N J

The electrodesiccation of cutaneous blemishes necessitates the use of local anesthesia because without it the procedure is too painful to be acceptable to patients Of the two methods of producing local anesthesia, namely, ethyl chloride freezing spray and infiltration with procaine or similar drugs, the local infiltration anesthesia is the more practicable Ethyl chloride spray is impracticable for two reasons It is inflammable, and thus unsafe for use in the presence of a spark, and the anesthetic effect wears off by the time the ethyl chloride has evaporated In using electrodesiccation for such lesions as pigmented moles or common warts in the region of the cartilaginous portion of the nose it is sometimes difficult for one to employ an anesthetic acting by local infiltration because of the close proximity of the underlying cartilage and lack of loose subcutaneous tissue which would allow infiltration with the anesthetic

Solid carbon dioxide used for its anesthetic effects works well in such situations It possesses the advantages of other types of compounds producing local anesthesia without exhibiting their drawbacks, and is less objectionable to the patient It is not inflammable, and it is of more lasting effect than is ethyl chloride spray, the latter characteristic being accounted for by the fact that ethyl chloride produces a temperature of about —31 F, whereas with solid carbon dioxide a temperature as low as — 110 F can be obtained

Although any type of machine for making solid carbon dioxide can be used satisfactorily for this purpose, I employ the Kidde dry ice® apparatus The whole

lungs, mediastinum and lymph glands is common, with the frequent development of verrucous and granulomatous nodules of the skin and subcutaneous cold abscesses The development of meningitis is evidence of wide dissemination and may occur with or without extensive visceral involvement The course of the meningitis is not unlike that of tuberculous meningitis, and, coincident with mental confusion in 1 of our cases, spherules of C immitis were demonstrated in the spinal fluid Gastrointestinal involvement is said not to occur because of digestion of the spherules, but Greaves [7] reported lesions in the small intestine and Ruddock [8] made the diagnosis by peritoneoscopy in a patient thought to have tuberculous peritonitis One of our patients (case 1) presented multiple lesions of the gastrointestinal tract, extending from the esophagus to the transverse colon They consisted of small, ulcerated outpouchings of the mucosa, 3 to 4 mm in diameter, with smooth bases and borders The margins of the ulcers were formed by a delicate, pale, granular membrane, the overlying serosa was thickened by fibrous tags The long axis of most of the lesions was at right angles to the long axis of the bowel

Treatment.—We are not concerned with the treatment of primary or intermediate coccidioidomycosis in this paper Suffice it to say that bed rest and symptomatic therapy will eventuate ultimately in clinical recovery, except in those cases with extensive cavitation, in which pneumothorax is required It is the progressive variety, of which the cases herewith presented are examples, that have so far been unaffected by a wide choice of remedies The drugs which have been of some value in other deep-seated mycoses, such as thymol, iodides, copper and antimony compounds and potassium tartrate, have uniformly failed to influence the course of the disease Penicillin offered nothing in our hands and has been reported by others [9] as ineffective Great hopes have been entertained for vaccines, but both the use of a stock and autogenous vaccine over a long period of time in increasing doses has been of no avail In order to rid the patient of large reservoirs of organisms which would otherwise be disseminated, all accessible granulomatous nodules were removed Roentgen therapy has been of no benefit, except to flatten exuberant granulomas The outlook in the progressive form of the disease must still be regarded as hopeless

EPIDEMIOLOGY

The epidemiology of coccidioidomycosis has become increasingly important because of the large numbers of men from all parts of the country brought into the endemic areas for training purposes during the past war and because of definite evidence of spread of the endemic areas For a long time after its first recognition, cases were reported only in those living in or near the great central valley of California It was not until 1920 that the first case east of the Mississippi was reported, and in the next decade there were accounts of sporadic cases in the Middle West and the eastern states A recent study by Smith [6] now reveals endemic areas occupying the great central valley of California and extending into southern California, all of Arizona, southern Nevada and southern Utah, probably parts of Idaho, all of New Mexico, western Texas and at least northern Mexico

procedure of producing anesthesia by freezing does not take more than a couple of minutes I apply the solid carbon dioxide pencil for ten seconds with moderate pressure and then proceed with electrodesiccation

After having used this method on a few patients with lesions in the nasal region and having proved to my complete satisfaction its feasibility and practicability I began to employ it in producing anesthesia on other parts of the body whenever electrodesiccation was indicated—in treating small isolated lesions of various natures I submit this method in the expectation that others may try it to determine the possibilities of this simple and practical way of treating cutaneous blemishes

ALLERGY TO WAX CRAYONS

Report of a Case

MIRIAM LUTEN, M D
PORTLAND, ORE

In 1947, two reports of cases of poisoning by wax crayons appeared in the literature The first one, by Jones and Brieger,[1] described a child in whom symptoms of severe paranitraniline poisoning developed as a result of the patient's eating red and orange crayons In the second report, Clark [2] told of the case of a child who acquired methemoglobinemia from eating yellow and orange crayons Schwartz, Tulipan and Peck [3] stated that school teachers may acquire dermatitis of the terminal ends of the thumb and index fingers from the dye in colored crayons They found that among 81 workers in refineries manufacturing paraffin 19 had boils or acne on their arms and hands They found that oil and wax acne differs from acne vulgaris in that the eruption in oil and wax acne is oftener found on the body and legs than on the face, which situation they attributed to the plugging of the orifices of the hair and the sebaceous follicles, with formation of comedos which become secondarily infected They expressed the opinion that the percentage of wax warts, acne and pustules decreases in direct proportion to the purity of the paraffin handled and that workers handling the white, refined product are almost free from these conditions

REPORT OF CASE

S S D, a 7 year old girl, came to the office, complaining of sties which had been present almost continuously for four years For the previous two years she had had severe itching of the axillas and the buttocks, followed by many furuncles in these regions Treatment had consisted of stock and autogenous vaccines, stannoxyl® (a preparation containing 42 5 per cent metallic tin and 7 5 per cent tin oxide) and general hygienic measures, all without benefit There were no refractive errors

3 Schwartz, L, Tulipan L, and Peck, S M Occupational Diseases of the Skin, ed 2, Philadelphia, Lea & Febiger, 1947, pp 240, 243 and 858

density visualized in the left apical region superimposed on the posterior border of the third left rib, with the suggestion of a drainage band extending to the left *hilus*

Histologic section revealed acanthosis with edema of the prickle cell layer The corium is edematous and contains a cellular infiltrate composed of lymphocytes, plasma cells and leukocytes Deep in the corium there are numerous double contour bodies with a few giant cells

DISCUSSION

DR. OLIVER S ORMSBY I had been practicing only about a year when I was called to see a patient who was supposed to have tuberculosis A man of middle age had lesions on the face and on the extremities The lesions on the face were fairly typical of blastomycosis, but the lesions on the extremities were very different In those areas there were subcutaneous nodules, abscesses and ulcers, with pus oozing out of the lesions I took a specimen to the office and demonstrated Blastomyces The patient was very ill and died shortly thereafter At autopsy I was able to demonstrate Blastomyces in the lungs, liver, spleen, kidneys and bones That was the first case on record in which there was systemic blastomycosis involving all the tissues

During the next three or four years I saw 4 or 5 more cases, and it was shown that this organism attacks every tissue in the body At autopsy the doctor in charge pricked his finger, and within a little while blastomycosis developed in that finger, and within two or three months he had systemic blastomycosis In our early experience practically 100 per cent of the patients died Since that time a certain percentage recover

DR M J REUTER, Milwaukee One of our residents checked over our records on systemic blastomycosis and was able to find 38 cases of the generalized type Of this number he was able to trace 26 One patient is still alive after ten years and another is alive after two years

Paraffinoma Presented by DR T CORNBLEET and (by invitation) DR D COHEN and DR J GRAFFIN

C H, a white woman aged 63, about twenty-five years ago, had wax injected into both cheeks and the forehead for cosmetic purposes At present she is in a medical ward at the Cook County Hospital with arteriosclerotic heart disease and possible endocrine disturbance Examination revealed a firm mass, 5 cm in diameter, in both cheeks, and a smaller one between the eyebrows The overlying skin is bound down to the masses and is bluish red

The Kahn reaction of the blood was negative The urine was normal The electrocardiogram reveals myocardial damage Histologic sections from the mass in the cheek are presented

DISCUSSION

DR OLIVER S ORMSBY I saw one of those cases in my early experience It was only the second case that had been seen in this country My co-workers and I were fortunate enough to get a section which showed the typical sievelike arrangement where the paraffin entered the connective tissue This woman was very handsome, and she decided to have some dimples put in each side and to have some wrinkles taken out A half dozen large tumors developed A plastic surgeon removed them, and the result was very good At a later date we saw tumors from paraffin oil used for injection

DR S J ZAKON There are a lot of Romansky injections being given in the treatment of syphilis and other diseases with penicillin in large doses I have seen

a number of severe reactions in the buttocks following such injections The reactions would subside in a couple of weeks I wonder whether fifteen or twenty years from now one will see lesions similar to paraffinoma due to Romansky injections

DR STEPHEN ROTHMAN With vegetable oil and fatty acids paraffinoma does not occur Paraffinoma occurs exclusively with hydrocarbons I doubt whether white wax would produce paraffinoma, because such wax is composed of fatty acid

DR THEODORE CORNBLEET It is my feeling that one need not expect the same accidents to happen from the Romansky formula as from paraffin itself With paraffinoma there is no initial reaction, whereas with white wax one commonly finds a reaction in the tissues Originally, I tried to arrange to have a fluorescent light to detect the presence of the paraffin, which shows a Swiss cheese structure

Sporotrichosis Involving the Face and All Extremities Presented by DR MICHAEL H EBERT and (by invitation) DR N L BAKER

Acute Disseminated Lupus Erythematosus in a Man Aged 37 Years Presented by DR MICHAEL H EBERT and (by invitation) DR N L BAKER

A Case for Diagnosis (Eruption Due to Drugs? Hemorrhagic Lupus Erythematosus? Toxic Purpuric Disease of Undetermined Origin?) Presented by DR S ROTHMAN and (by invitation) DR L RUBIN

Keratosis Follicularis (Darier?), Improved After Ingestion of Butter in Large Quantities Presented (by invitation) by DR H H RODIN

Recurrent Alopecia Areata Presented by DR E M SMITH JR

D D, a white boy, aged 7, rather small for his age, has a recurrent patch of alopecia areata involving the vertex and the strip down the center of his scalp toward the front This condition has occurred every September or October for the past five years and has run a course of about two or three months The configuration of hair loss is practically the same, and there is a complete clearing up of the condition between times

DISCUSSION

DR STEPHEN ROTHMAN I thought that definitely the boy had trichotillomania and that he had done a good job for himself

DR E M RUSTEN, Minneapolis I have a patient who is a resident in a tuberculosis sanatorium In 1928 he had pulmonary tunberculosis with bilateral effusion and rather extensive alopecia areata The pulmonary tuberculosis was controlled by sanatorium treatment, and he had a recurrence of hair growth About a year ago he had a recurrence of the pulmonary disease and again had alopecia areata His pulmonary disease is now improving, and his hair has also returned

DR JAMES R WEBSTER When I first saw the patient this afternoon I had the impression that the condition was trichotillomania, but on further examination concluded it was alopecia areata

After the suggestion that this condition could be due to allergy, the mother could recall only one material that the child had used continuously during this time At 3 years of age, she had started playing with wax crayons every day Patch tests of wax crayons and fatty extracts of house dust and dog hair made on the skin around the axillas were indeterminate When crayons were taken away from the child, she was free from sties and boils for two and one half weeks, the longest period in the past four years She was given a crayon for two minutes Within one-half hour, her eyelids became red, and sties appeared on the lids by the next morning Perma® crayons, which the manufacturer stated are made by an entirely different process from that used in making the crayola,® produced sties after similar exposure During the succeeding months, infections on the lids followed the child's handling of pictures colored by other children and contact with candles Colored pencils, protected by wood covers, were tolerated for a short time only

Four trials were made with a piece of wax without dye, which was furnished by the manufacturer After one of these trials, a small sty appeared Smears made from the draining pustules contained diplococci The last trial with both uncolored and colored wax, one year later, caused only a generalized pruritus but no sties

The only local therapy used was tyrothrycin, which the mother believed shortened the duration of the lesions

Throughout the summer months, when the child was not in school or exposed to wax crayons, she remained free from cutaneous lesions, except for one episode in which a severe edema of the eyelids followed playing in weeds This edema disappeared almost at once when the child's face was washed Scratch tests at this time showed strong reactions to the pollen of English plantain

SUMMARY

A case is reported in which sties, furuncles and pruritus repeatedly followed exposure to wax crayons

919 Taylor Street Building (5)

Results of examination of the bone marrow obtained by puncture of the sternum were not diagnostic It showed a decreased cellularity (hypoplasia) with good myeloid distribution, moderate eosinophilia and normal megakaryocytes

During the three weeks' stay at the hospital the patient's condition has remained unchanged A consultation was held with the thoracic surgeon concerning the tumor in the left anterior mediastinum A tentative diagnosis of teratoma or echinococcus cyst was made and exploration advised

DISCUSSION

DR DAVID BLOOM This eruption resembles sarcoid as seen in white persons It would be of interest to study the effect of calciferol in this case

DR LOUIS CHARGIN What is the pathologic report in this case?

DR FRANK E CROSS Clinically the lesion in this case is sarcoid, in spite of the lack of confirmation on histologic study It is possible that the biopsy specimens were taken from nonspecific sites Another biopsy specimen should be taken from a characteristic lesion and examined by a dermatopathologist

DR MAX BERKOVSKY Three biopsy specimens were taken and examined by the general pathologist at the Metropolitan Hospital and Dr Hyman at the New York Post-Graduate Hospital At no time could one justify the diagnosis of sarcoid on histologic study The reaction to the tuberculin test (1 10,000) was negatives Roentgenograms of the bones showed no abnormalities Roentgenographic examination of the chest revealed a mass which the surgeon said was a dermoid cyst in the anteriomediastinal space

DR. PAUL GROSS What has been done to rule out tuberculosis?

DR MAX BERKOVSKY No tuberculoid tissue was found on histologic examination There is nothing to warrant a diagnosis of leprosy

NOTE—The mediastinal tumor was removed by operation, and the histologic examination revealed a thymoma Subsequent histologic studies of cutaneous nodules by Dr W Sachs showed characteristic observations of lymphatic leukemia

Reticulum Cell Sarcoma Presented by DR DAVID B BALLIN

M M, a man aged 44, was previously presented before the New York Dermatological Society on Feb 25, 1947, by Dr Fred Wise, with the following note Additional data, such as results of the pathologic study of the left epitrochlear lymph node excised, roentgenogram of the chest, general medical examination, sternal puncture and electroencephalogram will be reported later

The patient is presented to show the rapid regression after 1 skin unit of roentgen rays (450 r) and to report the results of laboratory studies A hemogram taken on February 20 showed 5,160,000 erythrocytes, 1 8 per cent hemoglobin and a color index of 1 05 There were no eosinophils The results of sternal puncture and examination of the lymph node excised from the left epitrochlear region were reported as normal

Examination on April 16 revealed considerable regression in the satellite lesions about five weeks after the biopsy specimen was taken, but there was no diminution in the size of the main growth On April 3 1 skin unit of roentgen rays filtered through 1 mm of aluminum (450 r) was applied to the main lesion and about

Feb 20, 1947

Lymphoblastoma, Tumors on the Forehead and Postauricular Subcutaneous Nodules Presented by DR MAX B KAMPF

Granuloma Annulare of the Legs with Keratotic Lesions Presented by DR LOUIS CHARGIN

Purpura Annularis Telangiectodes? Radiodermatitis? Hemostasis Dermatitis? Presented by DR PAUL GROSS

E B, a white woman aged 54, has had recurrent ulcerations on the feet for the past ten years In 1940 she was admitted to the Hospital for Joint Diseases because of multiple ulcers After the ulcers had healed many atrophic areas were found on the skin of both feet On the periphery of the atrophic patches were many bright red purpuric papules and telangiectases The diagnosis of purpura Majocchi was considered at the time, but the patient did not return for further treatment In October 1946 she was again hospitalized At that time large ulcers were present below the external and internal malleoli and on the dorsum of the right big toe Small ulcerations were also present on the dorsal and lateral surfaces of several toes of the left foot In addition, she had a seborrheic dermatitis of the nasolabial folds and eyebrows

The prothrombin time was increased to 30 seconds, and there was secondary anemia On October 16 the sedimentation rate was 70 mm in 45 minutes, on October 28, 45 mm and on, November 7, 15 mm The cholesterol content of the blood was 319 mg per hundred cubic centimeters, of which 30 per cent was free cholesterol and 70 per cent esterified cholesterol The thrombocyte count was normal The result of a tourniquet test for capillary fragility was positive The result of the Peck test with moccasin venom was positive on the forearm, thigh and the affected area

Treatment consisted of complete bed rest, applications of wet dressings with acriflavine and later of nitrofurazone ointment The patient was given ascorbic acid, 500 mg a day, vitamin B complex, folic acid, ferrous sulfate, and menadione The ulcers healed rapidly, and the patient was permitted to leave the bed for about an hour a day After two days of this regimen there developed purpuric macules and dark red puncta around the atrophic scars Some of these lesions changed into small necrotic ulcers the size of a pinhead

Since Dec 26, 1946, the patient has been receiving biweekly injections of moccasin snake venom No purpuric lesions have appeared recently, but there developed a small ulcer at the base of the left big toe

2 inches (5 cm) beyond When the patient was seen on April 15 the growth was entirely flattened out, so that it was only slightly elevated above the surrounding skin

Lichen Planus, Lichen Nitidus Presented by DR JOSEPH L MORSE

R S, a boy aged 7 years, was first seen at the Hospital for Joint Diseases with a generalized fine branny desquamation The mother stated that about three weeks previously the child had a generalized rash accompanied with fever A diagnosis of postscarlatinal exfoliation was made Urinalysis at that time showed a faint trace of albumin

The patient returned to the clinic in July 1946 presenting a number of discrete, somewhat lichenified patches around both ankles Under treatment with bland ointments the condition improved over a period of two months

In March 1947 the patient again visited the clinic At this time he had an eruption on the ankles, elbows, knees and dorsa of the fingers (terminal phalanges) On the ankles there were areas made up of violaceous shiny papules, on the elbows and knees there were many small flesh-colored papules, some in linear arrangement along scratch marks (Koebner phenomenon) There were no lesions on the trunk or genitals A diagnosis of lichen planus and possible lichen nitidus was made

A specimen taken from a lesion of the right elbow showed the epidermis to be covered by a thin keratin layer The basal cells were heavily pigmented At one point, just beneath the epidermis, there was a localized collection of inflammatory cells, including mononuclear cells and polymorphonuclear leukocytes The epidermis overlying this nodule of inflammatory cells appeared somewhat compressed and thinned out The histologic picture was consistent with a diagnosis of lichen nitidus A roentgenogram of the chest showed no abnormalities Results of quantitative tuberculin (human and bovine) tests in dilution of 1 10,000 and 1 100,000 were negative Kahn and Kline reactions of the blood were negative The urine was normal

DISCUSSION

DR MAX JESSNER The question of the occurrence of lichen planus and lichen nitidus simultaneously is an old one The patient shows definite lichen planus on the ankles, the lesions on the arms resemble lichen nitidus At the outset the lesions look almost alike There have been cases reported in which the two types have been found together One should, however, have histologic evidence in order to corroborate both diagnoses I think that the picture in this case fits in with the lichen planus type, especially in view of the lesions on the ankle

DR PAUL GROSS The case is of interest because of the rare association of lichen planus and lichen nitidus The tissue was somewhat damaged in the preparation for histologic examination, and, therefore, a definite diagnosis of lichen nitidus could not be made The typical tubercle-like structure was lacking, but it may be that even in lichen nitidus a nonspecific granuloma is present in the early stage of the lesion

DR WILBERT SACHS Conclusions cannot be drawn from this slide I agree with the diagnoses of lichen planus and lichen nitidus I have seen 2 similar cases

DR JOSEPH L MORSE As Dr Gross pointed out, this case was presented because of the rare association of the two diseases The lesions around the ankles were certainly characteristic of lichen planus An effort will be made to obtain biopsy specimens from both types of lesions

DISCUSSION

DR CHARLES WOLF I could not see any clinical manifestations of Majocchi's disease There is, however, a vasocirculatory disturbance present which produced sclerosis of the peripheral vessels I think that the pulsation in the dorsalis pedis is, if not entirely obliterated, at least decreased The atrophic changes are due to the sclerosis of the peripheral blood vessels

DR DAVID BLOOM Clinically the eruption resembles radiodermatitis No other diagnosis can be made from the appearance of the lesions tonight

DR MAX JESSNER I would be more inclined to regard this case as one of radiodermatitis, especially in view of the fact that ten roentgen ray treatments had been given to the area Moreover, the lesions suggest healed ulcers, perhaps with superimposed radiodermatitis The patient also presents a peculiar thickening of the skin of both knees, with yellowish discoloration, not unlike housewife's knee, which I do not remember ever having seen previously However, the usual keratosis in housewive's knee is missing here

DR LOUIS CHARGIN I agree with those who are of the opinion that this is not Majocchi's disease In Majocchi's disease the lesions are much smaller, situated higher up on the legs, usually there is some atrophy in the center, and the lesions are annular I cannot classify this process, but these scleroderma-like changes are not infrequently seen in elderly persons, particularly women

DR ERNST NATHAN The patient presents atrophic patches on the knees and on the legs, linear stripes along the tibias and scleroderma-like changes, all of which impressed me as acrodermatitis chronica atrophicans with scleroderma-like changes

DR WILBERT SACHS I do not consider radiodermatitis or scleroderma in this case Clinically, Majocchi's disease must be distinguished from Schamberg's disease and similar processes However, since Majocchi's presents a definite histologic picture, a biopsy would settle the diagnosis

DR PAUL GROSS As Dr Wolf stated, the cutaneous condition of this patient can be explained only by a vascular disturbance which leads to sclerosis of the peripheral blood vessels and atrophy of the skin The pathologic process accounts for the clinical manifestations consisting of telangiectasis, purpura, necrosis and atrophy This could be clearly followed by prolonged observation of the patient while she was in the hospital

The unusual feature of this case was the extensive ulceration which developed on the dorsa of the feet Because of this, it was difficult to consider the diagnosis of Majocchi's purpura unless there was something in the pathologic changes of the disease which could explain the atypical manifestations Actually necrosis has been described as part of the histologic picture of purpura annularis Apparently the severity of the vascular damage in this case produced sufficient necrosis to lead to ulceration Secondary infection may have been an added feature and has aggravated the formation of ulcers The improvement of the circulation by treatment with bed rest and antiseptic ointment brought about healing of the ulcers in a relatively short time If the ulcerations had been the result of a chronic radiodermatitis, the patient would have experienced severe pain, and healing would not have been prompt Prior to the patient's admission to the hospital, the case had been managed as a case of radiodermatitis without benefit

Dermatitis Herpetiformis Arsenical Keratoses and Pigmentation. Ulcer of the Leg Presented by DR ALEXANDER A FISHER

Tinea Glabrosa, Dermatophytosis, Onychomycosis, Pityriasis Versicolor, Erythrasma and Tinea Versicolor Appearing in the Same Patient Presented by DR EMANUEL MUSKATBLIT and (by invitation) DR L TULIPAN

The patient, a white man aged 65, has been seen at the Clinic of the New York University presenting several types of fungous infection 1 On both cheeks, especially the left one, in front of the ears, there is a faint erythema and scaling of about three weeks' duration Scrapings showed fungi of the ringworm type 2 On the neck there is a faint erythema, scaling and hyperpigmentation of a few weeks' duration 3 The upper middle part of the chest shows erythema, scaling, hyperpigmentation and some lichenification of about two months' duration Scrapings from the left side of the neck and chest showed fungi of the ringworm type 4 On the back there is a brownish scaly patch with numerous brownish macules on the periphery The duration is unknown Examination of the scales showed Malassezia furfur 5 On the left thigh there is a brownish-reddish patch with slight scaling and small foci on the periphery, of ten years' duration Scales from the thigh showed Actinomyces minutissimus and M furfur 6 The soles and lateral aspects of the feet showed scaling The toes and webs showed scaling and maceration of ten years' duration The toe nails showed yellowish and grayish patches and dulness Scrapings from the feet, toes and right big toe nail showed fungi of the ringworm type Cultures were planted with material obtained from areas infected with ringworm

NOTE—The toes showed Trichophyton purpureum All other culture tubes failed to show pathogenic fungi

Henry Silver, M D, *Secretary*

Oct 23, 1947

Mycosis Fungoides, Fungoid Stage, Treated with Antimony Preparations Presented by DR JOHN GARB

D N, a woman aged 49, was registered at the Skin and Cancer Unit of the New York Post-Graduate Medical School and Hospital on Jan 17, 1940, presenting lesions of two years' duration The eruption began on the left thigh with a red, nonitchy, oblong patch about 3 inches (8 cm) in diameter Several months later oozing vesicular and crusted patches appeared on the chest and, shortly after, on the neck On the trunk the patches were erythematous and covered with silvery scales and showed minute bleeding points At that time a diagnosis of psoriasis vulgaris was made

On Jan 7, 1942, the microscopic examination of a specimen taken from the left elbow showed chronic eczema

Senile Elastosis of the Neck (Pseudo Xanthoma Elasticum?) Presented by DR PAUL GROSS

A Case for Diagnosis (Necrobiosis Lipoidica? Tuberculoderm?) Presented by DR MORRIS LEIDER and (by invitation) CAPT CHARLES D BELL

Ragweed Dermatitis Presented by DR ALEXANDER A FISHER

P B, a man aged 64, was in good health and free from any cutaneous disease until September 1936, when he walked barefoot through some lots in Astoria, N Y A vesicular eruption appeared on the back of the feet and legs It was diagnosed as dermatitis due to poison ivy and persisted for five months

The eruption recurred in September 1937, affecting mildly the feet, legs, face, hands, forearms and scrotum It then became perennial, with exacerbations from September to May The most comfortable months were June and July

At present there are thickened lichenified lesions on the face and forearms On the face the eruption is sharply limited to the upper part of the forehead

Patch tests with the following oleoresins gave positive reactions short ragweed, cocklebur, sheep sorrel, Kentucky blue grass, red top, short poison ivy, orchard grass and timothy Patch tests with protein extracts of trees, grasses and weeds showed a positive reaction only to oak Results of scratch tests with these protein extracts were negative The result of a patch test with a 5 per cent glycerine solution of ragweed oil (Hollister-Steer) was negative The patient has received oral treatment with oleoresins according to the Shelmire method

DISCUSSION

DR RUDOLF L BAER The patient had a positive reaction to the so-called "protein" fraction of the oak pollen I do not know whether there is any evidence that the oak protein has been of clinical significance Among the extracts available for testing, the "protein" fraction of oak pollen was included Unfortunately, no acetone extract of oak was available, so that it is impossible to state whether this patient is also sensitive to the oil fraction

It is probable that the fractions contained in various extracts differ considerably A patient suffering from a similar eruption at the New York Skin and Cancer Unit was tested with the following ragweed extracts (*a*) the oleoresin, (*b*) the so-called "protein" fraction in a glycerinated extract and (*c*) the so-called "protein" fraction in a powdered extract This patient reacted to the oleoresin fraction and to the powdered "protein" extract but not to the glycerinated extract, which is supposed to contain the same fraction as the powdered extract This indicates that there is a great difference between preparations which, it is assumed, contain the same fraction

DR CHARLES WOLF The history indicates that this patient was exposed to various flowers and pollens a long time ago, but not recently Still he exhibits a fairly pronounced eruption on the face and forearms, although he has not been in contact with these suspected allergens How can one explain the fact that the dermatitis still persists? Is it possible that this patient's sensitivity is polyvalent and reacts to many agents? What is the therapeutic approach to this problem?

The patient was readmitted to the New York Post-Graduate Hospital on Jan 8, 1943 At that time she presented a generalized erythematosquamous eruption The lesions were sharply marginated, of various sizes and round or oval, and they formed bizarre patches by confluence Most of them were elevated above the level of the surrounding integument and were edematous and infiltrated

In February 1943 a section of a specimen taken from the left forearm was examined histologically by Dr C F Sims The epidermis showed moderate and somewhat irregular acanthosis, with areas of parakeratosis alternating with retained granular layer Moderate intercellular edema and cellular infiltration were visible In the upper part of the corium were numerous small dilated vessels with edematous and thickened walls surrounded by moderate cellular infiltration of a polymorphous character Small round connective tissue cells, epithelioid cells, histiocytes and plasma cells were present In the zone of infiltration there was moderate interstitial and parenchymatous edema The histologic diagnosis was mycosis fungoides

The hemogram was normal, and the eosinophil count, 5 per cent The Wassermann reaction of the blood was negative The sedimentation rate was 10 mm per hour (normal in women, 19 mm per hour), as determined by the Westergren method Tests with old tuberculin elicited negative reactions in dilutions down to 1 5,000 and a plus-minus reaction in a dilution of 1 1,000 The icteric index was normal Roentgenograms of the chest revealed isolated old, calcified, central and parenchymal tubercle scars

During the seven years of observation the therapeutic measures included adequate courses of superficial fractional roentgen radiation exposures, courses of ultraviolet irradiation, and the administration of testosterone, oxophenarsine hydrochloride (mapharsen®) calciferol (vitamin D_2), promin® (sodium p,p'-diaminodiphenylsulfone-N,N'-didextrose sulfonate) intravenously and locally, bismuth subsalicylate, ethyl chaulmoograte, diphtheria toxoid, sodium arsenate, resin of podophyllum, riboflavin, ascorbic acid and anterior pituitary extract

During these years the patient showed no spontaneous remission of any of the lesions There was some temporary regression due to the roentgen irradiation or to some of the other therapeutic agents There was a tendency for most of the lesions to recur in a more aggravated form, and new lesions continued to develop

On April 28, 1947, treatment with antimony potassium tartrate was instituted On May 19, 1947, after ten intravenous injections of 5 cc of a 1 per cent solution of antimony potassium tartrate, given three times weekly, there was spectacular improvement The superficial patches were rapidly undergoing involution, and the raised growths were flattening out

From June 4 to August 8, because of possible toxic reactions, the treatment was changed to triweekly intramuscular injections of stibanose® (the diethylamino ethanol salt of sodium antimony gluconate), 4 cc per dose, the compound being a pentavalent antimony preparation containing 20 mg of antimony per cubic centimeter A total of nineteen injections was given On August 6, the patient was about 80 per cent improved

Electrocardiograms were taken every two to four weeks On August 11 minimal myocardial changes were observed Treatment with stibanose® was discontinued and crude liver extract and thiamine hydrochloride were given

On October 4 the electrocardiogram did not reveal any abnormalities of the ventricular complexes Injections of stibanose® were resumed twice weekly, alternating with administration of liver and thiamine hydrochloride

DR MARION B SULZBERGER In the preparation of plant extracts with the usual variety of solvents, one extracts a great number of different substances in each of the fractions Dr Coca and I have demonstrated that in the case of allergic contact dermatitis to ragweed and to certain other plants it was a fat-solvent soluble fraction which contained the usual allergen This might be misinterpreted The fact is that in most common forms of allergic eczematous contact dermatitis, water-soluble materials, including many dyes, metallic salts and local anesthetics, are responsible

DR ALEXANDER A FISHER This case is puzzling Some are of the opinion that the oil remains in wearing apparel for many months There is also, as Dr Wolf suggests, a possibility that this patient became allergic to pyrethrum, which is related chemically, and that is what causes the eruption to become perennial As Dr Sulzberger pointed out, the aqueous fraction is frequently responsible for the dermatitis The Mitchells have reported a case of the disease due to aqueous fraction of timothy which they were able to cure by injections of the ordinary extract used for hay fever

Angioma Resembling Idiopathic Multiple Hemorrhagic Sarcoma Presented by DR HARRY B FEILER

Wilbert Sachs, M D, *President*
Henry Silver, M D, *Secretary*
March 20, 1947

Erythroplasia (Cured by Application of a Mixture of Neoarsphenamine, Glycerin and Water) Presented by DR WILBERT SACHS and DR PERRY M SACHS

Erythroplasia of Queyrat (No Biopsy) Presented by DR CHARLES PINES

Poikiloderma Vasculare Atrophicans (Jacobi) Presented by DR FRANCES PASCHER

Pityriasis Rubra Pilaris Presented by DR DAVID BLOOM

F C, a woman aged 57, registered at the Skin and Cancer Unit of the New York Post-Graduate Hospital on Feb 14, 1947, complaining of an eruption of five weeks' duration The past and family histories were irrelevant

The patient presents on the face erythematous scaly plaques which toward the neck are associated with spinulous follicular keratotic plugs On the anterior and posterior aspects of the trunk there are irregularly shaped, erythematous scaly patches and groups of keratotic follicular yellowish or skin-colored papules or plugs the size of a pinpoint or pinhead On the extensor surfaces of the forearms and hands, lateral aspects of the arms and thighs, there is a similar eruption The scalp shows diffuse scaling On the forehead and around the eyes there are numerous small fibromatous lesions and skin tags The palms and soles show considerable brownish-yellowish hyperkeratosis

The patient has no subjective complaints and seems to be otherwise in good health

Examination on October 17 showed that all lesions, except for an isolated few, had completely regressed, leaving faintly superficial, reddish to purplish spots and dark brown patches The breasts, except for two small superficial patches, were entirely clear, the foul-smelling, crusted patches were replaced by normal epidermis A nodular growth on the middle of the left leg remained unchanged

DISCUSSION

DR FRANK E CROSS I should like to ask Dr Garb for the rationale of the use of antimony salts in the treatment of mycosis fungoides

DR JOHN GARB During the past five years I have experimented with many forms of treatment in mycosis fungoides, including promin,® testosterone propionate, diphtheria toxoid, chaulmoogra oil and many others The effect of these measures was only partial and temporary The use of antimony salts was purely experimental, prompted by the success obtained with them in treatment of granuloma inguinale The rapid melting of the ulcerated growth in mycosis fungoides (50 per cent improvement within three weeks) exceeded my expectation

DR CHARLES F SIMS I have examined several sections of specimens obtained in this case One of them presented a pleomorphic cellular infiltration in the upper part of the corium, as well as other histologic changes consistent with the diagnosis of mycosis fungoides

DR SAMUEL M PECK If this is truly a case of mycosis fungoides—and I value Dr Sims' opinion—then the treatment with antimony salts would rank as one of the important contributions to modern therapy It is well known that mycosis fungoides is a type of lymphoblastoma I hesitate to admit that the lymphoblastomatous type of lesion would respond to such a therapeutic measure If the antimony salts really have a beneficial effect on mycosis fungoides, it would be necessary for this disease to be removed from the group of lymphoblastomas I do not believe, however, that antimony salts would have such a beneficial effect on malignant lesions I have treated a variety of dermatoses, principally psoriasis, with antimony salts and have seen such cases clear up after one treatment However, recurrent lesions are resistant to antimony Further trial with antimony salts in treatment of mycosis fungoides is certainly indicated

DR BORRIS A KORNBLITH (by invitation) I have had much experience with antimony compounds, especially in the treatment of granuloma inguinale I have employed antimony potassium tartrate, stibophen (fuadin®), antimony sodium thioglycollate and stibanose® Since granuloma inguinale is a chronic disease and requires a prolonged period of therapy, a number of pertinent observations were possible in evaluating these antimony preparations

It is possible for one to give any of the antimony preparations up to a point of toxicity and to continue with a subtoxic dose for long periods because of the rapid excretion of these compounds through the kidney (for the most part, 80 per cent in twenty-four to forty-eight hours) and through the bowel (10 per cent) For cases requiring larger dosage for maximum therapeutic effect, stibanose® is by far the most advantageous drug There is no pain associated with its subcutaneous or intramuscular administration, while the other antimony preparations, such as antimony potassium tartrate, stibophen and antimony sodium thioglycollate, produce pain when given intramuscularly In general, it may be stated that larger doses of antimony are not possible because of the toxicity of the drug When a less toxic drug is introduced, the larger doses are well tolerated and a better

Results of laboratory examinations, including urinalysis, a Wassermann test of the blood and a determination of the vitamin A content of the blood, were normal The blood cell and differential count showed an abnormal low white cell count of 3,500 and relative lymphocytosis (56 per cent lymphocytes) The report of the histologic examination of an erythematous lesion taken from the abdomen was possible early exudative lichenoid discoid dermatosis

DISCUSSION

DR WILBERT SACHS Microscopically there is no evidence of this disease The picture is that of exudative discoid and lichenoid dermatosis Recently Dr Perry Sachs and I reported 3 cases occurring in female patients (*J Invest Dermat 8 215, 1947*)

DR PAUL GROSS I agree with Dr Bloom that this is a case of pityriasis rubra pilaris The patient has leukopenia, it would also be of interest to make a complete hemogram I recommend treatment with crude liver extract and folic acid

DR DAVID BLOOM I presented this case because it is clinically typical, and yet the results of the histologic examination did not confirm the diagnosis It should be noted that when the biopsy specimen is taken from an erythematous plaque in which the keratotic papules have disappeared the pathologist is unable to make a diagnosis of pityriasis rubra pilaris I wish also to mention that a majority of the patients with pityriasis rubra pilaris that I have observed were all in the fifth decade and not young persons as mentioned in dermatologic textbooks

DR PAUL GROSS O'Leary makes a distinction between pityriasis rubra pilaris and pityriasis-rubra-like eruptions I think that this division is justified by the clinical picture, course and response to therapy I cannot agree with Dr Bloom concerning the age groups involved I have seen several children with extensive eruptions, usually with a sudden onset, showing the clinical features of pityriasis rubra pilaris These patients have shown a dramatic response to a combination of vitamin B complex and vitamin A

Early Mycosis Fungoides, Psoriasiform Lesions Presented by DR ADOLPH ROSTENBERG and DR WILLIAM M SISKIND

Idiopathic Onycholysis, Improved with Thyroid and Vitamin A Therapy Presented by DR ALEXANDER A FISHER

V C, aged 16, first noticed about three years previously that the nails became soft and separated from the nail bed

When first seen, on Dec 17, 1945, all finger nails were involved (kodachrome® slide presentation) He had been under the care of another dermatologist for one and one-half years and had received roentgen ray treatment, ultraviolet rays and various ointments without apparent effect

Results of the physical examination were normal except for a pulse rate of 82 A medical consultant stated that at this age basal metabolism readings are not reliable, and the basal metabolic rate was therefore not established The patient was given thyroid, ¼ grain (16 mg) three times a day

When he returned in a week the pulse rate was 92, and he complained of nervousness The dose of thyroid was then reduced to ¼ grain twice daily, and he was given, in addition, vitamin A, 100,000 units daily, to augment the

therapeutic result obtained Initial resistance to antimony, however, is not overcome by increasing the dose

The immediate toxic reactions, in the order of their appearance, are as follows hacking cough, circumoral pallor, blanching of the face, respiration, nausea, retching, vomiting and vasomotor collapse All these symptoms are ameliorated by the prompt use of epinephrine subcutaneously (8 to 10 mm of a 1 1,000 solution) The late symptoms of toxicity are myalgia, especially of the deltoid and the quadriceps femoris muscles, pain along the distribution of the trigeminal nerve, especially in decayed teeth, and cardiac irregularities, such as bradycardia and auricular fibrillation, with occasional electrocardiographic changes

All observations were made on ambulatory patients, who tolerated the antimony drugs in a surprisingly asymptomatic way despite the large doses used

DR JOHN GARB I am in accord with Dr Peck If treatment with antimony preparations should prove effective in other cases of mycosis fungoides, then mycosis fungoides should be taken out of the group of lymphoblastomas

Similar remedies, such as chaulmoogra oil, are sometimes used in the treatment of leprosy and of mycosis fungoides It is interesting to note that antimony salts, alone or in combination with arsenic, have been used in the treatment of leprosy, with varying degrees of success, by Kingsbury and others (A New Antimony Compound in the Treatment of Leprosy, ARCH DERMAT & SYPH **24** 1053 [Dec] 1931)

As Dr Kornblith pointed out, the pentavalent antimony preparation stibanose® is the least toxic of all antimony products Nevertheless, toxic reaction, especially myocardial damage, must be guarded against

Keratosis Follicularis (Darier's Disease) Presented by DR NATHAN SOBEL

D N, a girl aged 14, presents an eruption which has been present for seven years, but which has become aggravated in the past four years The patient has no brothers or sisters The mother, father and other relatives are not affected by the disease

In both supraclavicular regions and on the sides of the neck there are areas of erythema the size of a palm, with extensive oozing and yellowish crusting The scalp and upper part of the forehead show similar areas There are numerous discrete keratotic lesions the size of a pinhead in the perioral region and also on the neck

Histologic examination on May 3, 1947, showed pronounced hyperkeratosis and an increased granular layer in some areas Classic corps ronds and grains were present in some sections There were lacunas just above the basal cell layer and also within the prickle cell layer in many areas The histologic diagnosis was keratosis follicularis (Darier's disease)

At the clinic the patient received injections of liver extract, potassium arsenite solution (Fowler's solution) and vitamin A by mouth During the summer of 1947 she also had ten intramuscular injections of a preparation containing 100,000 units of vitamin A, given triweekly, with little benefit Since Sept 4, 1947, she has been treated at my office Treatment has consisted of administration of a compound containing 200,000 units of vitamin A daily by mouth in combination with ox bile extract (bile salts) Six roentgen ray treatments were given to the supraclavicular regions and neck There has been moderate improvement However, the patient states that the condition is at its worst in the summer

thyroid therapy For four months there was no change in the nails By June 1946 there was definite improvement, which has been continuous At present all the nails have practically returned to normal

DISCUSSION

DR PAUL GROSS There is a definite relationship between the thyroid and the vitamin A metabolism In cases of hypothyroidism there is frequently a vitamin A deficiency The excellent therapeutic result obtained by Dr Fisher is noteworthy

DR EMANUEL MUSKATBLIT It seems to me that onycholysis is not always of the same origin Some of these cases have an occupational background In others a separation of the nail from its bed results when the patients constantly soak their hands in water In such cases removal of the cause results in a cure

DR HENRY SILVER I consider the point raised by Dr Muskatblit pertinent The role of continuous use of soap and water should not be underestimated, particularly in patients with systemic disturbances The condition in this case, with the manifest thyroid disturbance, may well fall in this group (Silver, H, and Chiego, B Brittleness of Nails, *J Invest Dermat* **3** 5, 1940)

DR ALEXANDER A FISHER In spite of this boy's washing his hands many times a day, he is improving with vitamin A and thyroid therapy Moreover, it is strong alkali which causes onycholysis, and he denies the use of strong soaps

Circumscribed Scleroderma (Treated with Promin®). Presented by DR HARRY B FEILER.

L S, a woman aged 74, has been complaining of pain, burning sensation and tightness of the skin of the chest In May 1946, she noticed a patch about 3 by 1½ inches (8 by 4 cm) in diameter, located on the right side of the chest, which was hard, white and glistening and was surrounded by a violaceous border At present the lesion is still of the same size The blanched area is somewhat softer and has the remnant of the violaceous border Recently a few linear lesions appeared above the involved area

The patient has been given polyvitamins by mouth, and, with this regimen, there was a disappearance of the leathery consistency in the lesion, but otherwise there was no change She has received intramuscular injections of 50,000 units of vitamin A every second day for three weeks without any noticeable improvement

For the past week promin® (sodium p,p'-diaminodiphenylsulfone-N,N'-didextrose sulfonate) jelly has been applied There developed dermatitis at the site of the lesion accompanied with pain and burning sensation Treatment with promin® was discontinued

DISCUSSION

DR DAVID BLOOM Morphea may disappear without treatment Unless the effect is rapid, one cannot prove that promin® is therapeutically useful in morphea

DR ALEXANDER FISHER If no improvement takes place with promin® I would suggest bismuth subsalicylate Dr John A Stokes first mentioned this type of therapy Several patients at the Skin and Cancer Clinic have improved with treatment with bismuth preparations

DR. CHARLES R REIN Dr Carol Wright and Dr Elmer Gross have had excellent results in the treatment of scleroderma with a bismuth preparation (bistrimate®) given orally

DISCUSSION

DR NATHAN SOBEL A diagnosis of familial benign chronic pemphigus (Hailey and Hailey) was considered in this case, but the diagnosis of keratosis follicularis was established on the basis of histologic findings The patient is presented because of the failure of the condition to respond to large doses of vitamin A and liver

DR SAMUEL M PECK There are two curious facts that stand out in the treatment of keratosis follicularis with large doses of vitamin A (1) there is a peculiar relation between keratosis follicularis and exposure to light, and (2) some patients who do not respond to oral therapy respond to injections

Exposure to sunlight causes aggravation of the eruption and, at times, vesiculation My patients learn soon enough not to go to the beach It is my experience that lesions on the exposed parts, such as the forehead, face and neck, are more resistant and clear much later than those in comparatively protected areas, such as the axillas It is evident that the light factor plays an important role

Some cases which do not respond to vitamin A therapy alone do respond to treatment with a combination of vitamin A and members of the vitamin B complex This fact was called to my attention by Dr Gross Vitamin B metabolism apparently plays a role in the second factor If some patients do not respond to treatment with vitamin A, it should be supplemented by injections of liver and large doses of nicotinic acid

DR CHARLES R REIN In other cutaneous conditions associated with vitamin A deficiency, the administration of large doses of vitamin A orally did not produce a beneficial effect until absorption from the gastrointestinal tract was implemented by the concomitant ingestion of dilute hydrochloric acid Such a regimen might be effective in treatment of this patient

DR HANS STORCH, Zurich, Switzerland (by invitation) A case of keratosis follicularis recently under observation at the University Clinic in Zurich has responded remarkably well to treatment with grenz rays

DR NATHAN SOBEL With respect to Dr Peck's remarks regarding exposure to light and keratosis follicularis, I can state that this patient's condition had been aggravated during the summer Since it is believed that sunlight has a bad effect on this condition, another patient under my observation was kept out of the sun's rays but failed to improve I also exposed a small area of the back of that patient to ultraviolet rays in erythema doses, but no new papules have formed I believe there must be some factor other than sunlight to aggravate the condition during the summer months The patient I presented tonight also failed to improve by avoidance of sunlight She has already been given injections of crude liver extract I shall, however, follow the suggestions of Drs Peck and Rein and try treatment with nicotinic acid and hydrochloric acid I may also try the use of grenz rays, as suggested by Dr Storch

Livedo Reticularis, with Recurrent Superficial Ulcerations of the Feet Presented by DR SAMUEL M PECK and DR KAI K LI (by invitation)

Purpura Annularis Telangiectodes (?). Presented by DRS PAUL GROSS and ELLEN REINER

Wilbert Sachs, M D, *President*
Henry Silver, M D, *Secretary*
April 17, 1947

Superficial Epitheliomas, Treated with Podophyllin Presented by DR JOHN GARB

M B, a man aged 73, was first seen on July 17, 1946, presenting three cutaneous lesions He had pneumonia in 1916 He has otherwise been in good health

The largest of the three lesions is located on the left lower border of the anterior part of the chest and epigastrium It is roughly round, 3 inches in diameter (7 5 cm) and dry, with a slightly raised border In that circle are several raised, crusted, irregular, dark red to purplish lesions, which are rough to the touch Most of the lesions have cleared with topical remedies and with exposures to ultraviolet rays, leaving a slightly darker but normal-appearing skin This lesion has been present for the past four years On the inner third of the right clavicle there is a similar patch 1 cm in diameter and an oval patch with axes of 7 and 5 cm on the left side of the back There is a scar in the midportion of the back as a result of an operation performed in 1945 for a carbuncle

The routine laboratory tests showed no abnormalities

Sections were taken from specimens of lesions on the front and back of the chest and examined histologically by Dr Charles F Sims The former showed a somewhat irregular epidermis At one point, extending down into the corium on the under surface of the basal margin, was a small mass composed of basal cells The vessels of the upper part of the corium were moderately dilated and surrounded by mild interstitial edema and a nonspecific cellular reaction From the histologic examination the diagnosis was superficial basal cell epithelioma

Microscopic examination of the specimen taken from the lesion of the back showed features of superficial dermatitis

An ointment containing 5 per cent podophyllin prepared with 8 Gm of castor oil and aquaphor® (an oxycholesterol-petrolatum ointment base), enough to make 2 ounces (57 Gm), was applied on January 30 to the lesions of the chest On February 1, the lesions became ulcerated and a soothing ointment was applied On February 18, the rim of the lesion on the frontal part of the chest was still visible but not raised On February 25, the upper part of the patch on the back was still elevated On March 4, an ointment containing 10 per cent, and on March 11 and 13, 20 per cent of podophyllin was applied to a few spots on the frontal part of the chest On March 31, the 10 per cent ointment was applied to a few spots on both lesions On April 10, the lesion on the back appeared healed except for slight roughness The lesion on the front part of the chest was flattened to the level of the surrounding skin surface The border was still visible because of the brownish pigmentation A section was taken from the pigmented border close to the scar of the original section which showed basal cell epithelioma The histologic examination by Dr A M Sala showed atrophy of the epidermis and moderate round cell infiltration of the corium which appeared somewhat edematous There was no histologic evidence of neoplastic tissue

DISCUSSION

DR MARION B SULZBERGER The lesions give the impression of a superficial epithelioma either entirely healed or in the process of healing Whether a recurrence will take place one cannot foretell Several points need be considered

A Case for Diagnosis (Epidermodysplasia Verruciformis?) Presented by DRS MAX JESSNER and CHARLES R REIN

E W, a man aged 21, presents an eruption of five years' duration It began as a few discrete lesions on the forehead and reached the present stage within a few months The patient has received various types of therapy, including peeling, administration of wart vaccine and roentgen irradiation, with no appreciable change

His parents are nonrelated He states that his older sister has wartlike lesions on the fingers which have persisted for the past several years

The eruption is most conspicuous on the face and consists of discrete, light brown, nonscaly papules varying in size from that of a pinhead to that of a pea Many of these lesions are made up of groups of smaller lesions, some of them taking on an annular configuration The lesions over the bearded portion of the chin are quite characteristic of verruca plana There is a solitary verrucous lesion, the size of a large pea, on the dorsum of the left hand Several of the lesions were destroyed by electrodesiccation and curettage, which resulted in keloidal scarring A lesion of the forehead was removed for microscopic examination Dr C F Sims reported that the epidermis was moderately verrucous There was some elongation and broadening of the rete pegs at many points Considerable vacuolation of the cells of the granular layer and the upper rete cells was observed No noteworthy changes were present in the corium

DISCUSSION

DR EMANUEL MUSKATBLIT The lesions impress me as ordinary verrucae planae What clinical features justify the other diagnosis?

DR HENRY SILVER I hesitate to make a diagnosis of epidermodysplasia verruciformis in this case, but I should definitely rule out verruca plana I admit that the histologic evidence, such as ballooning of the cells and the basket weave appearance of the epidermis, is characteristic These features, however, are not limited to epidermodysplasia verruciformis but are seen in other diseases, such as verruca senilis, mal de Meleda and molluscum contagiosum, and even in common warts We cannot, therefore, rely solely on the histologic evidence Because of our lack of knowledge regarding etiology of the disease, it is difficult and often confusing to separate the clinical varieties encountered These variants of localized or region-specific keratoses are often considered as separate entities on flimsy evidence It is highly probable that epidermodysplasia verruciformis of Lewandowsky and Lutz, Hoffman's verrucosis generalisata and possibly Hopf's acrokeratosis verruciformis are clinical variants of the same disease

The well developed cases of epidermodysplasia verruciformis are readily diagnosed Most of the characteristic features, such as the disseminated, verruca-plana-like lesions, the tendency to malignant transformation, the verruca-vulgaris-like lesions and the verrucous plaque formations, are usually present The case I presented before the Section of Dermatology of the New York Academy of Medicine was a fairly characteristic example of the disease (Epidermodysplasia Verruciformis, ARCH DERMAT & SYPH **45** 836 [Nov] 1941) Dr Rein's case lacks some of the clinical features I would therefore consider his case a forme fruste of the disease

DR PAUL GROSS In spite of the fact that the diagnosis epidermodysplasia verruciformis is still in doubt, I should definitely rule out the suggested diagnosis of verruca plana on clinical grounds

Certain superficial epitheliomas respond quickly to many forms of therapy Mild caustics and other superficial destructive measures may cure most superficial and small basal cell epitheliomas In evaluating any new therapy, one should keep in mind the ease with which nonspecific measures can remove these so-called carcinomas

Podophyllin is a peculiar substance which has some influence on mitosis As Maurice Sullivan, Lester S King and others have pointed out (in Wise, F, and Sulzberger, M B Yearbook of Dermatology and Syphilology, Chicago, The Year Book Publishers, Inc, 1946, p 510), podophyllin, like colchicine, somehow affects the nuclear metabolism and one sees many cases of arrested mitosis, all in the same phase—the metaphase, I believe It is, therefore, possible that podophyllin or podophyllotoxin may have some specific effect on the multiplying cells of the carcinoma and that the results achieved may be more than a mere nonspecific destructive action The action of podophyllin is well worth studying in relation to epithelial growth and deserves a good deal of further careful experimentation

DR FRANK E CROSS New methods of therapy that are simple and promising should be encouraged, on condition that they are as good as or better than the older ones Dr Sulzberger just stated that podophyllin seems to have a basic action in that it interferes with mitosis On the other hand, I take exception to his statement of the "simplicity of ordinary epitheliomas" It is true that a treatment of some basal cell epitheliomas is simple, in others, however, radical measures must be resorted to

DR WILBERT SACHS A biopsy specimen taken from the "healed" area will determine whether any carcinomatous tissue still remains

DR JOHN GARB The patient had the lesion on the left lower border of the chest and the epigastrium for forty years A biopsy specimen taken from the pigmented margin adjacent to the original histologic section did not show any epitheliomatous change The patient was not presented tonight as cured He will be kept under observation

Dermatitis Due to Gold, Successfully Treated with BAL (2,3-Dimercaptopropanol) on Two Occasions Presented by DR MARION B SULZBERGER

DISCUSSION

DR ADOLPH ROSTENBERG I used BAL in a case of a widespread dermatitis of unknown cause, and the result was excellent It required several weeks of treatment, but after one injection there developed a severe nitritoid reaction, such as is observed after administration of arsphenamine preparations I have never observed it since and wonder whether this reaction occurs commonly

DR DAVID BLOOM Before administration of BAL the cardiovascular status of the patient should be determined A few weeks ago I observed a patient who received BAL for suspected intoxication due to bismuth This patient, who received an excessive dose of BAL, had a severe reaction manifested by a sensation of burning and constriction about the mouth, face and chest The patient appeared rather ill It was later discovered that this patient had myocardial damage

DR MARION B SULZBERGER This patient was presented to demonstrate therapeutically the effectiveness of BAL in dermatitis due to gold One interesting feature in this case is that the BAL therapy has been effective twice The eruption got worse when BAL therapy was discontinued and then rapidly improved with readministration The therapy was stopped for the reasons given by Dr

DR DAVID BLOOM From the appearance of the lesions, it is difficult for one to make a diagnosis of epidermodysplasia verruciformis, but one has to favor this diagnosis because of the plaque formation on the face The vacuolation of the epidermal cells seems on histologic examination to support the diagnosis as presented, although such changes are reported also in verruca plana and in other keratotic and dyskeratotic conditions I should like to call attention to the type described in the French literature as *erythrokératodermie verruqueuse en nappes*

DR. CHARLES LERNER In my opinion this is a case of verruca plana, if I may judge from the lesions that I observed on the dorsum of the left hand

DR MAX JESSNER I have little to add to Dr Silver's remarks Dr Rein and I expected a difference of opinion about this case, and for this reason we presented the patient The question of whether epidermodysplasia verruciformis is a dermatosis *sui generis* has become acute again since W Lutz's article appeared in *Dermatologica* in 1946 Epidermodysplasia verruciformis had already once to fight for its existence and nevoid nature when it was confronted with verruca disseminata and verrucosis generalisata, respectively At that time it had, we believed, won the fight Such cases as Lewandowsky and Lutz's first one, which I saw, are impressive, and their nevoid and rather often precancerous nature ought not to be doubted A case not as widespread, with several epitheliomas, shown to me by Dr de Cholnoky, will be presented at a subsequent meeting It is the more or less abortive forms resembling clinically verruca plana which are difficult to diagnose, especially if the vacuolation of the rete cells is not outstanding and because of the fact that a certain degree of vacuolation may also be found in warts In the case presented it is the clinical aspect, especially the confluence of the lesions in some parts of the affected region, and the course of the disease, together with the histologic features, that favor a diagnosis of epidermodysplasia verruciformis

DR CHARLES R REIN I have learned that the patient's sister also had verrucous lesions on the hands If this point is confirmed, it will corroborate the diagnosis as presented The differential histologic diagnosis lies between verruca plana and epidermodysplasia verruciformis The clinical findings, history and course of the condition must be taken into consideration before a definite diagnosis can be established

Parapsoriasis Varioliformis Presented by DR FRANCES PASCHER

Juxta-Articular Nodes in a Patient with Neurosyphilis Presented by DR JULIUS H POLLOCK

Basal Cell Epithelioma of the Nipple of a Man Presented by DR NATHAN SOBEL

L S, a man aged 46, has been a patient at the Skin and Cancer Unit of the New York Post-Graduate Hospital since Sept 19, 1947 The duration of the lesion is not definitely known, but the condition has been present for at least several years When the patient was first seen at the hospital there was in the area of the right nipple a scaly and somewhat crusted noninflammatory lesion the size of a dime The diagnosis of carcinoma simplex (Paget's disease) of the nipple was considered At present the entire right nipple and adjoining areola show an infiltrated plaque with an irregular surface

The Wassermann reaction of the blood was negative on Sept 19, 1947 Microscopic examination made by Dr C F Sims, showed that the epidermis was eroded

Bloom There was slight albuminuria and a systolic blood pressure of 180 mm For that reason Dr Jessner thought it wise to discontinue the BAL therapy when the patient had improved

BAL is a powerful drug and one must be careful, particularly in patients with hypertension One good feature is that BAL is rapidly excreted, and the side effects are usually evanescent It is usual for the blood pressure to rise, however, this is variable, and I have often seen the blood pressure fall after BAL injections Because of the effect of BAL on blood pressure Dr Harry Gold of Cornell University expressed the belief that BAL might be valuable in treatment of certain peripheral vascular diseases It is effective also in allergic dermatitis and other conditions produced by certain metals and is often life saving in cases of allergic dermatitis due to mercury and arsenicals I would estimate that only about half of my patients with arsenical dermatitis have shown rapid and unequivocal improvement Theoretically one should expect a favorable response from BAL applied locally However, BAL is a strong cutaneous allergen, hence as a rule one cannot use it as an external application

A Case for Diagnosis (Sarcoid?) Presented by DR MAX BERKOVSKY

A Puerto Rican, aged 60, was admitted to the dermatologic service of the Metropolitan Hospital on March 20, 1947 There appeared on the left thigh a flat, sharply defined lesion the size of a dime, associated with some itching but no pain Similar spots appeared on all four extremities during the next three months The family history revealed that forty years ago the patient was intimately exposed to active tuberculosis in a relative who subsequently died of the disease The patient stated that to his knowledge he never had gonorrhea or syphilis

In 1932 he had an abscess of the left thigh which was opened and drained In 1939 cardiac decompensation developed Digitalis therapy was instituted, and the patient was discharged much improved In the fall of 1946 he was treated at the Harlem Hospital for a cough, and in three months he was discharged as cured He has lost 15 pounds (7 Kg) in the last ten years The only drug that he takes is feen-a-mint® (a laxative containing phenolphthalein) about twice a month

Physical examination reveals a well developed but poorly nourished man The systolic blood pressure is 180 and the diastolic pressure 90 The skin shows many nummular dark brown sharply demarcated flat-topped nodules with some infiltration They are symmetric and not tender and at present involve all four extremities and to some extent the chest and back

The Wassermann, Kahn and Kline reactions of the blood were negative Urinalysis showed no abnormalities Examination of the blood showed 82 per cent hemoglobin, 3,750,000 red blood cells and 12,200 white blood cells, with 40 per cent polymorphonuclear cells, 32 per cent lymphocytes, 15 per cent eosinophils, 11 per cent monocytes and 2 per cent basophils

Roentgenograms of the chest revealed a round shadow the size of a baseball in the region of the left hilus and extending into the anterior mediastinum This was diagnosed as a dermoid cyst, a teratoma or a benign cystic mass Roentgenograms of the hands showed no abnormalities The reaction to the tuberculin test was negative Histologic examination of specimens taken from the left thigh and left arm showed edema and hyalinosis of the papillae with perivascular infiltration of small round cells There was no evidence of tuberculosis The diagnosis from histologic study was chronic dermatitis of unknown cause

in one area Below it there was a large mass made up of groups and strands of basal cells The palisade layer was intact There was a slight inflammatory infiltrate in the midcutis

DISCUSSION

DR CHARLES F SIMS I have examined the slide, and there is no question that it is of basal cell carcinoma

DR HENRY SILVER I suggest that the condition be subjected to the Mohs method of therapy

DR FRANK E CROSS Cancer of the breast in the male is more malignant than is that in the female It is rather uncommon in the male and is usually of the prickle cell type I do not question the histologic report, but in view of the previous statement I feel that one must be more radical in therapy I should, therefore, suggest a wide excision of the nipple, followed by the making of serial sections of the specimen removed for further histologic study

DR CHARLES F SIMS Dr Cross's suggestion of a possible prickle cell epithelioma was not substantiated by the histologic findings

DR NATHAN SOBEL When first seen the lesion was scaly and crusted, and the diagnoses that were considered were chronic eczema, possibly Paget's disease and keratosis of the nipple Tonight the lesion looks clean and somewhat nodular, and it is difficult to make the diagnosis on clinical grounds alone

As Dr Cross stated, basal cell epithelioma of the nipple in the male is a rare condition Dr Arthur Hyman reviewed the literature and could find only the following references to its occurrence Elliott and Welland (ARCH DERMAT & SYPH **53** 322, 1946) reported not a single case of basal cell epithelioma of the nipple among 1,928 cancers of the skin In 1924, Wainright (*Arch Surg* **14** 844, 1927) reviewed 264 cancers of the male breast and found only 1 case of basal cell epithelioma in the series In this series there were only 6 prickle cell epitheliomas, so even prickle cell epithelioma of the nipple is rare Geschickter (Diseases of the Breast, Philadelphia, J B Lippincott Company, 1943, p 603) refers to a reported case of basal cell epithelioma in the female breast mentioned by Ewing Dr Hyman informed me that he has personally seen 1 case of basal cell epithelioma of the male nipple and adjoining areola which was clinically diagnosed as Bowen's disease

After the lesion is removed, serial histologic sections will be studied

FOLLOW-UP NOTE Serial sections showed only basal cell epithelioma

Multiple Pigmented Nevi Presented by DR CHARLES WOLF

Poikiloderma of Civatte Presented by DR HARRY B FEILER

PHILADELPHIA DERMATOLOGICAL SOCIETY

J M Schildkraut, M D, *Chairman*

Herpetic Stomatitis and Vaginitis (Pemphigus?) Presented by DR JOHN F WILSON

Scleroderma with Calcinosis Presented by DR CARMEN C THOMAS and (by invitation) DR DAVID KREMER

DR FREDERICK R SCHMIDT At one time my co-workers and I collected 9 cases of alopecia areata which recurred regularly in September and March of succeeding years, which was apparently a type of arterial spasm, due to poor nutrition of the end arteries

DR E M SMITH JR It would be impossible for the patient to pull out the hair I have seen two recurrences, and they are absolutely the same, in that they run right down the middle of the scalp and extend only to the right side and not the left

Multiple Nevi (Adenoma Sebaceum) (Dermatosis Papulosa Nigra and Fibroma Pendulum) in a Negro Presented by DR E A OLIVER and (by invitation) DR E LORANT and DR A B HENNINGSEN

Lymphoblastoma Cutis with Poikilodermatous Changes Presented by DR F E SENEAR and STAFF

Ainhum of Two Years' Duration in a Negro Aged 66 Years Presented (by invitation) by DR MAURICE OPPENHEIM and DR DAVID COHEN

A Case for Diagnosis (Unilateral Vascular Nevus? Angioma Serpiginosum? Schamberg's Disease?) Presented by DR F E SENEAR and STAFF

Ichthyosiform Erythroderma? Presented by DR S ROTHMAN and (by invitation) DR J H MCCREARY

Localized Myxedema, Pretibial, Following Thyroidectomy Presented by DR F E SENEAR and STAFF

Probable Triple Symptom Complex of Behcet, Scrotal Tongue Presented by DR F E SENEAR and STAFF

A I, a white housewife aged 25, was shown at the December meeting of this society with a condition for diagnosis She gave a five months' history of recurrent ulcerative lesions of the mouth which had not responded to various local treatments or to intravenous treatment for a diagnosis of "trench mouth" made prior to admission At the time of presentation, she showed a marginal scrotal tongue with whitish patches of membrane extending from some of the crypts of the tongue, as well as scattered on the buccal mucous membranes These were relatively easily removed, leaving superficial tender ulcerations without bleeding and surrounded by an erythematous halo Direct examinations did not reveal mycelia During the discussion the following diagnoses were mentioned as possibilities (1) aphthous stomatitis, (2) moniliasis, (3) eruption due to drugs, (4) Behcet's triple symptom complex and (5) scrotal tongue

Medical consultation revealed nothing contributory The urine was normal, blood cell counts were normal, the results of the serologic test for syphilis and examination of the chest were all negative Examination by the gynecologic consultant showed only chronic cervicitis Repeated cultures from the mouth lesions failed to demonstrate Monilia, although cultures from vaginal discharge on one occassion did grow mucoid colonies with budding forms on microscopic examination On one occasion, the patient complained of soreness about the vulva,

and examination in our department revealed superficial ulcerations about the labia minora and majora

On about the first of February, the patient was found to have decided injection of the right conjunctiva diagnosed as episcleritis by the ophthalmologic consultant This was considered consistent with, though not diagnostic of, Behcet's syndrome of the eye She stated that she had had one previous similar, though less severe, attack of ocular inflammation about five weeks ago

Perniones and Livedo Reticularis in a Poliomyelitic Limb Presented by DR F E SENEAR and STAFF

DISCUSSION

DR M R CARO The sections were not typical of tuberculosis or tuberculid, though there were round cells which extended deeply into the fat

DR STEPHEN ROTHMAN I was very much impressed with this case because I saw quite a few after World War I in patients who had nerve injuries It shows what a profound effect trophic ulcers have on vasomotor action

DR J F MADDEN, St Paul In our experience with poliomyelitis, my co-workers and I have noted that the patients have more cutaneous changes than the normal person During the acute stages in which the Sister Kenny method of therapy is used the patient often shows miliaria from the hot applications

DR F E SENEAR When I first saw this patient a couple of weeks ago, I thought that he had an exaggerated example of erythrocyanosis frigida crurum that the English have written about This is the first time I have seen one with so much inflammatory element that it simulated erythema exfoliativa Dr Brunner called our attention to the fact that Telford had pointed out that just this type of reaction does occur, particularly in the wasted limbs of persons who have had poliomyelitis I think, as Dr Rothman indicated, that it is a nerve injury that predisposes to this type of reaction, which is less intense than erythema exfoliativa

Eosinophilic Granuloma? Presented by DR S ROTHMAN and (by invitation) DR J H MCCREARY

Since the age of 2 years, the patient, an 11 year old white girl, has been almost continuously sick with swelling of lymph nodes and with ulceration of the overlying skin on the head, neck and thorax The appearance of each new lesion has been accompanied with a temperature of 99 to 104 F, pain, tenderness, erythema and some swelling over the affected gland The overlying skin became red and shiny until spontaneous rupture occurred A seropurulent exudate appeared, and a crust was formed over a deep crater After rupture of the "abscess," the systemic symptoms disappeared and the temperature returned to normal There is a tendency toward slow healing with granulation and scar formation Since an operation two years ago for the removal of a group of cervical glands, the motion of the shoulders and neck has been restricted because of pain

Just previous to the onset of the present illness, the patient had measles and mumps at the same time During this illness the adenitis of the right submaxillary glands developed This adenitis failed to resolve, and formed an ulcer which persisted over twenty months Abscesses of nearby nodes followed in a similar characteristic course

Roentgen therapy seemed to accelerate healing, with remissions of the symptoms for as long as a year Dosages of the many courses of roentgen rays she received

Blastomycosis with Pulmonary Involvement. Presented by DR CARMEN C THOMAS and (by invitation) DR G H WELLS

Cutaneous Diphtheria Presented by DR CLARENCE S. LIVINGOOD and (by invitation) DR HARVEY BLANK

C L, a white man aged 25 years, presents healed, round scars on both legs, approximately 1 inch (2 cm) in diameter, with brownish, pigmented, atrophic centers On July 10, 1944, five weeks after the patient's arrival in Burma, ulcers appeared on both legs On August 3 he was admitted to the 69th General Hospital, Assam, India, with multiple, punched-out ulcers with a tough black eschar and a rolled bluish red border On October 1 numbness and weakness of the fingers, toes, hands and feet appeared By October 31 the skin had healed, and by December 30 the neuritic symptoms had cleared

The smears taken from the ulcers did not show fusiform bacilli or spirochetes Cultures were not available, but virulent Corynebacterium diphtheriae were cultured from many other patients with the same type of lesion

The patient was treated with various bland local measures and bed rest As the result of his Schick test was negative, no antitoxin was given

DISCUSSION

DR CLARENCE S LIVINGOOD This is a patient whom Dr Blank saw from the onset of his illness The scars are typical postdiphtheritic ones Other ulcerative lesions can leave scars, but with experience one can identify the postdiphtheritic type We had difficulty in convincing our colleagues that cutaneous diphtheria produced ulcers that are diagnostic Any dermatologist who is accustomed to seeing and making fine distinctions between ulcerative lesions can make this diagnosis without difficulty Anthrax, first degree burns and trophic ulcers can produce somewhat similar scars, but I do not believe that any other conditions produce ulcers of this type

A Case for Diagnosis (Poikiloderma Atrophicans Vasculare?). Presented by CAPTAIN ROBERT L GILMAN, United States Navy

Parapsoriasis en Plaques Presented by DR LEWIS M JOHNSON

R J, a white man aged 19 years, noticed an eruption on his lower extremities shortly after an attack of severe bronchitis in the spring of 1945 There have been no subjective symptoms The lesions started as small macules and gradually progressed in size and number and occurred on his upper extremities together with an associated loss of pigment During the summer of 1946 the eruption on his upper extremities faded considerably, but recurred during the past winter The history reveals no prolonged ingestion of drugs prior to the onset of the eruption except for "drops" for his heart The patient is well built and presents variously sized, round and oval, pinkish to copper-colored, macular lesions, some of which have a fine scale and a reticulated appearance They are more profuse on the lower extremities, those on the upper extremities have an associated patchy loss of pigment in the surrounding skin These lesions, when viewed with filtered ultraviolet rays ("black light"), are darkened and more pronounced on the lower extremities and have a faint fluorescence on the upper extremities The results of the rest of the physical examination were essentially normal except for a soft mitral systolic murmur, a chronic macerated and fissured eruption between the toes of both feet and hyperhidrosis of the hands and feet

DR J M SCHILDKRAUT Port wine stains are notorious for their failure to respond to roentgen rays But Dr Pfahler and I have recently had infants with such lesions that did respond and we are of the opinion that if radiation is used early these lesions may respond

Sarcoid Solitary Lesion on the Nose Presented by DR CARROLL S WRIGHT and DR E R GROSS

Acne and Comedos in an Infant 8 Weeks of Age Presented by DR. H H PERLMAN

Tuberculosis Verrucosa Cutis on the Neck. Presented by DR MEYER L NIEDELMAN

Reuben Friedman, M D, *Chairman*

Douglass A Decker, M D, *Secretary*

Nov 21, 1947

A Case for Diagnosis (Cutaneous Diphtheria?) Presented by DR LEWIS M JOHNSON (Lancaster, Pa)

A M B, a white woman aged 28, presents a healing ulcer in the right lower quadrant of the abdomen, early necrotizing lesions on the inner side of the left thigh of three days' duration and numerous depressed scars on the left wrist, on the left breast, in the left groin, on the left leg and on the left side of the abdomen She also has a tumor on the left lower part of the back

The present condition developed on Oct 12, 1946, with a "red spot" on the left wrist which formed a blister, turned black, ulcerated and healed, leaving a deep scar Since then other similar lesions have developed When the ulcers develop, she sometimes has painful joints, malaise, nausea and severe menstrual cramps

The serologic tests for syphilis were negative A complete blood count revealed 76 per cent hemoglobin, 3,620,000 erythrocytes, 7,200 leukocytes, 75 per cent polymorphonuclear leukocytes, 23 per cent lymphocytes, 1 per cent monocytes and 1 per cent eosinophils

The microscopic examination of the biopsy section revealed a focus of incomplete necrosis involving essentially the stratified squamous epithelium and its immediate underlying connective tissue This reaction was associated with an inflammatory cell infiltration consisting essentially of eosinophils, plasma cells, lymphocytes and a few polymorphonuclears (neutrophils) This infiltrate occurred chiefly about the blood vessels in the subepithelial areas In some areas the walls of the blood vessels showed a similar infiltration There was also a granulomatous reaction resembling a foreign body reaction Numerous foreign body giant cells appeared in these lesions, and in many instances they contained greenish crystals New blood vessel formation was a prominent feature and appeared to be demarcating the area of necrosis The diagnosis was necrosis of the skin

DISCUSSION

DR CLARENCE S LIVINGOOD This could be cutaneous diphtheria. It might be a factitial eruption caused by an escharotic chemical, such as phenol or saponated cresol solution, but from a clinical standpoint the most likely diagnosis

A complete blood cell count revealed 93 per cent hemoglobin (14 73 Gm), 4,870,000 erythrocytes, 11,600 leukocytes, 71 per cent polymorphonuclear leukocytes and 29 per cent lymphocytes The result of the Kline test of the blood for syphilis was negative The potassium hydroxide preparation of the scales did not reveal fungi A urinalysis showed no abnormalities

DISCUSSION

DR MEYER L NIEDELMAN I suggest the diagnosis of erythema multiforme perstans The lesions have been present for two years, are sharply marginated and on diascopic pressure become rather light, and the surrounding tissue seems to have some pitting edema

DR FRITZ CALLOMON (by invitation) The diagnosis of parapsoriasis appears acceptable This form corresponds to Brocq's erythrodermie pityriasique en plaques disseminees and the yellowish color with the English description of Radcliffe Crocker's xanthoerythroderma perstans Although the lesions of Brocq's disease usually persist unchanged over many years, seasonal changes were observed by Civatte, White and Brocq himself, who described obvious remission during the summer and exacerbation during the winter months (Jadassohn, J Handbuch der Haut- und Geschlechtskrankheiten, Berlin, Julius Springer, 1928, vol 7, pt 1, p 388)

DR BERTRAM SHAFFER This eruption has a peculiar artificial appearance I suggest the diagnosis of factitial eruption The lesions are sharply demarcated and regular, and all of them are disposed on parts of the body accessible to the patient

DR DONALD M PILLSBURY I agree with Dr Shaffer The pharyngeal and corneal reflexes are absent Some of the lesions have disappeared, which is against the diagnosis of parapsoriasis If it turns out that the patient has parapsoriasis, I suggest a trial of anthralin to the point where it produces some reaction This case is similar to one Dr Kulchar had in our clinic some years ago, the only one of parapsoriasis which cleared up with treatment with anthralin (dihydroxyanthranol)

DR LEWIS M JOHNSON, Lancaster, Pa I cannot agree that the patient produced the lesions on the backs of the arms, nor can I understand the depigmentation I thought of a fixed type of eruption when I saw him first in November I shall let you know the report of the biopsy

NOTE—The diagnosis from the biopsy was parapsoriasis (Lancaster General Hospital)

Sporotrichosis Presented by DR J M SCHILDKRAUT, Trenton, Pa

Recurrent Lupus Erythematosus Presented by DR H E TWINING

J C, a Negro man aged 30 years and well nourished, presents sharply marginated, eczematous, slightly scaly patches of dermatitis on the cheeks, nose and mucous membranes of the mouth of about four months' duration The original lesions almost completely disappeared with treatment with bismuth subsalicylate injections and liver This is the third recurrence, all the lesions appearing at the original sites A small, erythematous area developed on the bridge of the nose in 1943 This was diagnosed as eczema Three months later it recurred with erythematous scaly lesions sharply demarcated on the nose and cheeks

A roentgenogram of the chest did not show tuberculosis Treatment with injections of bismuth compound and liver was successful in previous attacks but produced no improvement in the present one

is cutaneous diphtheria The patient has numbness and tingling of her hands and some weakness She had a severe sore throat about two months after the first lesion developed I suggest careful bacteriologic studies on the most recent lesion, done with the full realization that it is difficult to isolate the Klebs-Loeffler bacillus from the skin even when it is present A spinal fluid examination should be done, and if the patient has an elevated spinal fluid protein, it would lend weight to the thought that the numbness and tingling of the hands represent a neurologic complication of the cutaneous diphtheria

DR DONALD M PILLSBURY I saw this patient after Dr Livingood did, and our initial joint reaction was that culture for corynebacterium diphtheriae was indicated The usual sharp borders of a factitial eruption produced by an escharotic are also characteristic of many diphtheritic ulcers of the skin, and the differentiation may be difficult I suggest, in addition, very careful clinical study from the standpoint of peripheral neuritis or other late changes due to diphtheria toxin If any further collateral evidence of diphtheria is uncovered and if a factitial origin can be ruled out, I suggest administration of diphtheria antitoxin, even if the cultures are negative As has been pointed out, recovery of the organism may be difficult in the hands of even the most experienced bacteriologist, especially when the lesion is old or when local treatment, such as applications of penicillin, has been given

Sulzberger-Garbe Disease (?) (Exudative Discoid and Lichenoid Dermatosis) Presented by DR LOUIS GOLDSTEIN and (by invitation) DR J FERNANDEZ

H K, a white man aged 43, presents papulomacular eruptions on the trunk and extremities which are retiform in character The papules are large, flat topped and reddish-yellow or darker, with mild scaling The patient has had attacks of this condition since 1930 He was hospitalized in April 1947 for an intensely pruritic dermatosis of several months' duration He was discharged much improved after three weeks of treatment Several days after discharge the dermatosis recurred, and he was again hospitalized for five weeks and was discharged much improved Several days later the condition recurred again, and it has remained until the present time

A urinalysis showed occasional leukocytes, epithelial cells and some mucus Complete blood counts revealed 3,890,000 to 4,060,000 erythrocytes, 10,000 to 14,000 leukocytes, 60 to 82 per cent polymorphonuclear leukocytes, 16 to 33 per cent lymphocytes, 1 to 2 per cent monocytes, and 8 to 15 per cent eosinophils The blood sugar was 99 mg per hundred cubic centimeters of blood The urea nitrogen was 13 5 mg The serologic tests for syphilis elicited negative reactions On April 21, 1947, Dr Weidman reported the biopsy specimen to show psoriasis

The patient has been treated with coal tar solution N F, boric acid, amobarbital sodium (sodium amytal®), tripelennamine hydrochloride (pyribenzamine hydrochloride®), protein hydrolysate, starch baths and bismuth sodium triglycollamate (bistrimate®), with improvement

DISCUSSION

DR CHARLES R REIN, New York (by invitation) I agree with the diagnosis

DR MAX JESSNER, New York (by invitation) This condition was unknown in Europe but I have seen many cases in New York I suggest that the patient be treated with arsenic or be sent to Arizona, where most of these eruptions clear up

DISCUSSION

DR CHARLES R REIN, New York (by invitation) I have used bismuth sodium triglycollamate (bistrimate®) in a number of conditions, including lupus erythematosus, lichen planus, verruca and granuloma annulare Best results were obtained in patients with lupus erythematosus Two patients with this condition showed no improvement after many intramuscular injections of bismuth subsalicylate but responded well to oral treatment with bismuth sodium triglycollamate This preparation was also efficacious in some patients with acute generalized lichen planus, but the results in the other diseases were disappointing

DR H E TWINING I tried bismuth sodium triglycollamate in this patient but had to discontinue it because of the occurrence of stomatitis and gingivitis Has Dr Wright seen many patients who cannot tolerate this drug?

DR CARROLL S WRIGHT My co-workers and I have the same percentage of intolerance with this preparation as with bismuth given in any other form

DR MEYER L NIEDELMAN At the last Atlantic Dermatological Conference suramin sodium (naphuride®) was mentioned for the treatment of lupus erythematosus It would be worth while to try it in this patient, if bismuth preparations prove ineffective

DR STEPHEN WHELAN (by invitation) In a total of about 25 patients with discoid lupus erythematosus my co-workers and I have used bismuth sodium triglycollamate in the past year and a half and we have not had the favorable results that Dr Wright and Dr Gross have reported We had 2 cases of hypertrophic lichen planus with good results in which the disease had not responded to bismuth compound administered intramuscularly

Multiple Large Keloids. Presented by DR MEYER L NIEDELMAN

E R, a white man aged 25 years, has a large, thick, keloidal band on his neck It is lobulated and adherent and limits the motion of the chin There are a number of small keloids on the cheek, chest, back and arms and on the vaccination site There are no lesions on the lower extremities On the forehead, cheeks and nose there are numerous hyperpigmented macules from pinpoint size to pea size, which the patient stated have been present since birth He had a burn from hot water on the neck at the age of 8 years, the past history is otherwise normal At the age of 12 the patient first noticed the keloids about the neck Shortly thereafter papules developed on the right side of his face, which subsequently developed into keloids He sustained a human bite on the sternal area at the age of 16, which developed into a keloid

In 1943, at another institution, the entire keloid on the neck was surgically removed, sutured and treated with roentgen rays This region shortly grew larger than the original In 1944 the keloid on the left side of the neck was similarly treated, that on the right side of the neck was operated on in September 1944, with a skin graft from the right thigh A keloid developed at the donor site

DISCUSSION

DR. J P SCULLY (by invitation) This patient shows two different types of scar The question arises whether endocrine disturbances are a factor in the production of keloidal change and whether, if further surgical attempts were made in this case, it might be well to attempt the coincident injection of diethyl

DR STEPHEN T WHELAN What type of arsenic does Dr Jessner use?

DR MAX JESSNER, New York (by invitation) I inject a 1 per cent solution of arsenic trioxide with 2 per cent phenol, starting with 0 25 cc daily and increasing to 1 cc daily

DR CLARENCE S LIVINGOOD I have no better diagnosis to offer than Sulzberger-Garbe disease, but I always feel dissatisfied with that diagnosis This patient is similar to one of mine whose eruption cleared up, partly because of hospitalization and partly because of therapy of various types The most notable thing about his course was that there would be a flare-up following an infection of the upper respiratory tract or the injection of an autogenous vaccine in a very small dose

Mycosis Fungoides Presented by DRS CLARENCE S LIVINGOOD and (by invitation) J P SCULLY

W B, a white man aged 82, was first seen on Oct 7, 1947, with the chief complaint of "sore on the back" which had been present for four or five months The process was said to have begun as a "small pimple" between the scapulas which the patient attributed to an insect bite received at the seashore At the time of the first visit, the patient presented a firm, reddish, indurated lesion measuring 4 fingerbreadths in diameter, between the scapulas The center was slightly raised and purplish, but gave no evidence of breakdown of tissue or fluctuation During a subsequent period of two weeks' observation, some exudation and a suggestion of superficial breakdown of skin were evidenced Three weekly injections of 300,000 units of penicillin in oil and wax were without effect on the process

The general physical examination disclosed nothing significant except a palpable liver edge 2 fingerbreadths below the costal margin There was no splenomegaly and no generalized or localized adenopathy The patient complained only of slight itching

The results of urinalysis were normal The serologic tests for syphilis elicited negative reactions A complete blood count revealed 79 per cent hemoglobin, 3,950,000 erythrocytes, 7,750 leukocytes, 58 per cent neutrophils, 3 per cent eosinophils, 34 per cent lymphocytes and 5 per cent monocytes, the color index was 1 01

Biopsy was reported to indicate lymphoblastoma and probable mycosis fungoides (The punch biopsy wound healed promptly)

The patient was given 600 r of roentgen rays in doses of 100 r over a period of sixteen days Exudation ceased after the second treatment, the induration regressed and the lesions flattened within two weeks

DISCUSSION

DR FRED D WEIDMAN When I first looked at the lesion, I thought that it might be Bowen's disease that had been overtreated The sections show that there is a reticuloendothelial disease, but I cannot quite make myself think that it is mycosis fungoides The epidermal changes are not sufficiently hyperplastic I think that it would come closer to being Spiegler-Fendt sarcoid, even though clinically that diagnosis would not quite fit But there are many of these reticuloendothelial disturbances that cannot be forced into some particular niche or pigeonhole that dermatologists have made Just as in Hodgkin's disease, there are atypical cases, and I think that this is one of them I cannot go further than to say that it is an abnormality of the reticuloendothelial system perhaps closer to Spiegler-Fendt sarcoid than to anything else

stilbestrol or male sex hormone during the postoperative period It was suggested that one lesion, possibly the one on the sternum, be excised in trial treatment and then some type of therapy determined In one case irradiation was suggested I should like to see diethyl stilbestrol or some similar preparation tried in order to determine whether the keloidal aftermath might be prevented

DR IRA L SCHAMBERG Are keloids ever seen before puberty? Children suffer all sorts of trauma, and, if they are not seen, Dr Scully's suggestion has some merit

DR DONALD M PILLSBURY I have seen many keloids in children

DR MAX JESSNER, New York (by invitation) I had a keloid when I was a small boy, but not since then Keloid formation is due to a "fibrotic" tendency of the organism, and that may change I do not believe that we know the reason for this, but many things have been suggested There has been a report by a physician who cured keloids by the administration of sodium fluoride (Callam, M *Munchen med Wchnschr* **82** 1534, 1935) I tried it in a case and had the impression that it did good I was afraid, however, to give it in large doses

CAPTAIN ROBERT L GILMAN, United States Navy I have seen keloids in children 4 to 8 years of age

DR THOMAS BUTTERWORTH, Reading, Pa Keloids do occur in children I am treating a keloid now in a youngster The statement occurs in some books that keloids tend to undergo involution after the menopause I have seen a keloid develop in the breast of a school teacher about 55 years of age For the case presented today I recommend Dr H J Smith's 2 per cent menthol in cottonseed oil with massage

DR DOUGLASS A DECKER, Allentown, Pa Dr Smith stated that the menthol and cottonseed oil preparation helps only those patients with itching or pain in the keloid

May 16, 1947

Psoriasis, with Extensive Koebner Phenomenon Induced by Systemic Reaction to Sulfadiazine Applied Locally to Burn Presented by DR LESLIE NICHOLAS and (by invitation) CAPTAIN RAYMOND R SUSKIND

Trichophyton Purpureum and Monilia Infection of the Hands, Feet and Nails Moniliasis of the Tongue Presented by DR LESLIE NICHOLAS and (by invitation) CAPTAIN RAYMOND R SUSKIND

Pigmented Purpuric Lichenoid Dermatitis Presented by DR LOUIS GOLDSTEIN

S W, a white man aged 29 years, presents on both legs many smooth, small, slightly elevated papules, some of which fuse into poorly marginated patches They are reddish brown The condition began about six months ago on the lateroanterior aspect of the left leg as a reddish, flat, papular, quarter-sized lesion with no subjective symptoms and gradually progressed to the present size

DR. MAX JESSNER, New York (by invitation) It is impossible to make a histologic diagnosis in the early stage of mycosis fungoides, since there is nothing characteristic histologically at that time Dr John Garb is treating patients with mycosis fungoides with antimony potassium tartrate U S P, and the results have been astonishing The patients react promptly to the therapy

DR J P SCULLY (by invitation) The diagnosis was made by exclusion I could think of no other lymphoblastoma that would produce no other systemic manifestations without other evidence of disease and persist for six months

Extensive Pityriasis Lichenoides et Varioliformis Acuta (Mucha-Habermann) Presented by DR REUBEN FRIEDMAN and (by invitation) DR HERBERT KAPLAN and DR JOHN B ROXBY JR

DISCUSSION

DR DONALD M PILLSBURY This is an unusually extensive and good example of this disease Whenever I see a patient with this disease, I am amazed that it can be so confidently classified in the textbooks in the parapsoriasis group There are many features of it which suggest a subacute infection, or at least a local reaction to the products of some infection I should like to hear Dr Blank discuss whether or not any such cases have been studied from the standpoint of a virus origin, I do not recall any such reports

DR HARVEY BLANK (by invitation) As far as I know, this particular disease has not been investigated recently along those lines At the moment, one of the means of investigation of such a case is to put the vesicle material directly on the little screens to be used in the electron microscope, and it is now possible within a matter of hours to differentiate smallpox from chickenpox Dr Geoffrey W Rake, of the Squibb Institute, has worked this out in considerable detail and is interested in material from any questionable case

DR. REUBEN FRIEDMAN Fluid from several of the vesicles was inoculated into the scratched cornea of a rabbit, with a negative reaction

DR LOUIS GOLDSTEIN Did this patient have lesions in the oral cavity in the acute stage?

DR REUBEN FRIEDMAN No Three days ago papular hemorrhagic lesions developed on the roof of the mouth and pigmented petechial lesions on the palms and soles

Multiple Recurrences of Infectious Syphilis Over Nineteen Years, Granuloma Inguinale Presented by DR HERMAN BEERMAN and (by invitation) DR MORTIMER S FALK

P D, a white man aged 40, presents pinkish verrucous-appearing hypertrophic growth on the ventral surface of the coronal sulcus, negative for Treponema pallidum on dark field examination The patient had primary dark field-positive syphilis in February 1928 He was treated with arsenical and bismuth preparations Dark field examinations were made on several occasions—December 1930, November 1932, April 1934 and November 1938, all with positive results (This case was first reported by Pariser [*J A M A* **113** 1206 (Sept 23) 1939]) The original lesion, however, did not heal completely at any time Granuloma inguinale was suspected as early as 1934 and a few injections of antimony potassium tartrate were

DISCUSSION

DR FRED D WEIDMAN I think we were all struck by the extremely lurid color of these lesions, in six months there certainly ought to be some pigmentation, yet there is not In the sections there is not any sign of hemorrhage to explain the extreme redness nor is there any pigment One must explain the redness on some other basis than that, and it is known that sometimes infiltrations of cells will produce a red color, for example, the small red kidney in chronic interstitial nephritis There is not any particular vascular hyperplasia, and there is no hemorrhage, but there is something different in the constitution of the cells which in the aggregate makes them red That was one of the things that puzzled me in this case Microscopically certain features suggest lichen planus, like the sharp demarcation of the zone underneath, but cellular infiltration is sparse for that, considering that these are fresh lesions, yet they are so highly elevated and delicately nodular or papular They are not in a regressive stage They are not atrophic lesions If this were lichen planus it would have to be atrophic lichen planus, and that is contrary to what this patient presents There are many histiocytes, and I do not know what the significance of those may be except that they tend to assist in eliminating lichen planus as a diagnosis The grouping is not discoid, as it should be in Majocchi's disease, and the lesions are not hemorrhagic In this type there should be some pigmentation There is a slight scaliness, but in the Gougerot-Blum complex I think that there should be more scaliness than is shown here I think that this is a puzzling case, and I cannot give a specific diagnosis

A Case for Diagnosis (Leukemia?) Presented by DR THOMAS BUTTERWORTH, Reading, Pa

Extensive Verruca Plantaris, Verruca Vulgaris Presented by DR J M SCHILDKRAUT, Trenton, N J

DISCUSSION

DR C S LIVINGOOD I suggest that the patient soak his feet daily in a solution of formaldehyde It is well to use 4 per cent formaldehyde for only a minute or so at first and gradually increase the time to four or five minutes, depending on the reaction

DR THOMAS BUTTERWORTH, Reading, Pa I often advise patients to apply 60 per cent salicylic acid paste and bandage the foot for about three days and then rub in 30 per cent salicylic acid paste nightly with the round head of a clothes pin, this seems to be effective

DR ISADORE ZUGERMAN Has the patient had bismuth sodium triglycollamate?

DR J M SCHILDKRAUT, Trenton, N J He has had bismuth subsalicylate injections

DR THOMAS BUTTERWORTH When treating a patient with formaldehyde solution, one must be sure that the fluid is not much more than a ¼ inch (0 64 cm) deep

Tuberculosis Verrucosa Cutis Presented by DR SIMON KATZ and (by invitation) DR PETER HORVATH

Trichophytosis Barbae Presented by DR M H SAMITZ and (by invitation) DR LAWRENCE KATZENSTEIN

Résumé of Clinical Course

Date	Number of Injections	Drug	Serologic Reaction	Progress Note
2/29/28	. .	....	Kolmer 44 Kahn positive	Dark field-positive penile lesion
2/29/28-12/20/28	7	Arsphenamine Bismuth arsphenamine sulfonate	Kolmer negative	Patient lost from observation
9/19/30-9/25/30	2	Neoarsphenamine	Kolmer negative	Dark field-positive penile lesions
2/12/32 2/26/32	3	Bismuth subsalicylate	Kolmer negative	No clinical relapse
11/21/32	9	Trisodium arsphenamine sulfonate	Kolmer negative	Indurated, ulcerative penile lesion swarming with spirochetes, lesion was at same site as original monorecidive
1/19/33	9	Trisodium arsphenamine sulfonate, bismuth subsalicylate	Kolmer negative	
6/15/33 12/8/33	. 10	Trisodium arsphenamine sulfonate		Glans penis inflamed, ulcerative lesion
	10	Bismuth subsalicylate		
4/17/34 3/20/36	20	Trisodium arsphenamine sulfonate	Kolmer 00	Lesion on left side of glans penis, dark field-positive for T pallidum
	26	Bismuth subsalicylate	Kolmer 44 on 5 tests, 10/11/35 to 1/16/36	
8/13/34	3	Antimony potassium tartrate	Negative (cerebrospinal fluid) 1/24/36	On 6/19/34 inoculations (rabbit) were reported positive for T pallidum, lesion did not respond to therapy, possibility of granuloma inguinale considered
2/7/35	8	Fuadin®	Kolmer 44	Dark field-positive perianal condyloma and multiple indurated purulent secreting penile ulcers, condyloma healed under treatment
11/1/38	8	Arsphenamine	..... .	
8/1/39	3	Bismuth subsalicylate	Kolmer 44	
11/7/38	.	.. .		Ducrey test positive, Frei test negative
1/28/42 2/9/42	3	Bismuth subsalicylate	Kolmer positive	Patient returned with granulomatous lesion on frenulum which he stated had been present since original visit (14 years), dark field-negative for T pallidum, smear revealed presence of Donovan bodies
	3	Antimony potassium tartrate		
2/47	60	Penicillin, 2,400,000 units	Negative	Dark field-positive primary syphilis (diagnosed and treated in another institution)
10/2/47	.		Kolmer negative Kline negative	Patient returns with verrucous-appearing hypertrophic growth on ventral surface of coronal sulcus, dark field-negative for T pallidum
10/3/47	. . .			Biopsy granuloma inguinale

Pityriasis Rubra Pilaris Presented by DR CARROLL S WRIGHT and DR MEYER L NIEDELMAN

E F, a Negro woman aged 39 years, first had a severe sore throat and a painful right shoulder about two months ago She used a gargle several times daily, consisting of a solution of 1 teaspoonful of salt and several drops of iodine About two weeks ago swelling of the face, puffiness of the eyes and scaling of the scalp developed The eruption on the arms and body followed After the eruption appeared she received several injections of an unknown substance There is an acute inflammatory dermatitis of the face and edema of the periorbital areas with pronounced conjunctivitis The scalp and other hairy areas show scaliness On the extensor surfaces of the arms, shoulders, nucha and legs is a widespread discrete follicular keratotic eruption There is little itching There is no history of ingestion of drugs The Wassermann reaction of the blood for syphilis was negative

DISCUSSION

DR. HERMAN BEERMAN This is lichen planus

DR STEPHEN T WHELAN (by invitation) Some manifestations of the disease are incompatible with the diagnosis of lichen planus The process began on the face with edema and scaling, shortly after the patient had been to the hair dresser She also has scaling on her palms This is an allergic reaction to something that has been applied to the patient's hair

DR. C S LIVINGOOD Both Dr Beerman and Dr Whelan are right The patient has a Koebner phenomenon at the sites of her shoulder straps She may have both contact dermatitis and lichen planus

DR MEYER L NIEDELMAN Pityriasis rubra pilaris may have an acute explosive onset, it may start on the scalp and travel to the face I believe that this is a case of pityriasis rubra pilaris with a sudden and acute onset The patient has had no medication and has gone to the beauty shop many times before, with no ill effect The plugs and the involvement of the hairy areas are in accord with that diagnosis

DR D M SIDLICK I do not recall seeing in any reports or textbooks pityriasis rubra pilaris characterized by lichenoid lesions, and, if this is such a case, we shall have to change our concept once again

DR FRED D WEIDMAN There is a condition known as lichen planopilaris, maybe that would reconcile the different diagnoses that have been advanced In the histologic sections it was found that the lichen planus changes do extend down around the hair follicles, making them unduly prominent At the Naval Hospital there was a patient who had a patch of hypertrophic lichen planus on the thigh, and in one there were definite pits, which made me think at first of those which occur when one pulls out a plug from a lesion of Darier's disease These were located at the orifices of hair follicles I would suggest that the patient be examined with respect to a diagnosis of lichen planopilaris, which would bridge the two separate diagnoses advanced

DR LOUIS GOLDSTEIN I thought that lichen planopilaris had to do with the scalp and not with the glabrous parts of the body

DR. HERMAN BEERMAN The typical lesions of lichen planopilaris do occur on the wrists usually

NOTE—Microscopic examination of a biopsy specimen by Dr Fred D Weidman and by Dr Ernest Regertis resulted in a diagnosis of pityriasis rubra pilaris

given In February 1947, dark field-positive primary syphilis was diagnosed at another institution, and the patient was given 2,400,000 units of penicillin According to the patient, the lesion did not heal

DISCUSSION

DR DONALD M PILLSBURY I did the original dark field examination on this patient in February 1928 As the history indicates, for many years thereafter, in spite of what was presumed to be good antisyphilitic treatment, lesions of early syphilis, from which T pallidum was recovered, continued to develop on his skin The patient apparently now has granuloma inguinale, but I would not doubt the capacity for infectious lesions of early syphilis to develop even now, in view of the past history A picture which I cannot get out of my mind in connection with this patient is that of rows on rows of filing cases in the Department of Medicine and Surgery of the Veterans Administration, all containing the records of men treated for syphilis in the Armed Forces Many of these have received penicillin therapy and, in the year 1945 at least, penicillin of very doubtful antisyphilitic potency When one observes relapses and/or reinfections after penicillin therapy and patients such as this one, the enormous potentialities of such patients in terms of the public health are very apparent Syphilis is far from being well controlled, and our methods to this end are still not so effective as they should be

DR DOUGLASS A DECKER, Allentown, Pa This is the first time that I have seen a white patient with granuloma inguinale

DR HERMAN BEERMAN I have seen this patient for nineteen years I can concur in the statement that he had a positive dark field examination in 1928 and that we obtained positive inoculation in rabbits with a portion of his penile lesion in 1934, even in 1934 we thought that he had granuloma inguinale, and he received some injections of antimony potassium tartrate then Every time that Dr Stokes wanted a dark field-positive lesion for teaching purposes he used to say "Get that boy" I think the primary diagnosis now is granuloma inguinale There were Donovan bodies present

FOLLOW-UP NOTE The patient was given 20 Gm of streptomycin intramuscularly in five days (Nov 25 to 30, 1947) The lesions healed promptly, without recurrence to date (October 1949)

A Case for Diagnosis (Senear-Usher Syndrome? Pemphigus Vulgaris?)

Necrobiosis Lipoidica Presented by DR H J PARKHURST, Toledo, Ohio

K D R, a married woman aged 39, presents on the inner aspect of the lower right shin a large coin-sized morphea-like patch of four years' duration, with sharp borders and some scaling of the surface The ivory-colored center shows telangiectases, and toward the border the tint was violaceous On the dorsum

Scleroderma in an Infant. Presented by DR J. M. SCHILDKRAUT, Trenton, N J.

A B, an infant 1 week of age, has had an eruption on the back since birth Examination shows hard, infiltrated plaques on the upper part of the back, anterior aspect of the chest and the right cheek

DISCUSSION

DR. CARMEN C THOMAS I suggest the diagnosis of subcutaneous fat necrosis of the newborn The lesions were present at birth, after a difficult labor lasting a day and a half, with delivery finally accomplished by forceps The lesions are deep seated, with the periphery beginning to show gradual involution

DR D M SIDLICK Scleroderma in an infant 1 week old would be accompanied by clinical evidence of systemic involvement The tense, edematous skin as well as the distribution and its presence since birth are more in consonance with the diagnosis of scleredema than scleroderma

DR FRED D WEIDMAN I offer an alternative diagnosis of lipophagic granuloma

DR J M SCHILDKRAUT, Trenton, N J Dr Klauder thought that the patient had scleroderma

DR H H PERLMAN I have seen a good many cases of so-called subcutaneous fat necrosis in the newborn The condition is usually described as sclerema neonatorum by many writers (misnomer) The mother stated that she had had an unusually difficult and prolonged labor It is for this reason that trauma should seriously be considered as a causative factor The condition appears a few weeks after birth and invariably disappears spontaneously, usually after a few months Someone mentioned sclerema neonatorum I do not think that this is a case of sclerema neonatorum, because that is a congenital condition or appears soon after birth (usually between the second and tenth day after birth) The condition affects the lower extremities and then spreads to the trunk In sclerema neonatorum, on pressing the affected sites one gets the impression that one is prodding the skin of a cadaver, the skin feels like half-frozen tissue Most patients with such a condition die early The lesions are rather extensive in this case, which is strongly in favor of subcutaneous fat necrosis If this is not a case of subcutaneous fat necrosis, then I would endorse the diagnosis of scleroderma

Douglass A Decker, M D, *Secretary*

Sept 19, 1947

Multiple Benign Cystic Epithelioma in a Girl Aged Eight Years. Presented by DR LEWIS M JOHNSON, Lancaster, Pa

A Case for Diagnosis (Angioma?). Presented by DR JOHN F WILSON

A J, a white woman aged 49 years, has a group of small red papules in the middle of the flexor surface of the left forearm The color can be pressed from the lesions, and the intervening skin is erythematous In August 1945, the patient had an appendectomy and right oophorectomy for simple ovarian cyst and appendicitis In April 1947, an exploratory laparotomy and transverse colostomy

of the left foot is a cluster of pea-sized brownish erythematous nodules grouped in a circle the size of a large coin These appeared after she had returned from Florida a week ago

Urinalysis and blood sugar studies showed no diabetes, and there was no family history of that disease

DISCUSSION

DR HARTHER KEIM The recent lesion on the left foot and the older one on the right foot look like granuloma annulare I wonder whether the large lesion on the shin is not the same

DR LOREN SHAFFER I agree with Dr Keim that this is a granulomatous process The older lesion is hardly typical of necrobiosis, because of the elevated border The youngest lesion has developed so quickly that it may be erythema diutinum Biopsy is indicated

DR ARTHUR JAMES The margin of the large lesion resembles granuloma annulare, the center looks like necrobiosis lipoidica

DR FELIX PINKUS The lesion looks like granuloma annulare, but everything on the legs below the knees is suggestive of necrobiosis

DR HARTHER KEIM We should keep in mind the case of Dr Belote's in which the disease later turned out to be ulcerating tuberculosis

DR HENRY BRUNSTING One must consider lipid disturbances of other types

DR HOWARD PARKHURST I am sorry that no biopsy could be done The lesion looked more typical when I saw the patient first, several months ago, and this is only the second time I have seen her The appearance of the patch has changed, possibly owing to the roentgen treatment she has received The lesions on the left foot are different, possibly due to insect bites, because she was in Florida, a week ago, when they suddenly appeared

Lupus Erythematosus Limited to the Lips and Buccal Mucosa in a Woman Aged 37, Duration Nine Years Presented by DR H J PARKHURST

Lupus Erythematosus of Mucous Membrane of the Lips and Buccal Mucosa in a Man Aged 37, Duration Eleven Years Presented by DR HENRY A BRUNSTING

Discoid Lupus Erythematosus of the Nose in a Woman Aged 41, Duration Fourteen Years Presented by DR HENRY A BRUNSTING

Two Cases of Congenital Ectodermal Defect (Incomplete) Presented by DR H J PARKHURST

Circumscribed Scleroderma Presented by DR ARTHUR JAMES

Circumscribed Scleroderma of Six Weeks' Duration (Scleredema?) Presented by DR ARTHUR JAMES

Multiple Idiopathic Hemorrhagic Sarcoma of Kaposi Presented by DR HENRY A BRUNSTING

J H, a Negro aged 61, first noticed small tumors on the soles of both feet about 1940 These have progressed to involve the entire right sole and toe and the left instep

were performed for postoperative adhesions and diverticulitis of the middle part of the sigmoid In August 1947, resections of the sigmoid were done for adenocarcinoma with metastasis to the regional lymph nodes The patient noticed a small red spot in the middle of the left forearm a year ago This remained about the same until May 1947 After an exploratory laparotomy the lesion spread, the present eruption has existed for several months

A blood cell count revealed 78 per cent hemoglobin, 4,300,000 erythrocytes and 6,000 leukocytes The urine was normal The Wassermann and Kahn reactions of the blood were negative The blood urea nitrogen was 13 2, plasma proteins 6 15, albumin 4 29 and globulin 1 9

DISCUSSION

DR FRED D WEIDMAN I think that it is necessary to see the sections for the diagnosis They show clearly the structure of a capillary angioma It is not a solitary large tumor, but there are microscopic puncta in the tissues The neoplasm is scattered throughout the section There is a good deal of hyperplasia of the endothelium More of the epithelium seems to comprise the bulk of the lesion than the blood vessels Perhaps that is why the lesion does not appear to be particularly red The patient has had this, I understand, for five years, which would point to the diagnosis of angioma rather than angiosarcoma A general pathologist from the sections might diagnose this as an angioendothelioma proliferating into the surrounding tissue, but dermatologists know that there are other lesions, such as granuloma pyogenicum and dermatofibromas, which appear to be infiltrative and yet do not have the neoplastic property of a true malignant condition I should say that these are capillary angiomas rather than angiosarcomas

Pityriasis Rosea? Neurofibromatosis Presented by DR EVAN B HUME

DISCUSSION

DR EVAN B HUME Why is neurofibromatosis aggravated by pregnancy?

DR BERTRAM SHAFFER Many conditions either develop or become aggravated during pregnancy Cutaneous tags, various pigmentations, verruca senilis and von Recklinghausen's disease belong to this group of eruptions

DR SIGMUND S GREENBAUM I offer the diagnosis of a mixed type of anetoderma None of the lesions look like pityriasis rosea The larger lesions resemble Schweninger-Buzzi disease

DR REUBEN FRIEDMAN I agree with the diagnosis of pityriasis rosea and von Recklinghausen's disease Dr Cipollaro of New York is opposed to biopsies in frank cases of neurofibromatosis, stating that in 13 per cent of the cases sarcoma develops at the site of the biopsy

Lupus Erythematosus, Scleroderma (Sclerodactylia), Raynaud's Disease, Sarcoidosis (Boeck's?) Presented by DR LEWIS M JOHNSON, Lancaster, Pa

Keratoses of the Palms and Soles (Chronic) (Caused by Arsenic?), Pigmentation (Generalized) (Caused by Arsenic?), Dermatitis (Atopic) of the Hands, Forearms, Ankles and Popliteal Areas (Chronic), Cirrhosis (Portal) of the Liver (Chronic) (Cause Undetermined) Presented by DR LESLIE NICHOLAS and (by invitation) CAPTAIN A FRISKEL

Examination disclosed numerous pea-sized and larger round, firm nodules, pink to brownish, distributed over the soles and toes of both feet Some of the lesions, of a verrucous nature, have dropped out, leaving a pea-sized excavation

Results of laboratory examinations, including a complete blood cell count, differential count, urinalysis, serologic test for syphilis and roentgenogram of the chest, were all within normal limits A roentgenogram of the feet showed some disuse atrophy but no bone destruction A culture from the lesions of the feet disclosed gram-positive diplococci but no fungi Histologic examination disclosed a sarcomatous stage of multiple hemorrhagic pigmented sarcoma (Kaposi)

In addition to topical therapy, the patient received potassium iodide orally, and between Feb 11 and 19, 1947, he received seven roentgen treatments to the lateral surfaces of each foot (200 kilovolts, 50 cm distance, 4 mm of copper filter) for a total of 1,050 r to each area There was considerable improvement following radiation therapy

DISCUSSION

DR ARTHUR JAMES I saw this man seven years ago His feet were swollen and had draining sinuses Biopsy showed blastomycosis He improved very much with potassium iodide therapy

DR FELIX PINKUS Today I made a clinical diagnosis of Kaposi sarcoma, and the histologic picture seems to confirm this

DR HOWARD PARKHURST The lesions now look like the idiopathic sarcoma of Kaposi, but eight months ago the condition resembled mycetoma The sinuses which were present then cleared up with moist packs of potassium permanganate solution More recently, after roentgen treatment, the nodules have subsided

DR THOMAS MILLER I agree with the diagnosis of Kaposi sarcoma The most plausible explanation would seem to be that it has recently developed on the background of an older, infectious process

DR HENRY A BRUNSTING I believe that the clinical and histologic picture is consistent with the diagnosis of Kaposi sarcoma There has been considerable improvement in the clinical picture in the month since radiation therapy was administered

Porokeratosis (Mibelli) of the Thumb of a 7 Year Old Girl Presented by DR H J PARKHURST and DR HENRY A BRUNSTING

Bright Red Nodular Tertiary Syphilid on the Thigh, Duration Eight Years Presented by DR HENRY A BRUNSTING

Tuberculosis of the Skin. Presented by DR H A. LUSCOMB for DR FRANK C KNOWLES

T C a Negro woman aged 21 years, presents a generalized, lichenoid, umbilicated, papular eruption with condylomata lata on the external genitalia The patient was admitted to the clinic in January 1947, with a history of an eruption of two months' duration

The Wassermann and Kahn reactions of the blood were strongly positive A blood cell count and the results of urinalysis were normal The serum calcium was 11 2 Roentgenograms showed the chest, hands and feet normal The result of a tuberculin test performed on April 1 with purified protein derivative (first and second test dilutions) was negative

The diagnosis from biopsy was tuberculosis

Antisyphilitic treatment with oxophenarsine hydrochloride was begun on Jan 17, 1947 The condylomata disappeared, but the rest of the eruption remained the same after three months' treatment Calciferol (vitamin D_2) therapy, 100,000 units daily, was started on May 31 and continued to the present time The eruption on the face had disappeared in six weeks The rest of the eruption has slowly improved

DISCUSSION

DR D M SIDLICK Only the microscopic evidence is in favor of tuberculosis of the skin, and I do not believe that one can make a diagnosis merely on the basis of the histologic picture The clinical evidence favors syphilis, and this is a macular atrophy following secondary syphilis

DR FRED D WEIDMAN This might be a case of sarcoid in the form that occurs in the American Negro, which responds to vitamin D_2 therapy The sections suggest sarcoid, although there are many lymphocytes, there are no giant cells The patient is anergic, but the other lesions, such as the bone changes, appear not to be present The disease is, however, in an early stage, and I think that the case should be watched because it may be one of sarcoid of the American Negro, which Dr Michelson thinks might be different from sarcoid of Boeck

DR C C THOMAS I have seen at least three examples of what appeared to be papular secondary syphilis which on further examination and failure to respond to antisyphilitic therapy turned out to be sarcoid I suggest a lymph node biopsy

Purpura Annularis Telangiectodes (?) Improved Following Treatment with Rutin and Ascorbic Acid Presented by DR SIGMUND S GREENBAUM

Follow-Up Report Presented by DR J M SCHILDKRAUT, Trenton, Pa

Some time ago I reported an extensive case of plantar warts—one of the worst I had ever seen The boy had an extensive case of fused warts on the whole anterior part of the foot and scattered warts on the heel and toes, he also had warts on his hands He had received roentgen rays, bismuth preparations and other medicaments without effect I gave him a course of bismuth injections and advised that he soak his foot, at the suggestion of Dr Livingood, in 3 per cent formaldehyde, and the condition cleared up

News and Comment

GENERAL NEWS

Third Annual Clinical Session of the American Medical Association — The Third Annual Clinical Session of the American Medical Association will be held in Washington, D C, December 6 to 9

The Clinical Session will provide a full scale scientific program specifically designed for the general practitioner Outstanding physicians will discuss such subjects as diabetes, pediatrics, laboratory diagnosis, physical medicine and rehabilitation, arthritis, dermatology, diagnosis by means of the roentgen rays, cancer and poliomyelitis Coordinated with this outstanding scientific program will be approximately one hundred scientific exhibits which will present original work on the subjects discussed

The newest offerings of one hundred and twenty-five manufacturing firms will comprise the Technical Exhibition Here will be found the latest developments in scientific medical research, drugs and equipment

Televised surgical and clinical procedures, similar to those shown in color at the Annual Session of the American Medical Association in Atlantic City last June, will be presented at the Washington meeting The demonstrations will originate in the Johns Hopkins Hospital and will be shown on screens in the Armory The television schedule will be spread over four days

The House of Delegates will meet at the Hotel Statler during this session One of the first orders of business will be the annual selection of the general practitioner who has made an exceptional contribution of service to his community

An entertainment program for attending physicians and their wives is planned The highlight of this program will occur on Wednesday evening, December 7, when Philip Morris will originate its "This Is Your Life" broadcast from the Hotel Statler The radio program will be followed by a stage show, in which outstanding stars will participate

Blanks for hotel reservations and advance registrations may be found in *The Journal of the American Medical Association*

A Case for Diagnosis (Psychosomatic Dermatitis? Dermatitis Herpetiformis?) Presented by DR REUBEN FRIEDMAN and (by invitation) DR CONRAD STRITZLER and DR JOHN B ROXBY JR

Xanthoma Eruptivum Secondary to Lipid Nephrosis Presented by DR REUBEN FRIEDMAN and (by invitation) DR WALDO E NELSON, DR CONRAD STRITZLER and DR JOHN B ROXBY JR

Combined Simple and Cavernous Angioma Presented by DR MEYER L NIEDELMAN

D A, a white girl aged 2 months, presents over the entire left side of the face an angioma cavernosum It is bright red, and the prominence of the swelling lies over the parotid gland There are numerous both raised and flat simple hemangiomas scattered over the right side of the face and neck On the lower lip there is a similar lesion

A small red area developed in front of the left ear at 2 weeks of age Another lesion formed on the lower lip, then gradually new areas developed over the left and right sides of the face and neck The patient was seen two days ago, and arrangements are being made to treat the lesions with radium

DISCUSSION

CAPT R L GILMAN, U S N This patient should be treated with sclerosing injections or solid carbon dioxide I would not use radium or roentgen rays

DR MEYER L NIEDELMAN I am afraid to use sclerosing solutions about the scalp and face because of possible thrombosis of a cerebral vessel At a meeting of the American Academy of Dermatology and Syphilology a few years ago a case was reported in which death of an infant was due to the injection of a sclerosing solution for an angioma of the face I believe the cosmetic result would be poor with solid carbon dioxide, and this substance is ineffective in the cavernous type I shall use radium, and I am sure a regression of the angioma will take place

DR H E TWINING The more rapid the growth, the greater the response one gets from radium or roentgen rays

DR M H SAMITZ I suggest that a roentgenogram be taken of the face to see whether there is any involvement of bone

DR THOMAS BUTTERWORTH, Reading, Pa Frequently extensive hemangiomas occurring in the trigeminal area are accompanied with hemangiomas of the cerebral cortex, and in treating them with roentgen rays one exposes oneself to a medicolegal proceeding If cerebral lesions develop later, the patient's parents may ascribe them to the treatment given earlier At the age of 12 or 14 the angioma on the cortex of the brain may become calcified and can be demonstrated by roentgenogram

DR HERMAN BEERMAN What is "simple" angioma?

DR MEYER L NIEDELMAN There are two types present in this infant the small, flat type, which is simple, and the elevated, doughy, vascular type, which is cavernous

Book Reviews

Malattie cutanee e veneree ed alterazioni oculari By G Sala and P Noto, with prefaces by A Grosti and B Alajmo Pp 410 Palermo, Italy S F Flaccovio, 1948

This book, which is probably the most comprehensive monograph on the subject, is the combined work of the ophthalmologist, G Sala, and the dermatologist, P Noto, both of the University of Palermo, Italy The authors discuss, in parallel articles, the embryology of the skin and of the eye and all dermatoses and venereal diseases which may affect the eye and the lids The book contains a vast amount of factual, mostly clinical and often original, material in connection with a rather large bibliography

There are some shortcomings which should be corrected in a new edition There are no illustrations and no alphabetic index, and the paper is poor, probably because of postwar difficulties It would be to the advantage of the book if the authors would agree on more rigid editing It seems out of proportion to write a page or more on the dermatologic aspects of lichen planus and other dermatoses and then to mention, in a few lines, the rarity of participation of the eyelids The spelling of foreign names and titles of publications, especially in the German references, is poor Of greater importance than errors of this kind is the omission of discussion of the work of Brunsting and Sheard and others on the high threshold level of dark adaptation in pityriasis rubra pilaris However, these shortcomings should not distract from the great value of the work as a modern reference book

Of interest is the observation of the relative frequency of dermatogenous cataract in cases of generalized psoriasis In this connection, it may be mentioned that the authors estimate that cataract develops in 10 per cent of the patients with neurodermatitis (atopic dermatitis) This percentage appears to be a higher one than is observed in America, and the discussion should prompt a study of the eye in a large number of American cases

An Introduction to Dermatology By J H Percival, M D Eleventh edition Price, $9 Pp 349 Baltimore Williams and Wilkins Company, 1947

In general this is an excellent, small, yet complete book, in which the author well meets the difficult problem of attempting to cover a large and complex field briefly The material is well organized and clearly presented and indicates logical thinking throughout There are sufficient good colored illustrations to help the presentation greatly

Though brevity and a superficial approach are necessary in a book of this type, there seems to be an insufficient attempt made to link dermatology to the whole of medicine Mention of the more serious general involvement of the body of many dermatoses is omitted in the discussion of some conditions and but briefly touched on in others

American readers, although likely agreeing in general with the material presented, will undoubtedly have varying opinions regarding certain specific ideas expressed Among such controversial points, the following ones might be mentioned that the Senear-Usher syndrome is a type of generalized lupus erythematosus and that this syndrome is identical with pemphigus foliaceus, that dermatitis herpetiformis "may imperceptibly change its character to that of pemphigus," that twelve hours is sufficient time for patch testing and that "if there is no reaction, any suspicion of the substance used for the test may be dismissed"

so far are unknown to us Treatment with penicillin and sulfonamide drugs have had little effect on the course of the disease

The nodes have a tendency to mat together The ulcers are variable in size and shape, from 2 to 5 cm in diameter, and have a soft undermining edge and irregular granulating bases, well vascularized Some of the ulcers have appeared over regions where large lymph nodes are not usually present On the roentgenogram of the skull there is an irregular, oval dehiscence of the right parietal bone under one of the tender swellings The spleen is palpable The liver is felt at the costal margin

The axillary lymph node, seen on Jan 30, 1947, was a large moderately firm node of a peculiar red-brown The microscopic sections showed a very extensive obliteration of the normal architecture, although small remnants of cortical follicles and cords filled with lymphocytes remain These are widely separated and are missing from some parts of the node Instead one finds sheets of large acidophilic or pale nonfoamy macrophages, which seem to have filled in the sinuses as well as the parenchyma Scattered in great abundance between them are eosinophils and smaller dark cells which are presumably lymphocytes In some regions the cells with dark nuclei look more like normoblasts The histiocytes or macrophages frequently have lobulated nuclei, and sometimes they contain two or more discrete nuclei Neither in their cytoplasm nor in their nuclear form do they resemble Reed-Sternberg cells They do not possess distinct nuclei as shown in Mallory connective tissue stain, there is great fibrous thickening of the capsule and decided fibrosis of some of the cell-filled lymphatic sinuses Fibrous tissue is especially dense around the blood vessels of hilar portion of the node Evident in Mallory stain more clearly than in hematoxylin and eosin is the presence of clefts or small vacuoles of the cytoplasm of the large macrophages However, the appearance is quite different from that seen in the large cells of Gaucher's disease, in Niemann-Pick's disease or in Hand-Schüller-Christian's xanthomatosis Stains for gram-positive and acid-fast bacteria were entirely negative Sudan stain reveals an occasional macrophage containing recognizable septums A very small amount of this lipid is antisotrophic

The scraping of the sinus tract consists of multiple bits of granulation tissue and fragments of skin which show changes similar to those of the lymph nodes In the section of the skin the eosinophils are less prominent Plasma cells and large mononuclear cells are present The disease has been diagnosed once as tuberculosis by smear examination, and at another time as Hodgkin's disease by lymph node examination

In our laboratory tests, culture of the exudate on blood agar and Sabouraud's medium showed Staphylococcus albus The acid-fast stain was repeatedly negative Blood culture was negative White rat and guinea pig inoculations were repeatedly negative, results of the tuberculin patch test, blastomycin test, histoplasmin skin tests and purified protein derivative tests were all negative The Kahn reaction of the blood was negative Sternal puncture showed the myeloblast-erythroblast ratio to be elevated Other observations were sedimentation rate 41 mm in 1 hour, leukocytes 12,000, hemoglobin 12 Gm, erythrocytes 4,400,000, poloymorphonuclear cells 72 per cent, lymphocytes 26 per cent, eosinophils 2 per cent, hematocrit 41 and blood lipids 787

The histologic section from a lymph node presented a very unusual appearance which did not resemble any lymph node previously studied in our laboratories Certainly tuberculosis and Hodgkin's disease in their usual forms can be excluded On anatomic evidence at present, we have no clue as to whether this peculiar

granulomatous condition is an infection or is caused by a metabolic anomaly It more closely resembles the tissue reaction seen in eosinophilic granuloma of bone than any other condition known to us

DISCUSSION

DR CARL W LAYMON, Minneapolis There is not a great deal known about eosinophilic granuloma of the skin, since not more than a dozen cases have been reported and in those cases the diagnosis was doubtful The disease has been reported in nodules or plaques which brings up the interesting question as to whether cutaneous eosinophilic granuloma is related to eosinophilic granuloma in the lung and other organs That brings up a possible relation to Christian's disease I believe that all of these diseases are part of the same toxic process and that this occurs as a fatal type and the Christian type occurs as a more benign disease Cutaneous eosinophilic granuloma and eosinophilic granuloma of the bone are part of the same process Last April, at the meeting in Detroit, Dr Curtis showed a patient with eosinophilic granuloma of the bone with cutaneous lesions

DR A C CURTIS, Ann Arbor Experience in 1 case does not make one an authority The patient that Dr Laymon mentioned had plaquelike lesions on the vulva and one lesion on the scalp, with a destructive process in the bone of the mastoid and in the crest of the ilium The lesions were plaquelike and very red Our attention was called to them because of the redness They promptly disappeared with a minimal amount of low voltage roentgen rays, as did the destructive lesions in the bone As I looked through the records to see whether any studies had been made, it occurred to me that this might be a disseminated sporotrichosis

DR STEPHEN ROTHMAN The diagnosis of eosinophilic granuloma was first suggested by our pathologist, Dr E M Humphreys I realize that these cutaneous lesions have not been reported in the literature It does not agree with any description published in the literature It reminded me of Niemann-Pick's disease, but the pathologist said that it was not Clinically it was typical scrofuloderma Extensive examinations were made for fungi The patient was seen in several departments I think that we can by now exclude tuberculosis and mycosis

Cosmetic Repair (Surgical) of Lupus Erythematosus Hypertrophicus et Profundus. Presented by DR SAMUEL M PECK

E B, a housewife aged 40, is presented from Mount Sinai Hospital, New York, with an eruption which appeared after exposure to sun and which has been present since 1925 The patient has been under observation since 1926 She has received a great deal of therapy, including treatment with gold and bismuth preparations, cobra venom and other remedies, but finally improved with administration of suramin sodium (naphuride sodium®) Subcutaneous infiltrations appeared in 1938 With improvement, the infiltrations disappeared, leaving atrophic areas resulting in cosmetic defects

There are still a few areas of activity on the face and scalp consisting of circumscribed patches of atrophy and telangiectasia The sites of the defects have been filled in by means of skin grafts

The patient has been kept practically free of lesions by injections of naphuride® The dosage was 100 mg with increase at each injection until a maximum dosage of 300 mg was given All injections were intramuscular and given once a week From October 1945 until the present she has received several courses of this drug the first consisting of eleven injections and the second of eight The third course, which comprised seven injections, was begun in June 1946

The reason for presenting the case was the great loss of subcutaneous fat at the sites of the previous infiltrations, with scarring over the flush areas of the cheeks A repair, consisting of dermal grafts, was performed by Dr Michael L Lewin Only the dermal component of the graft was utilized in order to limit shrinkage as much as possible

DISCUSSION

DR FRANCIS P MCCARTHY, Boston May I ask Dr Peck whether, on the basis of its use in 40 cases, he feels that this drug is safe for use by the medical profession? It seems to me that it is a toxic drug, capable of producing a renal irritation, as evidenced by casts and albuminuria Personally, I would prefer to use a less dangerous remedy

DR MAURICE J COSTELLO I have used naphuride® in the treatment of lupus erythematosus in 6 cases, with spectacularly good results in 3 of them, in half of the patients severe toxic reactions developed and the use of the drug had to be discontinued One patient had disturbance of vision, 2 had swelling of the hands and feet accompanied with intense pruritus, others had pain and swelling of the

Dark field examinations of the lesions on the tongue and arm gave negative results, as did the Mazzini reaction of the blood A complete blood count, examination of the urine and roentgenograms of the lungs revealed no abnormalities

Biopsy of the lesion on the arm, done at Bellevue Hospital, showed a nonspecific granuloma with epithelioid cells, plasma cells and lymphocytes

Material from the lesion on the left side of the dorsum of the tongue was examined by Dr Fred D Weidman, who reported the lesion to be syphilis or oriental sore He found the epidermis to be enormously acanthotic and parakeratotic Although its squamous cells were greatly swollen, there was no evidence of neoplastic activity, even at the basement membrane There the basal cells had undergone metaplasia into squamous forms There, too, many of the inflammatory infiltrative cells of the corium were infiltrating the epidermis A rather heavy infiltration of inflammatory round cells lay immediately below the epidermis It crowded the papillae but did not extend farther than the subpapillary plexus of vessels The cells were distributed diffusely, and although lymphocytes were dominant, there was a large intermixture of elongated nuclei which were interpreted as epithelioids However, none of them was congregated into individual foci in such a way as to constitute miliary granulomas There were numerous other elongated nuclei which were clearly those of histiocytes, but they were readily distinguishable from the plumper epithelioid ones

The significant features in the diagnosis resided in the epithelioid cells Such cells do appear in the lesions of oriental sore, but in the absence of the specific organisms the epithelioids could reasonably be those of syphilis or tuberculosis, the diffuse distribution would point more toward syphilis The protozoa were not recognizable in these sections

DISCUSSION

Dr Fred Weidman, Philadelphia The solitary item of significance in the histologic picture is the presence of epithelioid cells, which are not gathered into foci to indicate definite miliary granulomas of either syphilis or tuberculosis In other words, it is a diffuse reaction such as occurs in pneumonia alba In such a situation it is necessary to resort to methods for the identification of the parasite itself I might say that the only time recently that I have seen the Leishman-Donovan body in sections was at Dr Lloyd W Ketron's laboratory, but that is unusual A much more preferable method of demonstrating the parasites is by means of smears, so I should say that if the pursuit of the Leishman-Donovan body is to be continued, that is the method of choice After seeing the patient today, I do not think the lesion could be that of leishmaniasis, as the infiltration of the tongue is not particularly heavy It is rather superficial for that disease, and leishmaniasis is usually more suppurative, as I recall it, there is no evidence of pus in the sections After seeing the patient again, I do not think it is likely to be syphilis, which I intimated in the histologic reports I was swayed by the fact that the infiltration is diffuse

Dr Clarence S Livingood, Philadelphia Several years ago I had an opportunity to observe a rather large number of patients with cutaneous leishmaniasis, and this case certainly does not correspond with any of those which I have seen I gathered that the type of ulcer which the patient had was not characteristic of that disease According to the information which I obtained from him, his stay abroad was entirely confined to Greece, and as far as I know leishmaniasis does not occur in that country

Dr Bernard Appel, Lynn, Mass The lesions on the lips and in the mouth are, in my opinion, consistent with lupus erythematosus It is not unusual, in my experience, to find lesions on the lips which in the early stages resemble those of

joints and in 1 the urine indicated renal irritation I believe that the drug is to be used with great caution It is effective, but it should be given only in the refractory, severe cases

DR. GEORGE C ANDREWS I agree with Dr Costello I think Dr Peck has had more experience with germanin in the treatment of lupus erythematosus than anybody in this city, and he can do things with it, perhaps, that the average physician cannot do I agree fully with his remarks, except that I think he should be a little more careful in explaining how toxic naphuride® is Severe anemia, hepatitis and nephritis occur from its use The total dose must be kept under 1 Gm for a long period I feel, as Dr Costello does, that it is an extremely toxic drug I no longer use it in cases of pemphigus, although I do use it for lupus erythematosus of the discoid type in small doses of 100 mg once a week for six or eight weeks If the patient is carefully watched, such doses are fairly safe In some cases fine results are obtained, and in others it does no good

A Case for Diagnosis (Lymphoblastoma? Pemphigus? Dermatitis Herpetiformis?) Presented by DR. ISADORE ROSEN

E A, a woman aged 70, had an eruption of four years' duration This began as vesicular plaques on the wrists and hands After roentgen ray treatment the eruption disappeared, but it soon recurred on the face, chest and extremities Since then there have been complete remissions and also exacerbations of varying degree, the patient having to be hospitalized on several occasions

The eruption during the past few years has been generalized and has consisted of grouped and fused lesions of vesicular character On the face and extremities infiltration has been frequently observed, and at times the lesions have been oozing or covered with scales At other times they have been annular, with central vesicular crusting, and have closely resembled pityriasis rosea In August 1946, shortly before her hospitalization, almost the entire surface of the skin was involved, except for the palms and soles At that time the patient presented on the face, neck and chest diffuse dull erythema, edema and exfoliation The rest of the body showed rounded erythematous lesions from 2 to 7 cm in diameter, with a scaly collar just inside the erythematous border In some areas there were flattened bullae containing clear fluid During the patient's stay in the hospital new bullae appeared from time to time

The Wassermann and Kahn reactions of the blood were negative Frequent blood counts showed leukocytosis, with a count which at times reached a figure of about 18,000, and a high eosinophil count, on some occasions as much as 27 per cent Roentgenograms of the lungs revealed moderate central thickening of the lymphomatous type, with clear peripheral lung fields A roentgenogram of the spine showed localized hypertrophic changes of the lower cervical area.

Patch tests with 30 per cent potassium iodide and potassium bromide ointment gave a strongly positive reaction Chemical studies of the blood, including determination of the nonprotein nitrogen, total protein, albumin, globulin, icterus index, calcium, inorganic phosphate and sugar, showed normal figures The last examination of the erythrocyte sedimentation rate during an exacerbation showed 93 mm per hour The basal metabolic rate was within normal limits

Four biopsies taken at different times were reported to show (1) chronic dermatitis, (2) neurodermatitic reaction, (3) psoriasiform dermatitis, and (4) pemphigus The description of the last slide was as follows "There is an

lichen planus clinically because of the white reticulation and their limitation to the vermillion of the lip With the progress of the disease, however, the lesions become more characteristic as they extend to the glabrous skin I anticipate that that is what will happen in this case Furthermore, I have not found that lichen planus produces such extensive and persistent ulceration of the tongue when it does occur there, that is to say, this picture is more consistent with lupus erythematosus If it actually is lupus erythematosus, it is also my opinion that it is likely to be extremely resistant to treatment and that the prognosis should be guarded

DR FRANCIS P MCCARTHY, Boston Dr Weidman, does the lesion on the tongue show epithelioid tissue?

DR FRED WEIDMAN, Philadelphia Yes

DR FRANCIS P MCCARTHY Do we get this reaction in lupus erythematosus?

DR FRED WEIDMAN No

DR MAURICE J COSTELLO The question of tuberculosis of the tongue also came up, but roentgenograms showed the chest to be normal We have seen patients who had both lichen planus and lupus erythematosus simultaneously I think the lesions on the lower lip suggest lichen planus and am inclined to agree that the lesion on the tongue is lupus erythematosus or lichen planus clinically

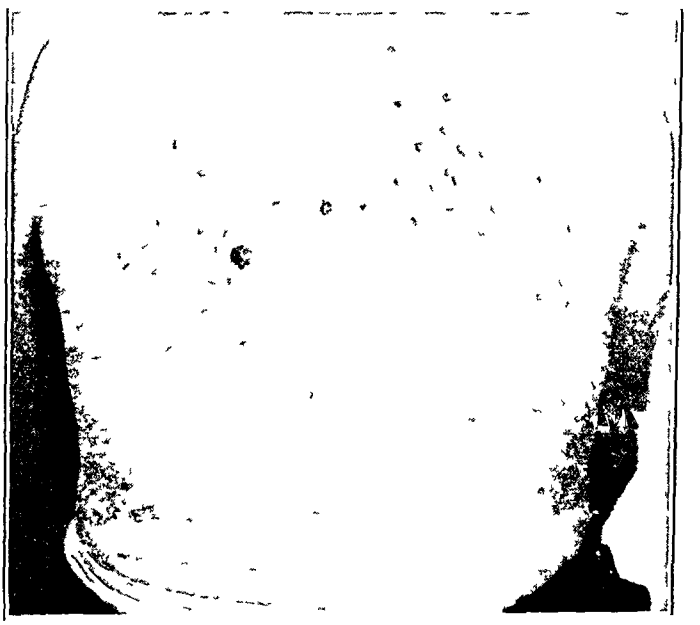

Fig 7—Lesions of leiomyoma

Leiomyoma Presented by DR ANTHONY C CIPOLLARO

P P, a man aged 52, is presented from the Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital, with an eruption of fifteen years' duration which has not changed essentially in the past twelve years

In the scapular region there is a symmetric eruption of slightly reddish, mostly oval, elongated and spherical infiltrated, firm, nodular lesions which are arranged in the lines of cleavage There is a moderate number of similar but smaller and less indurated lesions in the lower lumbar and gluteal region Some of the lesions are tender to pressure The patient complains of severe pain in the region of the eruption during cold weather

intraepidermal cavity with numerous eosinophils In the upper cutis the vessels are dilated and show swelling of the intima There is a diffuse infiltration of small round cells, wandering connective tissue cells, numerous eosinophils and occasional plasma cells"

Treatment has consisted of superficial irradiation, injections of arsenic and liver extract and blood and plasma transfusions Sulfapyridine was given, but its use had to be discontinued because of nausea and vomiting The last treatment given in the hospital and being continued in the clinic is administration of

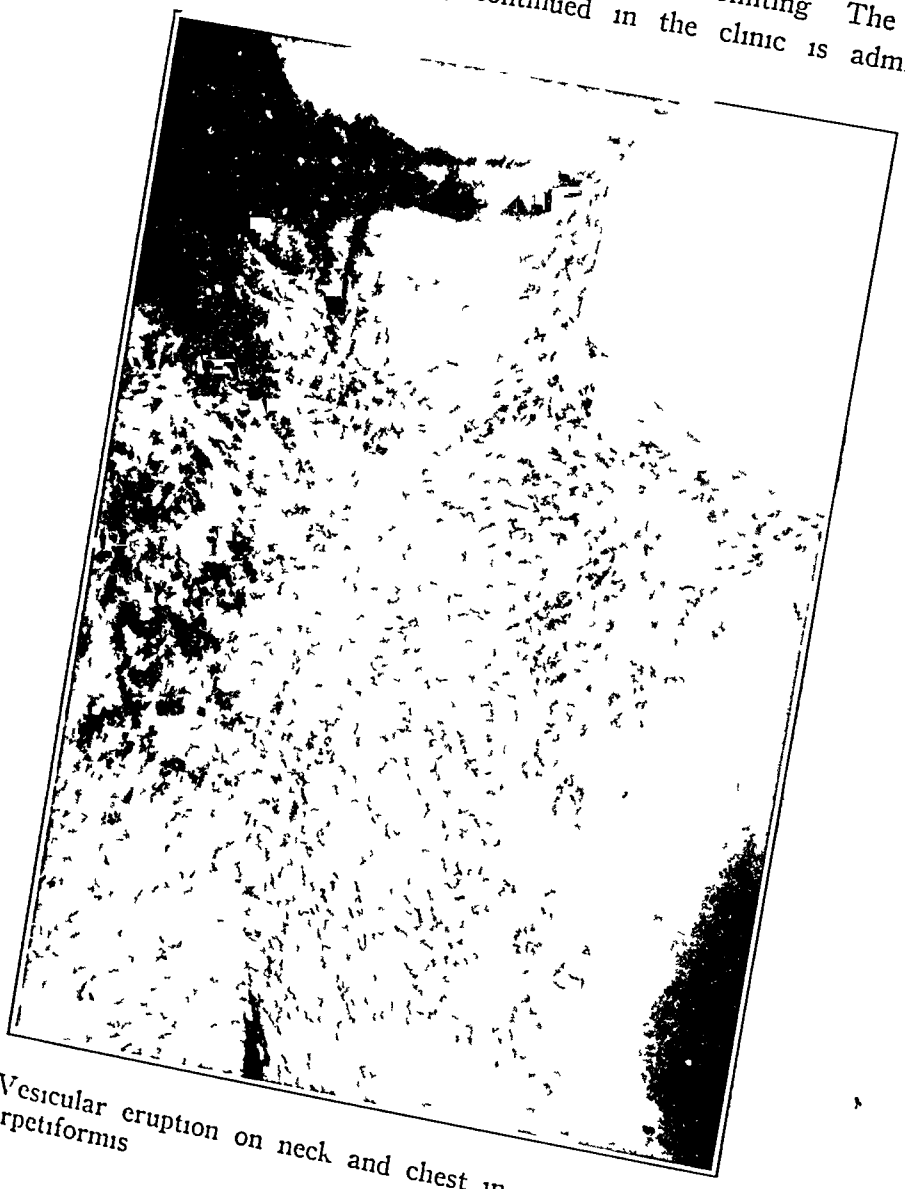

Fig 1—Vesicular eruption on neck and chest in a woman with questionable dermatitis herpetiformis

mphuride® in a dose of 0 25 Gm intramuscularly twice a week This seems to have benefited the patient

DISCUSSION

DR FRANCIS A ELLIS, Baltimore Nausea is not a contraindication to the administration of sulfapyridine We have had severe cases in which we continued to use the drug in spite of nausea and vomiting, and even though the dosage was decreased, good results were obtained in three or four weeks

Fig 8—Photomicrograph showing leiomyomatous changes

: WILBERT SACHS This patient has had long-standing dermatosis, and
:rimposed pemphigus developed I believe that the underlying dermatosis is
nct dermatologic entity that has never before been described I have now
bout 6 such cases, and the microscopic picture is always the same There
eurodermatitic reaction, with a focal cellular infiltration of plasma cells
rocess suggests an exudative discoid and lichenoid dermatosis on the one
nd a mycosis fungoides on the other Yet it is neither of these diseases but
ite entity falling somewhere between both Clinically these patients may
nacules, papules, nodules or patches This patient also has pemphigus,
ly due to a toxic reaction

WALTER F LEVER, Boston The cutaneous lesions are eczematous in
It is possible that the disease will turn out to be mycosis fungoides
ntly in the prefungoid state of mycosis fungoides it is impossible to find
histologic sections atypical cells which would establish the diagnosis of
; fungoides Instead, only banal inflammatory changes are present In
to a diagnosis of pemphigus, I think that is a disease entity and does not
as a toxic reaction secondary to another dermatosis I would not dare
.e a diagnosis of pemphigus on histologic grounds alone, except in some
of pemphigus vegetans Bullae may occur as an unspecific reaction, both
matous cutaneous disorders and in mycosis fungoides

WILBERT SACHS I did not intend to imply that this was a case of mycosis
les In fact, I believe that disease will never develop in the patient This
the proper time to discuss the differentiation between dermatitis herpeti-
and pemphigus I am not convinced that we know what pemphigus is,
the lesions of that disease are toxic bullous manifestations There are
characteristics on which a diagnosis of pemphigus can be made micro-
lly

GERALD F MACHACEK We have had similar problems at the Presby-
Hospital in which the diagnosis was uncertain The lesions were pemphigoid
e thought to be those of Duhring's disease, and treatment with sulfapyridine
ied and found wanting One such case was presented before the New
Academy of Medicine last Tuesday Dr Vero found that the lesions in
ise and in another disappeared with large doses of vitamin A Perhaps
)sen has already tried that form of therapy

ISADORE ROSEN This patient has been under observation for more than
ears The only subjective symptom has been intense itching, and her
physical condition has never been impaired I am of the opinion that this
eruption is probably due to the effects of treatment over many months

oderma Vasculare Atrophicans with the Histologic Picture of ycosis Fungoides Presented by DR DAVID BLOOM

itis Factitia Dystrophy of the Nails and Keloids of the Palms d Soles Presented by DR GEORGE C ANDREWS

C F, a widow aged 66 from the Roosevelt Hospital, has arteriosclerotic disease, diverticulosis of the colon and hypertrophic arthritis Her psychi-tatus has not yet been determined

Routine examination of the blood and urine gave normal results

Biopsy of a nodular lesion was reported previously to show neuroma Recently another biopsy was reported as showing leiomyoma

Unfiltered roentgen irradiation seems to have alleviated the pain of which the patient has complained

DISCUSSION

DR WILBERT SACHS I made both diagnoses I feel that in regard to multiple small lesions for which the diagnoses of both neuroma and leiomyoma are suggested it is possible that it is not a single, distinct type of tumor but a combination of both Of course it is often difficult to differentiate between neuroma and leiomyoma In this case we did some special stains on the first section and these showed a neuroma On the second section it was not necessary to do any special stains since there was a classic picture of leiomyoma

Pityriasis Rubra Pilaris Uninfluenced by Treatment with Vitamin A Presented by DR E W ABRAMOWITZ

Ragweed Dermatitis Presented by DR MAX SCHEER

P B, a man aged 65, is presented from the Skin and Cancer Unit of the New York Post-Graduate Medical School and Hospital He loads Pepsi-Cola bottles as an occupation He was in good health and free from any cutaneous disease until September 1936, when he walked through some lots in Astoria, N Y, without stockings A vesicular eruption appeared on the dorsa of the feet and legs which was at first called eruption from poison ivy and which lasted five months It recurred in September 1937, when it was slight on the feet and legs, mild on the face, hands and forearms and severe on the scrotum The eruption then became perennial, with exacerbations from September to May June and July are the most comfortable months for the patient

There is a thickened, lichenified eruption on the face and forearms The eruption stops rather abruptly on the upper third of his forehead, which is protected by his hat

Reactions to patch tests with oleoresins of short ragweed, cocklebur, sheep sorrel, Kentucky blue grass, red top, poison ivy, orchard grass and timothy were positive Patch tests with the protein extracts of trees, grasses and weeds showed a positive reaction only to oak Scratch tests with these protein extracts gave negative results

The histologic picture was that of a contact type of eczema

No specific treatment has been given as yet The patient has been receiving eight 50 mg tablets of tripelennamine hydrochloride (pyribenzamine®) daily, with only slight alleviation of the itching

DISCUSSION

DR JOSEPH MULLER, Worcester, Mass From the appearance I would be likely to believe that it is a ragweed dermatitis, but, on looking at the calendar and the patient, I just cannot accept that diagnosis After all, ragweed dermatitis is nothing else but a contact dermatitis, and the patient has certainly not been exposed to ragweed for a long time The fact that the reactions to patch tests were positive means nothing I think the patient has at some time had contact dermatitis If ragweed caused the trouble, it should have started in the fall and be over by now

In 1935 the patient was told that she had a fungus infection of the finger nails, which she felt was the reason for her various functional and organic disturbances Since that time she has scraped her palms, soles and finger nails daily in order to "rid her system of disease"

There is almost complete absence of the finger nails and toe nails On the palms and soles are deep, red, linear, thickened areas On the hands, these extend over the palmar surfaces of the fingers

The Kline and Mazzini reactions of the blood are negative The urine is normal, and a complete blood count shows a moderate hypochromic anemia The basal metabolic rate is —4 per cent

Moniliasis Presented by Dr George C Andrews

R V, a girl aged 9, is presented from the Vanderbilt Clinic She was normal and healthy at birth and was well until the age of 2, when "double pneumonia" developed After this she remained underweight and had recurrent furunculosis which continued until the onset of the present illness In August 1943, when the patient was first seen, there was an eruption involving the scalp, mouth, nails and skin which had appeared ten months previously The patient had been hospitalized elsewhere, without improvement

On admission in 1943 the child appeared malnourished Purulent crusted lesions were present on the scalp The mucous membranes were covered with a grayish exudate, the nails were thickened, and many poorly limited, scaling, erythematous lesions were present on the shoulders

Extensive studies have been carried out in the three and one-half year period, only the pertinent findings are presented Repeated cultures of material from the scalp, skin, nails, mouth, sputum and feces were positive for Candida albicans Roentgenograms of the gastrointestinal tract in 1945 showed disturbed function of the ileum In 1946, agglutination of the blood serum for C albicans was positive in a dilution of 1 128

Examination of tissue from the back revealed intraepidermal pustules, with a leukocytic infiltrate in the pars papillaris of the corium

Locally, various preparations, including sulfur, sodium perborate, sodium propionate and gentian violet, have been used Crude liver extract multiple vitamin preparations, Candida vaccine and antiserum were used systemically In 1945, during a nine week period of hospitalization, a protoanemonin antibiotic was administered locally and orally Since July 1946 treatment has included iodine solution locally and strong solution of iodine with folic acid by mouth Recently there has been slight improvement in the cutaneous lesions, although the scalp, mucous membranes and nails are unchanged

DISCUSSION

Dr George C Andrews I have always believed in the use of iodine for moniliasis, and this case is presented to show the effect of that drug The patient has been helped a good deal She has also been getting folic acid by mouth during the past few weeks In the *British Journal of Dermatology* there have been reported cases of tropical sprue cured with folic acid

Dr Maurice Sullivan, Baltimore I should like to suggest to Dr Andrews, in case the eruption does not respond to iodine, the use of sodium caprylate, which has been reported to cure moniliasis when other fungicides fail

DR JOSEPH GOODMAN, Framingham, Mass In cases of ragweed dermatitis, which lasts around the year, it must be remembered that there is often a cross sensitization between ragweed and Pyrethrum I note that other tests were done in this case, but I see no reference to Pyrethrum It would be possible for the patient to be exposed to Pyrethrum the year round That should be considered as a possibility

DR BERNARD APPEL, Lynn, Mass I should like to confirm the observations made by the last speaker and also to point out the fact that many patients subject to ragweed dermatitis are those who live in the country and work around barns where sprays against flies and insects are used, and of course we know that they contain Pyrethrum and products of that family In my opinion it is important to do patch testing with these substances, as well as with the solvents used in insecticides

DR DONALD S MITCHELL, Montreal This man has never been hospitalized I wonder whether it would help to admit him and remove ordinary contacts such as clothing and soaps

DR JACK WOLF The eruption on the torso as seen today is incidental, it developed after a recent cold and may be the result of medication which he received It has no relation to the other eruption This man has been tested with other oleoresins as well as ragweed fractions We have had a number of cases of ragweed dermatitis in which persistent eruptions developed and remained throughout the entire year after several seasonal attacks This persistence may be due to the development of sensitization to other allergens which act at the same site

Lymphoblastoma Mycosis Fungoides with Eczematous Lichenoid and Granulomatous Lesions Presented by DR A BENSON CANNON

Dyskeratosis Congenita with Pigmentation, Dystrophia Unguium and Leukoplakia Oris. Presented by DR FRED WISE

Circinate Sarcoid Presented by DR EUGENE F TRAUB

A Case for Diagnosis (Erythroderma Ichthyosiforme Congenitum? Erythroderma Exfoliative Universalis Tuberculosa?) Presented by DR A BENSON CANNON

DR J GARDNER HOPKINS I would question Dr Peck's comments regarding Candida albicans on normal skin, because some years ago Dr Rhoda Benham made careful surveys of normal skin and found other species of Candida but could not find C albicans I think if the differentiation is properly made, one may say that M albicans is rare or nonexistent on normal skin It is found in the normal intestine *I should like to testify to the improvement of this patient under Dr Andrews' treatment* We had her under our care for some time, using sodium caprylate among other things, and she was much worse than she is today

DR DUDLEY C SMITH, Charlottesville, Va In Washington a symposium on antibiotics was held recently There were reports on two substances with fungicidal properties both on local application and on internal injection One was obtained from Bacillus subtilis, although it is not the same as subtilin, and is called "eumycin" The other was developed in the Department of Agriculture last year in an attempt to find something to counteract "tomato wilt" They obtained an extract from tomato leaves which is called "tomatin" Both agents, so the reports stated, have a good therapeutic effect in vitro in various types of fungus infections—monilia, trichophyton and yeast

DR C GUY LANE, Boston It seems to me that the disease moniliasis is increasing We seem to have had more patients in our clinic recently, and I am just as much impressed with the obstinacy of the disease as I was years ago I do not believe we have made much headway in therapy We have had 3 or 4 cases lately in which there was opportunity to make fairly careful studies, and we have run the gamut of therapy We have been interested in trying the method developed at Duke University, where a person with pulmonary moniliasis recovered after serum therapy (J A M A **130** 205 [Jan 26] 1946) I wonder if anything further has been done, perhaps in the way of increasing the titer of rabbit serum by gradually increasing doses A great deal more intensive study is needed in these cases because they are potentially serious Lesions involving the mouth and larynx are obstinate and become generalized, with a fatal ending

DR JASPER L CALLAWAY, Durham, N C We also have our troubles treating moniliasis of the skin at Duke Hospital The patient whom Dr Lane mentioned had pulmonary moniliasis and was treated with a stepped-up course of antiserum and eventually recovered We have not been able to cure any patients with generalized moniliasis of the skin, regardless of the type of treatment

M A, a girl aged 17, is presented from Bellevue Hospital with a lesion of the left side of the mandible She was previously presented by Dr Maurice J

BROOKLYN DERMATOLOGICAL SOCIETY

Abraham Walzer, M D, *President*
Seymour H Silvers, M D, *Secretary*
March 17, 1947

Mycosis Fungoides in a Patient with Psoriasis Presented by Dr L M Waterhouse

J J, a man aged 46, born in the United States, first consulted me twelve years ago, at which time a diagnosis of psoriasis was made Six or seven years ago he was treated at a well known New York dermatologic clinic where the diagnosis was confirmed clinically and histologically He had received ultraviolet rays, coal tar preparations and other topical medication There was no history of his ever having received arsenic preparations Two years ago the lesions became raised and tumor like At that time a biopsy specimen from one of these lesions was reported as suggesting lymphoblastoma, but no more definite diagnosis was made The biopsy was repeated two months ago by another histopathologist, who suggested the possible diagnosis of mycosis fungoides

Results of repeated serologic tests for syphilis were negative Results of blood cell counts and urinalyses were normal

Examination shows a generalized eruption There are quarter-sized to dollar-sized flat, red, scaly patches There are a few lesions on the lower part of the back and thighs, which are raised and tumor like The face shows an ill defined erythema with scaling On the scalp are similar patches with alopecia

DISCUSSION

Dr Seymour H Silvers This is a most unusual case It seems that the diagnosis of psoriasis was established independently by different competent dermatologists This diagnosis was corroborated by histologic studies At present there are seen a sufficient number of lesions which are infiltrated and tumor-like to warrant a clinical diagnosis of granuloma fungoides However, we cannot completely ignore the findings of two able histopathologists who failed to corroborate the diagnosis of granuloma fungoides It is not unusual for the histopathologist to fail the clinician when the latter needs him most

Dr L M Fruchtbaum The picture is not that of psoriasis On the other hand, there are two large lesions and numerous smaller ones on the body and extremities which are definitely infiltrated In spite of the fact that the patient feels and looks physically well, I believe that this is a case of mycosis fungoides

Dr E A Gauvain I believe that the disease in this case was originally mycosis fungoides, as it is now I did not see any lesions typical of psoriasis on this patient, although such a diagnosis might have been considered in a few lesions had they been the only ones present I have never seen a case of undisputed psoriasis, even though followed through many recurrences, that terminated as mycosis fungoides Clinically there is now a polymorphous type of lesion, changing in character, of a dusky color, causing some itching and finally developing into nodules, which, to my mind, are typically mycosis fungoides

Dr Abraham Walzer Clinically, this is a case of mycosis fungoides The disease developed in a manner that it does in many cases It never was psoriasis, irrespective of the fact that histologically it was first reported as psoriasis

Costello at the New York Dermatological Society in January 1947 and by Dr Emanuel Muskatblit at the Section of Dermatology and Syphilology of the New York Academy of Medicine on Feb 4, 1947

DISCUSSION

DR. GEORGE M LEWIS At a recent meeting in Cleveland, Lamb, of Oklahoma City, discussed the therapy of actinomycosis and stated that it should include (1)

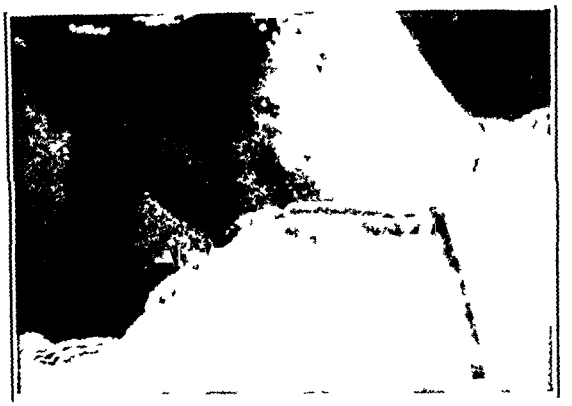

Fig 2—Periarteritis nodosa in a woman aged 35

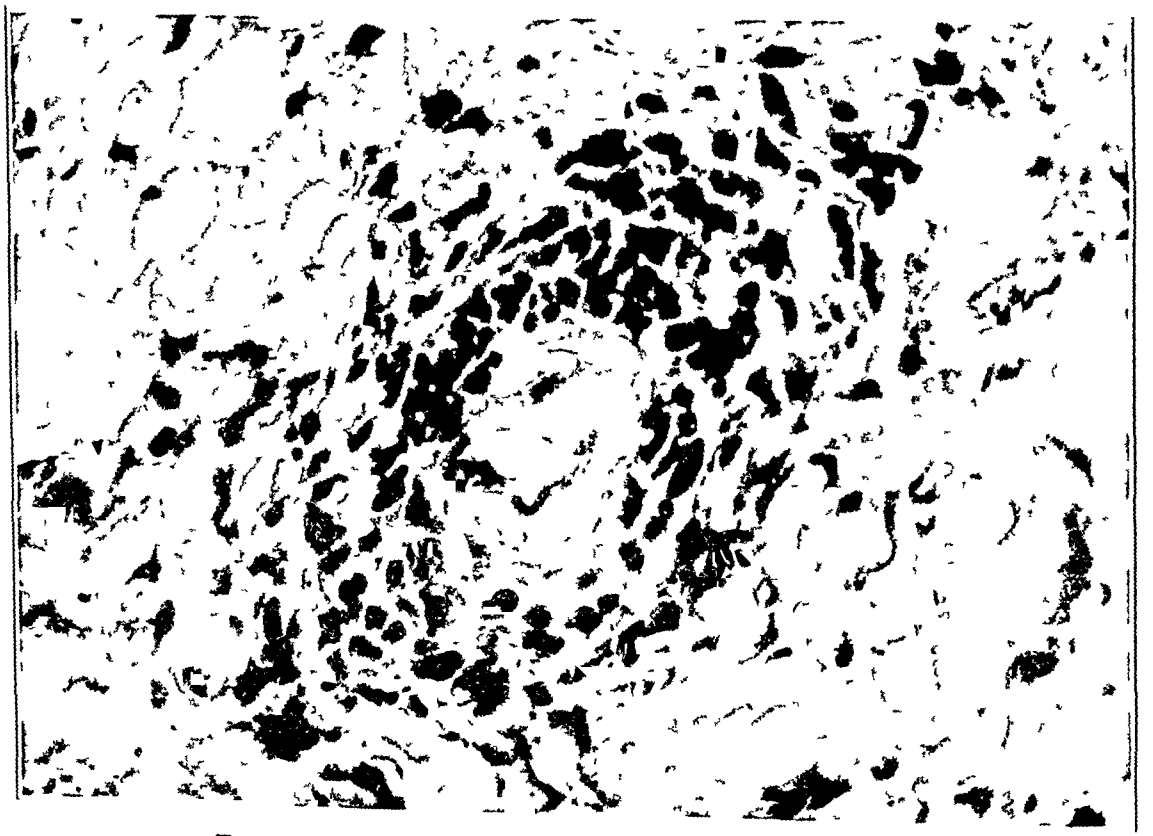

Fig 3—Photomicrograph of area of periarteritis nodosa

penicillin in large doses, which this patient has received, (2) one of the sulfonamide drugs, and (3) roentgen irradiation He favored this combination of remedies as superior to any one alone or to any other type of treatment now available

Mycosis fungoides may begin with what may appear to be psoriasis, parapsoriasis, eczema or any other condition I believe that just as the clinical picture, at the start, may be atypical, so the histologic picture may be more or less vague and indefinite At the present, this man shows lesions which, to my mind, are classic examples of mycosis fungoides

Epithelioma of Penis Presented by DR S I GREENBERG

Multiple Keloids Presented by DR MAX LERNER

J G, a girl aged 12, was seen at the Kings County Hospital Dermatologic Clinic on March 3, 1947 She had chickenpox in October 1946, and "marks" developed where there had been blisters

There are hard nodules, pea to bean size, distributed on the face, neck, abdomen and thighs Some are colorless and others yellowish white A few are erythematous with telangiectasia All the lesions are limited to the sites of the original varicella blisters There is no history of keloidal scars from previous injuries

DISCUSSION

DR ABRAHAM WALZER The keloid tendency does not have to be present during the entire life of the patient There may be periods when the tendency does not show itself My experience has been that if keloid is treated before it has been present six months, with roentgen rays, there is a chance of flattening of the lesion After six months, roentgen therapy is of no value This has been explained on the principle that connective tissue cells mature in about six months When the cell becomes fully mature, it cannot be reduced, but as it is growing and developing (that is, up to six months), its growth can be stopped No matter how much roentgen therapy is given after six months, it is of no value However, if the lesion is excised and roentgen rays given, the lesion may be suppressed

Generalized Sarcoidosis Presented by DR MAX LERNER and DR FRANK D JENNINGS JR (by invitation)

Xanthoma Tuberosum Presented by DR C T CHIARAMONTE

Xanthomatosis Juvenilis Presented by DR C T CHIARAMONTE

V S, a white girl, aged 5 years, has several discrete, bean-sized, yellowish nodules on the face and neck Her liver is enlarged to 2 fingerbreadths below the costal margin with an even, smooth edge

This child was first seen when she was 6 weeks old She showed many shiny, yellowish nodules which were generalized and of varying sizes There was a reddish halo around the lesions Some of the larger ones were oval in shape Many of the lesions showed multiple punctate depressions at the follicular orifices Lesions were also found on the mucous membranes of the mouth The lesions were noticed soon after birth

Dermatitis Factitia Actinomycosis? Presented by DR THOMAS N GRAHAM

Pachyonychia Congenita (Keratosis Palmaris et Plantaris Dystrophia Unguium and Leukoplakia Oris) Presented by DR FRED WISE

S H, a woman aged 40, and L H, her son aged 16, were previously presented before the Manhattan Dermatologic Society on January 14 by Dr Fred Wise

Both patients show hard, thick, painful, hyperkeratotic, lemon-colored growths on the soles, heels and toes The toe nails and finger nails are elongated, curved, discolored and dyskeratotic There are leukoplakic patches on the buccal mucosa

Fig 4—Dermatitis factitia in a woman of 38

and also on the tongue in the mother, who in addition presents dry, scaly, diffuse, seborrheic patches on the scalp Her basal metabolic rate was —20 per cent in February, and the son's was —14 per cent

DISCUSSION

DR FRED WISE This is the second case of the kind to be described in this country Cole and his collaborators described a case fully in the ARCHIVES, and this case is almost an exact replica of theirs The problem is one of therapy Both patients are practically crippled One lesion on the mother's knee was excised and a full thickness graft applied, and the growth recurred promptly in the area of the graft Dr Peck suggested administration of large doses of vitamin A, and this is being given, but too little time has passed to expect results I am pessimistic about any treatment whatever, except possibly an orthopedic procedure to permit the patient to walk with some degree of comfort

The infant was placed on a low fat diet and was reexamined a year later It was observed that occasionally there was a generalized flushing of the skin During the period of observation, some of the lesions appeared vesicular, the mouth lesions disappeared and the cutaneous nodules grew in size Many of the lesions showed flattening at the periphery, and a few lesions disappeared Since then all lesions have undergone involution except those on the face and neck The skin at the sites of former lesions has become brownish red There has at no time been any jaundice or pigmentary changes affecting the normal skin

A biopsy performed during infancy revealed a dense infiltrate in the cutis, consisting of epithelioid cells, the cytoplasm of which had a vacuolated appearance and simulated fat cells

DISCUSSION

DR SEYMOUR H SILVERS I followed 2 cases of xanthomatosis juvenilis for many years The patients came under my care during the first month of their lives I watched new lesions appear, and, as the children became older, the lesions gradually flattened out and finally disappeared I believe that, regardless of therapy, the lesions of xanthoma juvenilis will disappear when the child reaches the age of 6 to 7 years It is likely that xanthomatosis juvenilis should be classified with the nevi rather than with the diseases due to metabolic disturbances

DR ABRAHAM WALZER These patients should have a complete determination of the lipids of the blood Increased cholesterol does not necessarily imply that every case of xanthomatosis is due to cholesterol disturbance If any other fats are disturbed, the cholesterol may be increased in the blood To what is the yellowness of the cholesterol lesions due? Cholesterol and its esters are white, but the lesions are not The yellowness is probably due to a lipofuscin substance found in the fat

Tuberculosis Cutis with Papulonecrotic Sarcoid-Like and Colliquative Lesions Presented by DR S B FRISCHBERG

Alopecia Congenita Presented by DR C T CHIARAMONTE

D B, a white girl aged 9 years, has scant growth of hair on the scalp and eyebrows The deficiency is more evident in the frontal region There is pronounced follicular keratosis on the nape of the neck The child weighed 6 pounds, 2 ounces (2,778 Gm) at birth, was a breech presentation at delivery and gained weight more slowly than the average infant Since birth the hair on the scalp had always been sparse

The laboratory examination revealed absence of arsenic in the urine, a basal metabolism of + 13 per cent and a normal reaction for specific dynamic action of proteins A roentgengram of the sella turcica was normal

DISCUSSION

DR SEYMOUR H SILVERS Often, in addition to absence of or sparse hair, other ectodermal defects are seen It is not unusual to observe alopecia with dental and ophthalmic defects This child is mentally alert and bright.

DR JOEL SCHWEIG I am in favor of the diagnosis of the presenter, but I would advise cultures be made from the scalp and hair as the picture may turn out to be one of favus

Fig 5—Hyperkeratotic growths of pachyonychia congenita in a boy aged 16

Fig 6—Dyskeratotic toe nails and finger nails in same boy as in figure 5

Epidermolysis Bullosa Congenita Presented by DR C T CHIARAMONTE

G O, a white boy aged 4 years, has numerous bullae on the dorsum of the feet, some of which are hemorrhagic The toe nails and finger nails show atrophic and dystrophic changes Healed, erythematous lesions may be seen on the elbows and knees

There is no consanguinity of the parents It is interesting to note that this child has a nonidentical twin brother who is normal This child was first observed a few days after birth At that time, there were numerous cloudy bullous lesions scattered on the body, which I diagnosed as pemphigus neonatorum Culture from the bullae revealed the presence of Staphylococcus albus The lesions disappeared after treatment with sulfonamide drugs locally and internally Since then, however, blisters have been noticed by the parents to be reappearing on the extensor surfaces of the elbows and knees, on the dorsa of the feet and in the mouth

A Case for Diagnosis (Hodgkin's Disease?) Presented by DR C T CHIARAMONTE

L A, a white man aged 43 years, has a generalized, itchy eruption consisting of isolated, large, serrated papules These papules are brownish red, and some of them are excoriated There are also irregular groups of large vesicles, the tops of many present a small yellowish crust located on the extensor surfaces of both legs, arms and forearms and on the dorsa of the hands On the thighs the lesions have spread peripherally and form patches of crusted vesicles Groups of vesicles are present on the face, chest and abdomen Several of the original lesions have left a brownish pigmentation

The patient has had papular lesions and itching for the past seven months He first presented himself for treatment in January 1947, after having been treated elsewhere for scabies The past history reveals that the patient has had pulmonary tuberculosis, which was recognized in 1928 and was pronounced arrested in 1935, after a phrenicectomy In 1943 he received treatment for spastic colitis

A recent roentgenogram of the chest and examination of the gastric contents for tubercle bacilli did not reveal any abnormalities A biopsy of one of the papules performed in March revealed moderate acanthosis and parakeratosis with some hyperkeratosis The epidermis was infiltrated with eosinophils The corium contained many eosinophils, round cells and proliferating fibroblasts This inflammatory infiltrate was grouped around the small blood vessels The results of the urinalysis and hemogram were within normal limits The cholesterol content of the blood was 197 8 mg per hundred cubic centimeters and the cholesterol esters were 67 9 mg Roentgenograms of the long bones showed no abnormalities

DISCUSSION

DR C T CHIARAMONTE The biopsy was performed on one of the nodular purplish brown, persistent lesions I have known of cases of early Hodgkin's disease which was mistaken for scabies The patchy eruption on the arms, forearms and legs has appeared only in the past two months I shall observe him closely In the past few months, there has been a rise in the white blood cell count

DR NATHAN PENSKY The suggestion of Dr Chiaramonte must be seriously considered Several articles in the current literature have appeared on eosinophilic granuloma However, I have seen a number of patients who have been overtreated for scabies in which an eczematized eruption developed which clinically resembled

Incontinentia Pigmenti Presented by DR J GARDNER HOPKINS

J A M, a girl aged 5½ months from the Vanderbilt Clinic, was previously presented by Dr Helen O Curth before the Section of Dermatology and Syphilology of the New York Academy of Medicine on March 4, 1947

Most noticeable on the inner aspect of the thighs but visible also on the sides of the trunk are wavy parallel bands of hyperpigmentation in typical zebra pattern The skin is otherwise normal

DISCUSSION

DR FRED WEIDMAN, Philadelphia A number of years ago I performed an autopsy on an infant with peculiar transverse bands of pigment across the abdomen, but in paraffin sections I could not find the pigment which was to be expected Perhaps Dr Hopkins has had the same experience, because in his sections the pigment was inconspicuous However, in frozen sections, it was conspicuous indeed It is true that melanin pigment is not supposed to be dissolved in our histologic embedding agents, but perhaps in Dr Hopkin's case, too, frozen sections would show the pigment more plainly than do the histologic sections I reported my case under the name of "Transverse Hyperpigmented Lines of the Thorax and Abdomen of a Negro Infant" in the ARCHIVES (**37** 517-523 [Aug] 1919)

DR J GARDNER HOPKINS Was the pigment in the epidermis or in the chromatophores?

DR FRED WEIDMAN, Philadelphia In the epidermis

DR GERALD F MACHACEK This type of disorder has also been reported as familial chromatophore nevus by Naegeli and as melanodermatosis congenita by Siemans

DR J GARDNER HOPKINS I do not believe that this case is parallel to Dr Weidman's It corresponds to the cases described by Naegeli and by Bloch and Sulzberger in which pigment was in the chromatophores under the skin and not in the epidermis

A Case for Diagnosis (Behcet's Syndrome? Pemphigus? Leukemia Cutis?) Presented by DR EUGENE F TRAUB

A Case for Diagnosis (Lichen Planus and/or Lupus Erythematosus of Lips and Tongue Oriental Sore of Forearm) Presented by DR MAURICE J COSTELLO

G R, presented from Bellevue Hospital, was born in the United States and was taken to Greece when he was 14 years old, where he remained until about four months ago He was a guerilla fighter during the past two years in Greece. He does not smoke

About 15 months ago an erythematous patch appeared on the patient's right forearm, persisting until about three months ago, when it developed into an ulcer After biopsy was performed at this site the ulcer healed spontaneously A hyperpigmented scar can be seen

About four months ago a small superficial red area appeared on the left side of the dorsum of the tongue It increased in size to that of a 25 cent piece, became superficially eroded with a grayish pellicle-like border, and caused some pain when the patient was eating and drinking

During the past three weeks reticulated whitish streaks on the lower lip suggestive of lichen planus have developed A small superficial erosion has recently developed on the center of the tongue, medial to the one just described There has been no regional adenopathy

the rash in the case presented tonight The histologic observations in the present case would lead one to suspect the possibility of a lymphoblastoma

DR C T CHIARAMONTE Another thing of interest is the tuberculous background I feel that Hodgkin's disease and tuberculosis are in some way related

DR JOEL SCHWEIG I have the feeling that the diagnosis of Duhring's disease is the right one, as I have seen several instances of that condition which resemble clinically the case presented tonight My suggestion is that the patients be tested with potassium iodide, internally and externally, and that he be treated with sulfapyridine

Mycosis Fungoides, Developing On Parapsoriasis(?) Presented by DR C T CHIARAMONTE

Abraham Walzer, M D, *President*
Seymour H Silvers, M D, *Secretary*
May 19, 1947

Generalized Scleroderma Presented by DR L M FRUCHTBAUM

A M, a woman aged 70, was admitted to the Unity Hospital on Jan 6, 1947, because of acute cardiac decompensation Examination revealed edema of the lungs and of the legs The patient gave a history of progressive dysphasia for the previous three years, during which time she had noticed thickening and hardening of the skin of the forehead and face with inability to open the mouth wide The patient also noticed that she was unable to smile or frown and experienced difficulty in swallowing foods, particularly hard foods The hardening of the skin extended to the neck, shoulders, chest, back and thighs Examination revealed a waxy smooth skin adherent to the underlying soft tissues on the face, neck, trunk, shoulders and thighs The fingers and toes were not affected

The hemogram was within normal limits except for a leukocyte count of 12,500 per cubic centimeter Blood chemistry studies gave normal values for sugar and cholesterol, but the urea nitrogen was elevated to 28 5 mg per hundred cubic centimeters, and creatinine to 2 mg per hundred cubic centimeters The basal metabolic rate was —36 per cent The urine was normal Histologic examination of a specimen of skin showed scleroderma

DISCUSSION

DR JOEL SCHWEIG In view of the fact that there is so much edema present on the neck, as well as the lower extremities, I feel that the process is a deep-seated one and may be scleredema of the infectious type as described by Buschke Should it be of infectious origin, treatment with penicillin or sulfonamide drugs would be indicated and the prognosis would be more favorable A biopsy should aid in the final diagnosis

DR JACOB SKEER I also believe that there is too much edema present and that the extension of the lesion was rather rapid By this time there should be contracture of the tissues and other signs, like pigmentation The edema is of the nonpitting type and suggests Buschke's disease I think that a biopsy would give more information

DR SAMUEL I GREENBERG I think that this is scleroderma Scleredema is described in young adults, it follows infectious disease and is transient These aspects are not present in this case

Kaposi's Varicelliform Eruption in an Infant Presented by DR D V OMENS, DR S J ZAKON and (by invitation) DR H OMENS and DR N L BAKER

G V, a 4 months' old white boy, had eczema of the face since the age of 1 week Five day ago vesicles appeared on the cheeks Physical examination disclosed a mildly toxic infant The temperature ranged from 100 to 102 F rectally Groups of umbilicated vesicles situated on an erythematous base are present on the cheeks, chin and eyelids There is a cluster of pinhead-sized vesicles on the tip of the tongue

The Mantoux reaction was negative, erythrocytes were 5,230,000 and leukocytes 5,150, with 30 per cent polymorphonuclear cells, 63 per cent lymphocytes, 1 per cent eosinophils and 7 per cent monocytes

On March 18, 1947, a rabbit's eye was scarified and inoculated with blister fluid from one of the lesions

DISCUSSION

DR M H EBERT I believe that this is an instance of Kaposi's varicelliform eruption The herpetiform vesicles in this condition are of short duration because they are quickly erupted The vesicles in the mouth occur in groups as they do in ordinary herpes Ordinarily this eruption is associated with a considerable rise in temperature and with more toxemia than is present in this patient Penicillin has been administered and found to be of value in reducing the toxemia Dr Baker inoculated the cornea of a rabbit with material from one of the lesions Results were negative At the present moment there is no proof that this is due to infection with the herpes simplex virus Had the inoculation been positive at the end of twenty-four hours, there would be extensive involvement of the cornea of the rabbit with inflammatory exudate If the cornea is then removed and fixed with Zenker's solution or mercuric chloride in alcohol, the sections will show nuclear inclusions in the epithelial layers at the site of the scratch marks identical with the inclusions that are present in the early lesions of ordinary simplex

DR FRANCIS W LYNCH, St Paul In such a case one may reasonably question whether the eruption is the result of virus infection or pyogenic infection or both Umbilication of vesicles is seen in some superficial pyodermas and apparently a few such cases have been reported as of Kaposi's varicelliform eruption In one instance an epidemic of such cases was reported In recent years a number of workers have demonstrated the herpetic virus in patients with Kaposi's disease, but none claim it to be the only cause, pyogenic infection could become superimposed

In this case of Dr Omens and Dr Baker, the grouping of the lesions in the submaxillary area and the eruption on the tongue make me think that the condition is herpetic It is odd that the patient is not more ill, as the first herpetic infection, even when localized, usually produces considerable febrile reaction It may be possible to find the source of the infection by questioning or examination of the persons who had recently handled the child In such a young child the source should be exogenous rather than endogenous

DR S J ZAKON I saw this baby four days ago, and his temperature was 105 F rectally The child was then much more toxic When I saw him two days later, after two days of penicillin therapy, he had improved very much

DR J E GINSBERG I would like to ask Dr Lynch about the prognosis Would you hesitate to hospitalize such a patient without isolation?

DR FRANCIS LYNCH I would not hospitalize such a patient without isolation I think that herpes simplex should be regarded as an infectious disease, and on a

DR DAVID M DAVIDSON I think that this is scleroderma The patient also has cardiac disease, and the pitting of the legs has nothing to do with her scleroderma I do not believe that this is scleredema of Buschke because the duration of the condition is three years and there is no history of a preceding infection

Urticaria Pigmentosa Presented by DR L M FRUCHTBAUM

DISCUSSION

DR C B LOCASTO It has been found that in animals given a diet free of vitamin A large numbers of mast cells develop in the tissues of the body In view of this, it is suggested that the patient receive large doses of vitamin A

Case for Diagnosis (Granuloma Annulare?). Presented by DR L M FRUCHTBAUM

Case for Diagnosis (Necrobiosis Lipoidica Diabeticorum? Granuloma Annulare?) Presented by DR I N HOLTZMAN

The patient, a white housewife aged 51, was first seen in the outpatient department of the Jewish Hospital of Brooklyn on May 12, 1947, with the following history

About five weeks prior to admission, she first noticed a nonitching eruption on both forearms and eyelids, which followed a mild abrasion of the left forearm The eruption has remained unchanged since its onset Her past history revealed the existence of diabetes mellitus of at least ten years' duration and a mild hemostatic eczema of the right ankle of about seven years' duration

Examination on admission revealed a papular eruption on the volar aspect of both forearms and eyelids The lesions varied in size from that of a pinhead to that of a pea and were faintly erythematous, and the larger papules were slightly yellow There was no characteristic grouping or configuration of any of the lesions

A biopsy of a lesion of the left forearm showed degeneration, necrobiosis and homogenization of the collagen with nuclear debris Surrounding and infiltrating into this zone were large collections of epithelioid foam cells Small round cells were occasionally seen Blood chemistry studies revealed a concentration of sugar of 181 mg and cholesterol of 261 mg per hundred cubic centimeters

DISCUSSION

DR JOEL SCHWEIG In my opinion the clinical features of the case fit in well with the diagnosis of lichen ruber moniliformis, which was well reviewed by Wise and Rein in 1936 The shape of the lesions, the color and the distribution are typical Although there is only one area on the right wrist presenting the moniliform features, it should be considered lichen ruber moniliformis, as those features may appear later in abundance The histologic observations are also like the microscopic features of lichen ruber moniliformis

DR DAVID M DAVIDSON When the patient was first seen at the clinic, a few diagnoses were mentioned, among them lichen moniliformis and lichenoid sarcoid When I examined the slide and saw that the main histologic changes

Kaposi's Varicelliform Eruption in an Infant Presented by DR D V OMENS, DR S J ZAKON and (by invitation) DR H OMENS and DR N L BAKER

G V, a 4 months' old white boy, had eczema of the face since the age of 1 week Five day ago vesicles appeared on the cheeks Physical examination disclosed a mildly toxic infant The temperature ranged from 100 to 102 F rectally Groups of umbilicated vesicles situated on an erythematous base are present on the cheeks, chin and eyelids There is a cluster of pinhead-sized vesicles on the tip of the tongue

The Mantoux reaction was negative, erythrocytes were 5,230,000 and leukocytes 5,150, with 30 per cent polymorphonuclear cells, 63 per cent lymphocytes, 1 per cent eosinophils and 7 per cent monocytes

On March 18, 1947, a rabbit's eye was scarified and inoculated with blister fluid from one of the lesions

DISCUSSION

DR M H EBERT I believe that this is an instance of Kaposi's varicelliform eruption The herpetiform vesicles in this condition are of short duration because they are quickly erupted The vesicles in the mouth occur in groups as they do in ordinary herpes Ordinarily this eruption is associated with a considerable rise in temperature and with more toxemia than is present in this patient Penicillin has been administered and found to be of value in reducing the toxemia Dr Baker inoculated the cornea of a rabbit with material from one of the lesions Results were negative At the present moment there is no proof that this is due to infection with the herpes simplex virus Had the inoculation been positive at the end of twenty-four hours, there would be extensive involvement of the cornea of the rabbit with inflammatory exudate If the cornea is then removed and fixed with Zenker's solution or mercuric chloride in alcohol, the sections will show nuclear inclusions in the epithelial layers at the site of the scratch marks identical with the inclusions that are present in the early lesions of ordinary simplex

DR FRANCIS W LYNCH, St Paul In such a case one may reasonably question whether the eruption is the result of virus infection or pyogenic infection or both Umbilication of vesicles is seen in some superficial pyodermas and apparently a few such cases have been reported as of Kaposi's varicelliform eruption In one instance an epidemic of such cases was reported In recent years a number of workers have demonstrated the herpetic virus in patients with Kaposi's disease, but none claim it to be the only cause, pyogenic infection could become superimposed

In this case of Dr Omens and Dr Baker, the grouping of the lesions in the submaxillary area and the eruption on the tongue make me think that the condition is herpetic It is odd that the patient is not more ill, as the first herpetic infection, even when localized, usually produces considerable febrile reaction It may be possible to find the source of the infection by questioning or examination of the persons who had recently handled the child In such a young child the source should be exogenous rather than endogenous

DR S J ZAKON I saw this baby four days ago, and his temperature was 105 F rectally The child was then much more toxic When I saw him two days later, after two days of penicillin therapy, he had improved very much

DR J E GINSBERG I would like to ask Dr Lynch about the prognosis Would you hesitate to hospitalize such a patient without isolation?

DR FRANCIS LYNCH I would not hospitalize such a patient without isolation I think that herpes simplex should be regarded as an infectious disease, and on a

consisted of local granular necrosis with cellular debris surrounded by many epithelioid cells and a few connective tissue cells, I was inclined to consider the case as one of granuloma annulare, although the patient did not have any ring lesions I have seen a few patients with granuloma annulare with scattered papules, but they also had the typical annular lesions However, Hartzell (*J A M A* **63** 230 [July 18] 1914) and Stilhans (*J Cutan Dis* **37** 580, 1919) each reported a case of granuloma annulare without ring lesions, and the latter mentioned many others who had observed similar cases

The patient has definite lichenoid papules, some resembling lichen planus, although the lesions are softer to the touch than those in lichen planus There is no moniliform arrangement and no waxy papules as were described in lichen moniliformis Another interesting point in this case is that the patient has diabetes but clinically the lesions do not suggest necrobiosis lipoidica diabeticorum, and histologically one often finds extensive vascular damage in necrobiosis as well as in lichen moniliformis, features not found in this case and usually not seen in granuloma annulare In consideration of all this, I am inclined to consider this as a case of granuloma annulare

Xanthoma Tuberosum Presented by Dr L M Fruchtbaum

Epithelioma of the Cheek in a Woman Aged Twenty Years Presented by Dr Seymour H Silvers

Acrokeratosis Verruciformis of Hopf Presented by Dr C B Locasto

M C, a Negro woman aged 52, stated that she has had thick skin on the palms and soles and wartlike growths on the back of her hands since birth There are no subjective symptoms The palmar and plantar surfaces are hyperkeratotic The dorsal aspects of the hands and feet and the distal parts of the forearms are studded with numerous, discrete, confluent and flat-topped verrucalike polygonal papules The nails are frayed distally, have vertical linear striations and are brittle

DISCUSSION

Dr Joel Schweig This is an unusual case and of a type rarely seen at our meetings I agree with the diagnosis Acrokeratosis verruciformis and epidermodysplasia verruciformis are different in that the latter appears in persons with consanguineous parents and is associated with malignant degeneration of the lesions The concept of this condition is that it is of nevoid character

Tinea Capitis in an Adult (Microsporon Lanosum) Presented by Dr E A Gauvain

T A, a widow aged 73, had been losing hair for four months She complained of slight itching of the scalp She had no recollection of direct contact with dogs or cats, but a dog had been a recent visitor to one of her neighbors

The hair of the scalp is thick and long, with many areas showing slight erythema and definite defluvium without any sharply defined areas of alopecia Under the Wood light, fluorescent hairs mingled with nonfluorescent hairs are seen throughout the scalp A culture of infected hair grew Microsporon lanosum

dermatologic service the patient should be isolated I am sure that I have seen the infection carried by and transferred by attendants

Tuberculosis Colliquativa of the Sternum in an Eleven Year Old Negro Girl Presented by DR D V OMENS and (by invitation) DR H OMENS and DR B YAFFEE

Generalized Acne Scrofulosorum, Ecthyma Presented by DR F E SENEAR and STAFF

R S, a 4 year old Negro boy, was admitted to the Illinois Research and Educational Hospitals for the treatment of tuberculosis of the right hip For six months a generalized eruption had been present and large ulcerations had appeared on both legs

Examination revealed numerous folliculopapular lesions distributed over the entire cutaneous surface but most concentrated on the extensor surfaces of the extremities A few lesions exhibited central necrosis, older lesions were represented by slightly depressed scars, depigmented at the centers and with hyperpigmented borders A fading eruption of tiny lichenoid papules was present on the sides of the trunk Large granulating ulcers were noted over the anterior aspects of both legs

A bullous reaction developed after skin testing with 1 10,000 old tuberculin The report of biopsy is not yet available

DISCUSSION

DR H E MICHELSON, Minneapolis It has never been clear to me why certain types of tuberculosis respond to roentgen therapy and others do not For example, bone and most skin lesions do not respond while glandular tuberculosis and certain peritoneal types do There are many other facts about glandular tuberculosis that are most interesting, especially the seasonal incidence One does not see many patients with generalized tuberculous eruptions Recently Schmidt wrote a good article on these eruptions in the German dermatology journal (*Archiv für Dermatologie und Syphilis*)

Dermatitis in Red Area of Tattoo, Reaction Positive to Patch Test with Ammoniated Mercury, Negative with Cinnabar Presented by (by invitation) DR EVERETT T DUNCAN and DR CLARK F JOHNSON

Psoriasis Verrucosa, Arthropathy and Koebner's Phenomenon Presented by DR S ROTHMAN and (by invitation) DR J MCCREARY

DISCUSSION

DR MARY S SHERMAN It is variously estimated that 2 to 4 per cent of patients with symptoms of chronic arthritis have psoriasis Conversely up to 12 per cent of patients with psoriasis may be expected to have joint symptoms at one time or another Since the joints are rarely involved severely enough so that operation is indicated, reports of the pathologic changes are few

The clinical characteristics of so-called psoriatic arthritis are well known Males are affected more than females Although any joint or combination of joints may be involved, the joints most commonly and characteristically troublesome are the terminal interphalangeal joints of fingers and toes, and there are usually associated typical nail changes It is especially noteworthy that the joint

CHICAGO DERMATOLOGICAL SOCIETY

Francis W Lynch, M D, *President*

Leonard F Weber, M D, *Secretary*

Feb 19, 1947

Pemphigus Vulgaris Presented by DR M H EBERT and (by invitation) DR N L BAKER

A Case for Diagnosis (Erythema Perstans?). Presented by DR T CORNBLEET and (by invitation) DR D COHEN and DR J GRAFFIN

Lupus Pernio? Presented by DR S ROTHMAN and (by invitation) DR Z FELSHER and DR L RUBIN

Sarcoidosis, Keloidal Nodules on the Nose of a Young Negro Woman Presented by DR H RATTNER and (by invitation) DR H RODIN and DR J GRAFFIN

A Case for Diagnosis (Lupus Erythematosus in a Girl of 17 Years). Presented by DR D OMENS, DR S J ZAKON and (by invitation) DR H OMENS and DR J GRAFFIN

Systemic Blastomycosis Presented by DR D OMENS and (by invitation) DR H OMENS and DR J GRAFFIN

S W, a Negro woman aged 39, on Dec 24, 1946 precipitously delivered a full term baby while on the street Several days later she noticed a few nodules on the right forearm, which gradually grew to form abscesses In the next two months numerous fluctuant, hen's-egg-sized abscesses appeared on the face and extremities, and, in addition, warty lesions developed on the face and trunk For the past few weeks she has had fever, "night sweats," headache and malaise, but no symptoms referable to her gastrointestinal, respiratory or genitourinary tract Until the time she entered the Cook County Hospital, she had nursed her apparently healthy baby Her other four children and her husband have been in good health She has not been out of Chicago in the past two years and has no contact with flowers, gardening or animals

Examination reveals numerous fluctuant, tender, subcutaneous abscesses scattered on the face, extremities and back, varying from 1 to 5 cm in diameter In addition, there are verrucous nodules on the face and trunk Physical examination revealed no other abnormalities While in the hospital she has had a low grade fever daily, accompanied with headache and malaise

The Kahn reaction of the blood was negative The urine was normal The blood examination showed erythrocytes 4,600,000, hemoglobin 67 per cent and leukocytes 22,200 Sterile aspiration of a subcutaneous abscess resulted in recovery of blastomycetes on culture Direct sodium hydroxide preparation revealed numerous round doubly refractile bodies, some of which were budding The blastomycin intracutaneous test revealed a 12 mm erythematous papule at 24 hours, but at 48 hours the papule was only 5 mm in diameter The roentgenogram of the chest revealed a normal cardiothoracic ratio There was a small discrete

manifestations do not respond to treatment directed toward the arthritis, but improve miraculously as the cutaneous lesions subside

As a rule, therefore, the arthritic manifestations subside between exacerbations of the cutaneous lesions and in the intervals there are usually no symptoms of permanent residual damage Occasionally the joints are irritated sufficiently so that they do not return to normal, and there have been reports of complete ankylosis

In the present case arthritic symptoms appeared at the early age of 17, one and a half years after the onset of the cutaneous disease The psoriasis was essentially untreated and grew progressively worse During the next two and a half years, more and more joints became involved, and none of them improved The patient had been completly incapacitated by the pain in his knees

The roentgenograms of this boy's knees show little other than regional atrophy and beginning degenerative changes The cartilage space is well preserved, but there is irregularity of the articulating surface of the patella and small osteophytes forming at its periphery The roentgenograms of the hands show more typical changes In the right hand the terminal two joints of the fifth finger have been largely destroyed and marginal absorption of the ends of the phalanges is evident. In the left hand similar changes are observed in the terminal joint of the long finger and in all the joints of the index finger In the metacarpophalangeal joint there has been peripheral destruction of the articular cortex, so that only the central portion is visible

When biopsy of the right knee joint was undertaken, the cutaneous lesions had begun to show some improvement Exploration of the knee joint revealed gross damage There was severe synovitis which had resulted in dense adhesions The synovial membrane had grown over the joint surfaces, so that the tibia was scarcely visible The patella was encircled by numerous osteophytes and its articular cartilage was completely destroyed except for a few soft gelatinous remnants What was visible of the surfaces of the tibia and femur appeared to be normal This first section is from the synovial membrane It shows the grossly hypertrophied villi The most striking change is the great amount of well organized, vascular, fibrous thickening, with relatively few signs of inflammation, an observation which was noted by Bauer and his associates The blood vessels are also somewhat sclerotic This is in contrast to the chronic inflammatory character of this synovial membrane taken from a patient with Still's rheumatoid arthritis

A piece of bone and cartilage was removed from the edge of the femoral condyle in an area where the articulating surface looked normal, but the section reveals advanced changes No articular cartilage remains It has been entirely replaced by a collagenous type of fibrocartilage which contains numerous blood vessels Beneath the cortex is seen a sort of chronic granulation tissue Between these two the bony cortex has been thinned to a narrow plate, which in one spot is almost disrupted

It is, of course, not possible to say whether these changes are characteristic of psoriasis They are certainly not like those one associates with rheumatoid arthritis In fact, they are not quite like any of the known chronic arthritides It will take further study before we understand how this appearance is produced and what it means

Psoriasis Verrucosa, Developing During Treatment Presented by DR S ROTHMAN and (by invitation) DR L RUBIN

DISCUSSION

DR STEPHEN ROTHMAN The relationship between psoriasis and arthropathia according to Julius Bauer is due to debility of conjugated genes He published

density visualized in the left apical region superimposed on the posterior border of the third left rib, with the suggestion of a drainage band extending to the left hilus

Histologic section revealed acanthosis with edema of the prickle cell layer The corium is edematous and contains a cellular infiltrate composed of lymphocytes, plasma cells and leukocytes Deep in the corium there are numerous double contour bodies with a few giant cells

DISCUSSION

DR. OLIVER S ORMSBY I had been practicing only about a year when I was called to see a patient who was supposed to have tuberculosis A man of middle age had lesions on the face and on the extremities The lesions on the face were fairly typical of blastomycosis, but the lesions on the extremities were very different In those areas there were subcutaneous nodules, abscesses and ulcers, with pus oozing out of the lesions I took a specimen to the office and demonstrated Blastomyces The patient was very ill and died shortly thereafter At autopsy I was able to demonstrate Blastomyces in the lungs, liver, spleen, kidneys and bones That was the first case on record in which there was systemic blastomycosis involving all the tissues

During the next three or four years I saw 4 or 5 more cases, and it was shown that this organism attacks every tissue in the body At autopsy the doctor in charge pricked his finger, and within a little while blastomycosis developed in that finger, and within two or three months he had systemic blastomycosis In our early experience practically 100 per cent of the patients died Since that time a certain percentage recover

DR M J REUTER, Milwaukee One of our residents checked over our records on systemic blastomycosis and was able to find 38 cases of the generalized type Of this number he was able to trace 26 One patient is still alive after ten years and another is alive after two years

Paraffinoma Presented by DR T CORNBLEET and (by invitation) DR D COHEN and DR J GRAFFIN

C H, a white woman aged 63, about twenty-five years ago, had wax injected into both cheeks and the forehead for cosmetic purposes At present she is in a medical ward at the Cook County Hospital with arteriosclerotic heart disease and possible endocrine disturbance Examination revealed a firm mass, 5 cm in diameter, in both cheeks, and a smaller one between the eyebrows The overlying skin is bound down to the masses and is bluish red

The Kahn reaction of the blood was negative The urine was normal The electrocardiogram reveals myocardial damage Histologic sections from the mass in the cheek are presented

DISCUSSION

DR OLIVER S ORMSBY I saw one of those cases in my early experience It was only the second case that had been seen in this country My co-workers and I were fortunate enough to get a section which showed the typical sievelike arrangement where the paraffin entered the connective tissue This woman was very handsome, and she decided to have some dimples put in each side and to have some wrinkles taken out A half dozen large tumors developed A plastic surgeon removed them, and the result was very good At a later date we saw tumors from paraffin oil used for injection

DR S J ZAKON There are a lot of Romansky injections being given in the treatment of syphilis and other diseases with penicillin in large doses I have seen

the pedigree of a family in which some members had psoriasis, others arthritis and one member arthropathic psoriasis The peculiar observations of the biopsy of the joints will be reported by our orthopedic department In 1 case the verrucous lesions developed the second time around healing psoriatic lesions

Eosinophilic Granuloma Presented by DR EDWARD A OLIVER and (by invitation) DR E LORANT

M E C, a white man aged 42, first noticed a few reddish lesions on his face in January 1943 The lesions developed slowly, and the patient was kept under observation in a Naval dispensary A biopsy was performed in September 1943 and another in March 1944 On both occasions the diagnosis on pathologic examination was "chronic inflammation, probably mycosis fungoides"

From October to December 1943, he had eight roentgen irradiations at weekly intervals, of 75 r each After completion of the irradiations the lesions flattened and changed color from cherry red to pinkish brown However, three months after the roentgen therapy was completed the lesions became active again and have shown occasional activity to date

The patient now shows a quarter-sized lesion on the left cheek, another irregularly shaped quarter-sized lesion on the right cheek and a larger lesion in front of the right ear on the temporal region These lesions are nonelevated and reddish brown and are yellowish brown on pressure with a diascope They are not pruritic

The general physical examination and roentgenograms of the chest, feet and hands showed no evidence of pathologic changes

The urine was normal Examination of the blood showed a hemoglobin content of 87 to 90 per cent, a color index of 0 9, an erythrocyte count of 4,500,000 to 4,600,000 and a leukocyte count of 6,000 to 9,600, with a differential count of 48 to 56 per cent neutrophils, 38 to 46 per cent lymphocytes and 6 per cent eosinophils The sedimentation rate was 2 to 4 mm per hour The total protein was 6 9 mg per hundred cubic centimeters of blood, with an albumin-globulin ratio of 1 7 to 1

In a recent biopsy histologic observations were as follows The epidermis was uniform and apparently not increased in thickness There was slight hyperkeratosis The basal cells were well preserved, with a small amount of pigment present

In the corium completely separated from the epidermis there were large and small clusters of cells as well as cellular infiltrations composed of numerous lymphocytes, an occasional eosinophil, a few plasma cells and a few neutrophils were seen also The blood vessels and lymphatics were slightly dilated and presented occasional perivascular infiltrate There was slight edema throughout the corium The sebaceous and sweat glands were not especially involved

Histologic examination showed the epidermis to be normal In the middle portion of the corium, separated from the epidermis by a narrow band of normal connective tissue, lay a wide horizontal band of cellular infiltrate This cellular mass was densely packed, it was sharply circumscribed, and it included within its borders hairs and sebaceous glands There were many eosinophilic polymorphonuclear and mononuclear cells and many lymphocytes and histiocytes and fewer plasma cells

DISCUSSION

DR H M BULEY, Champaign, Ill During the past eighteen months my co-workers and I have had the opportunity to see several cases of eosinophilic granuloma of the skin representing various types of eruptions As has been stated in previous discussions, it is extremely difficult to find the common denominator for the various pictures presented in these cases I feel, therefore, that it is some-

a number of severe reactions in the buttocks following such injections The reactions would subside in a couple of weeks I wonder whether fifteen or twenty years from now one will see lesions similar to paraffinoma due to Romansky injections

DR STEPHEN ROTHMAN With vegetable oil and fatty acids paraffinoma does not occur Paraffinoma occurs exclusively with hydrocarbons I doubt whether white wax would produce paraffinoma, because such wax is composed of fatty acid

DR THEODORE CORNBLEET It is my feeling that one need not expect the same accidents to happen from the Romansky formula as from paraffin itself With paraffinoma there is no initial reaction, whereas with white wax one commonly finds a reaction in the tissues Originally, I tried to arrange to have a fluorescent light to detect the presence of the paraffin, which shows a Swiss cheese structure

Sporotrichosis Involving the Face and All Extremities Presented by DR MICHAEL H EBERT and (by invitation) DR N L BAKER

Dermatomycosis (?) Localized to Flexural Areas for Twenty Years Presented by DR H RATTNER and (by invitation) DR H RODIN and DR N L BAKER

Acute Disseminated Lupus Erythematosus in a Man Aged 37 Years Presented by DR MICHAEL H EBERT and (by invitation) DR N L BAKER

A Case for Diagnosis (Eruption Due to Drugs? Hemorrhagic Lupus Erythematosus? Toxic Purpuric Disease of Undetermined Origin?) Presented by DR S ROTHMAN and (by invitation) DR L RUBIN

Keratosis Follicularis (Darier?), Improved After Ingestion of Butter in Large Quantities Presented (by invitation) by DR H H RODIN

Recurrent Alopecia Areata Presented by DR E M SMITH JR

D D, a white boy, aged 7, rather small for his age, has a recurrent patch of alopecia areata involving the vertex and the strip down the center of his scalp toward the front This condition has occurred every September or October for the past five years and has run a course of about two or three months The configuration of hair loss is practically the same, and there is a complete clearing up of the condition between times

DISCUSSION

DR STEPHEN ROTHMAN I thought that definitely the boy had trichotillomania and that he had done a good job for himself

DR E M RUSTEN, Minneapolis I have a patient who is a resident in a tuberculosis sanatorium In 1928 he had pulmonary tunberculosis with bilateral effusion and rather extensive alopecia areata The pulmonary tuberculosis was controlled by sanatorium treatment, and he had a recurrence of hair growth About a year ago he had a recurrence of the pulmonary disease and again had alopecia areata His pulmonary disease is now improving, and his hair has also returned

DR JAMES R WEBSTER When I first saw the patient this afternoon I had the impression that the condition was trichotillomania, but on further examination concluded it was alopecia areata

what premature to suggest common causative factors, at least not until a larger number of case studies have been accumulated The case presented today is comparable to the case described by Pasini in 1940, and also with the case I presented here in November 1945 In these 3 patients the eruption started with macular erythema on the face, which within several months changed to a more or less extensive papular or nodular form Once the lesions reached their maximum size, however, they maintained their clinical appearance It is further remarkable that the disease did not interfere with the patients' general health No pathologic changes were found in either the lungs or the bones Although there was a slight increase in the eosinophil count of the blood the disease was essentially confined to the skin In all 3 cases the lesions were indolent, causing no discomfort to the patient In the patient presented today, relative lymphocytosis (30 to 40 per cent) was found, which, as far as I can recall, had not been noted in the other cases

DR CARL W LAYMON, Minneapolis There have been less than a dozen cases of eosinophilic granuloma of the skin in the literature, and the association of eosinophilic granuloma of the skin and bone is extremely rare The clinical picture of eosinophilic granuloma of the skin is subject to wide variations The lesions may be papules, nodules or plaques which are smooth or verrucous and usually red, purple or brown In the case recently reported by Dr Lewis and Dr Cormia there seemed to be an association between the eosinophilic granuloma and a fungous infection of the feet These observers suggestd that possibly eosinophilic grauloma of the skin might be linked to allergy of infection

DR EDWARD A OLIVER In this case the disease was difficult to diagnose clinically The patient stated that he had been treated in the Navy for mycosis fungoides He had received eight roentgen treatments I knew that it was not mycosis fungoides, and my first impression was that it was sarcoid Dr Caro then examined the sections for me, and his diagnosis was eosinophilic granuloma Dr Buley recently published an excellent article on eosinophilic granuloma in the December 1946 issue of the *Journal of Investigative Dermatology* This disease is most difficult to diagnose clinically because it occurs in so many different forms Only by a careful study of microscopic sections can one be sure of the diagnosis

Urticaria Pigmentosa of Recent Origin in an Adult, with No Mast Cells in the Section Presented by DR S J ZAKON and (by invitation) DR A L GOLDBERG

A Case of Urticaria Pigmentosa in a Child, with Mast Cells in the Corium. Presented by DR E A OLIVER and (by invitation) DR H F GARRARD

Preauricular Sinus Congenita (Bilateral) Presented by DR CLEVELAND J WHITE

Hyperplasia of the Gums Due to the Use of Dilantin® Sodium (Diphenylhydantoin Sodium) Presented by DR E M SMITH JR

DISCUSSION

DR ADOLPH ROSTENBERG JR (by invitation) Dilantin® is chemically closely related to the German drug nirvanol (phenylethylhydantoin) Van Wyk and Hoffmann (Periarteritis Nodosa, *Arch Int Med* **81** 605, 1948) pointed out the paucity of reactions seen with dilantin® and the large number seen with nirvanol, which is interesting considering the extremely close chemical relationship

DR FREDERICK R SCHMIDT At one time my co-workers and I collected 9 cases of alopecia areata which recurred regularly in September and March of succeeding years, which was apparently a type of arterial spasm, due to poor nutrition of the end arteries

DR E M SMITH JR It would be impossible for the patient to pull out the hair I have seen two recurrences, and they are absolutely the same, in that they run right down the middle of the scalp and extend only to the right side and not the left

Multiple Nevi (Adenoma Sebaceum) (Dermatosis Papulosa Nigra and Fibroma Pendulum) in a Negro Presented by DR E A OLIVER and (by invitation) DR E LORANT and DR A B HENNINGSEN

Lymphoblastoma Cutis with Poikilodermatous Changes Presented by DR F E SENEAR and STAFF

Ainhum of Two Years' Duration in a Negro Aged 66 Years Presented (by invitation) by DR MAURICE OPPENHEIM and DR DAVID COHEN

A Case for Diagnosis (Unilateral Vascular Nevus? Angioma Serpiginosum? Schamberg's Disease?) Presented by DR F E SENEAR and STAFF

Ichthyosiform Erythroderma? Presented by DR S ROTHMAN and (by invitation) DR J H MCCREARY

Localized Myxedema, Pretibial, Following Thyroidectomy Presented by DR F E SENEAR and STAFF

Probable Triple Symptom Complex of Behcet, Scrotal Tongue Presented by DR F E SENEAR and STAFF

A I, a white housewife aged 25, was shown at the December meeting of this society with a condition for diagnosis She gave a five months' history of recurrent ulcerative lesions of the mouth which had not responded to various local treatments or to intravenous treatment for a diagnosis of "trench mouth" made prior to admission At the time of presentation, she showed a marginal scrotal tongue with whitish patches of membrane extending from some of the crypts of the tongue, as well as scattered on the buccal mucous membranes These were relatively easily removed, leaving superficial tender ulcerations without bleeding and surrounded by an erythematous halo Direct examinations did not reveal mycelia During the discussion the following diagnoses were mentioned as possibilities (1) aphthous stomatitis, (2) moniliasis, (3) eruption due to drugs, (4) Behcet's triple symptom complex and (5) scrotal tongue

Medical consultation revealed nothing contributory The urine was normal, blood cell counts were normal, the results of the serologic test for syphilis and examination of the chest were all negative Examination by the gynecologic consultant showed only chronic cervicitis Repeated cultures from the mouth lesions failed to demonstrate Monilia, although cultures from vaginal discharge on one occassion did grow mucoid colonies with budding forms on microscopic examination On one occasion, the patient complained of soreness about the vulva,

DR S J ZAKON I wonder whether dilantin® is responsible for the hyperplasia or the poor oral hygiene of epileptic persons I had 1 case of this type which I referred to the dentist for oral prophylaxis, and the hypertrophy subsided in spite of the patient's taking dilantin®

DR STEPHAN ROTHMAN I saw a severe generalized hemorrhagic toxic eruption following the use of dilantin,® but the patient did not display hypertrophy of the gums

DR E M SMITH JR This patient was examined by several dentists, who readily agreed that the hypertrophy was a typical result of the long-continued use of dilantin® sodium and that such cases were moderately common in their experience

Dermatomyositis with Slightly Lichenified Lesions on Exposed Surfaces Presented by DR F E SENEAR and STAFF

Lymphocytoma Presented by DR O H FOERSTER, DR H R FOERSTER and (by invitation) DR D M RUCH

D E, a white woman aged 38, had a "pimple" on the right lateral aspect of the forehead in 1938 which she picked and scratched This became hard and raised and remained pea sized until 1945 Since then it has grown gradually, until it is now about four times its original size In 1942 a similar lesion appeared suddenly on the right side of the forehead above the original lesion, and in April 1946 a third similar lesion appeared lateral to the first one Neither of the latter two lesions have changed in size or appearance

On the right lateral aspect of the forehead, 2 cm above the lateral supraorbital margin, is a smooth, firm, cutaneous nodule, elevated about 4 mm Two similar round 5 mm lesions are also present, one 2 cm lateral to the former lesion and the other 0 5 cm above it

Histologic examination showed acanthosis to be present in some areas of the epidermis, and there was condensation in the collagen of the subpapillary layer Areas of lymphocytic infiltrates together with a few plasma cells were present about the glandular structures and in circumscribed areas deep in the corium

A blood cell count (March 18, 1947) showed hemoglobin 90 per cent, leukocytes 7,870, erythrocytes 4,590,000 and color index 1 00 The differential count showed 65 per cent neutrophils (2 per cent nonsegmented and 63 per cent segmented), 2 per cent eosinophils, no basophils, 30 per cent lymphocytes (large 1 per cent, small 29 per cent) and 3 per cent monocytes The blood smear was normal

DISCUSSION

DR M R CARO This patient presents a condition which is difficult to diagnose clinically 'The most obvious diagnosis clinically would be sarcoid, but on histologic examination these small accumulations of lymphocytic cells without any inflammatory reaction are diagnostic for lymphocytoma In the cases reported in the literature there are no observations in the blood stream to make this condition of more serious prognosis I recall a patient presented about ten years ago before this society with a lesion under the eye identical with that in the present case The lesion disappeared after three or four fractional doses of roentgen rays without any recurrence

DR ADOLPH ROSTENBERG JR (by invitation) In the eleventh supplement to 1943 Acta dermato-venereologica there is an article on lymphadenosis benigna cutis There is a fine English summary In lymphadenoma there are two varieties,

and examination in our department revealed superficial ulcerations about the labia minora and majora

On about the first of February, the patient was found to have decided injection of the right conjunctiva diagnosed as episcleritis by the ophthalmologic consultant This was considered consistent with, though not diagnostic of, Behcet's syndrome of the eye She stated that she had had one previous similar, though less severe, attack of ocular inflammation about five weeks ago

Perniones and Livedo Reticularis in a Poliomyelitic Limb Presented by Dr F E Senear and Staff

DISCUSSION

Dr M R Caro The sections were not typical of tuberculosis or tuberculid, though there were round cells which extended deeply into the fat

Dr Stephen Rothman I was very much impressed with this case because I saw quite a few after World War I in patients who had nerve injuries It shows what a profound effect trophic ulcers have on vasomotor action

Dr J F Madden, St Paul In our experience with poliomyelitis, my co-workers and I have noted that the patients have more cutaneous changes than the normal person During the acute stages in which the Sister Kenny method of therapy is used the patient often shows milaria from the hot applications

Dr F E Senear When I first saw this patient a couple of weeks ago, I thought that he had an exaggerated example of erythrocyanosis frigida crurum that the English have written about This is the first time I have seen one with so much inflammatory element that it simulated erythema exfoliativa Dr Brunner called our attention to the fact that Telford had pointed out that just this type of reaction does occur, particularly in the wasted limbs of persons who have had poliomyelitis I think, as Dr Rothman indicated, that it is a nerve injury that predisposes to this type of reaction, which is less intense than erythema exfoliativa

Eosinophilic Granuloma? Presented by Dr S Rothman and (by invitation) Dr J H McCreary

Since the age of 2 years, the patient, an 11 year old white girl, has been almost continuously sick with swelling of lymph nodes and with ulceration of the overlying skin on the head, neck and thorax The appearance of each new lesion has been accompanied with a temperature of 99 to 104 F, pain, tenderness, erythema and some swelling over the affected gland The overlying skin became red and shiny until spontaneous rupture occurred A seropurulent exudate appeared, and a crust was formed over a deep crater After rupture of the "abscess," the systemic symptoms disappeared and the temperature returned to normal There is a tendency toward slow healing with granulation and scar formation Since an operation two years ago for the removal of a group of cervical glands, the motion of the shoulders and neck has been restricted because of pain

Just previous to the onset of the present illness, the patient had measles and mumps at the same time During this illness the adenitis of the right submaxillary glands developed This adenitis failed to resolve, and formed an ulcer which persisted over twenty months Abscesses of nearby nodes followed in a similar characteristic course

Roentgen therapy seemed to accelerate healing, with remissions of the symptoms for as long as a year Dosages of the many courses of roentgen rays she received

in one there are isolated lesions such as this patient apparently has In the other variety there are multiple lesions, but in both the prognosis is about the same There is rarely systemic involvement An isolated cyst as this can arise at any age, whereas the generalized disseminated form is more often in elderly persons The author expressed the belief that a variety of stimuli are etiologic

DR HARRY FOERSTER, Milwaukee We presented this patient chiefly because of the frequency with which lesions of this type are misdiagnosed when they are not subjected to histologic study When first seen by us, the nodules appeared nevoid The history of progressive growth with appearance of new lesions in recent years, one as recently as nine months ago, suggested the possibility of endothelioma Sarcoid and sarcoma were also considered

Dr Caro made the diagnosis of lymphocytoma and also prepared the sections that were shown here today This patient received roentgen treatment about six weeks ago, and the lesions have been reduced about one third in size The pigmentation noted was caused or intensified by the roentgen therapy At the time this patient was being studied, we saw a woman with a similar lesion, and in the same site, which was shown to be an endothelioma on histologic examination

Albright's Syndrome (Fibrous Dysplasia of Bone, Precocious Puberty and Café au Lait Spots) Presented by DR F E SENEAR and STAFF

Francis W Lynch, M D, *President*

Leonard F Weber, M D, *Secretary*

April 16, 1947

A Case for Diagnosis (Streptococcic Eruption on the Face? Seborrheic Dermatitis?) Presented by DR JAMES HERBERT MITCHELL and (by invitation) DR ROBERT M GOODWIN

Pulsating Hemangiomas, Hepatic Cirrhosis Presented by DR T CORNBLEET and (by invitation) DR H SCHORR and DR J GRAFFIN

C D, a white woman aged 52, entered a medical ward at the Cook County Hospital on March 10, 1947 At this time she was given the diagnosis of cirrhosis of the liver with jaundice and ascites She was unable to give a history concerning the dermatitis of her forearms or the telangectatic lesions of her hands and face

Examination reveals a pulsating split-pea-sized lesion in the center of telangectasia on the right cheek The dorsum of the left hand has four smaller pulsating hemangiomas with a keratotic surface Both forearms and lower legs have a fairly well defined dermatitis The abdomen and chest show prominence of the superficial veins, and there are numerous telangiectases There is moderate ascites and icterus of the scleras Her temperature, while in the hospital, has steadily dropped from 102 to 99 F

The Kahn reaction of the blood was negative Repeated urinalyses revealed only a pronounced urobilinogen content The examination of the blood showed hemoglobin 58 per cent, erythrocytes 3,100,000 and leukocytes 8,100 The icterus index was 25 and 14 units The total protein was 6 1 Gm per hundred cubic centimeters, albumin 16 and globulin 4 5

The result of the cephalin flocculation test was 4 plus The nonprotein nitrogen was 31 mg per hundred cubic centimeters

so far are unknown to us Treatment with penicillin and sulfonamide drugs have had little effect on the course of the disease

The nodes have a tendency to mat together The ulcers are variable in size and shape, from 2 to 5 cm in diameter, and have a soft undermining edge and irregular granulating bases, well vascularized Some of the ulcers have appeared over regions where large lymph nodes are not usually present On the roentgenogram of the skull there is an irregular, oval dehiscence of the right parietal bone under one of the tender swellings The spleen is palpable The liver is felt at the costal margin

The axillary lymph node, seen on Jan 30, 1947, was a large moderately firm node of a peculiar red-brown The microscopic sections showed a very extensive obliteration of the normal architecture, although small remnants of cortical follicles and cords filled with lymphocytes remain These are widely separated and are missing from some parts of the node Instead one finds sheets of large acidophilic or pale nonfoamy macrophages, which seem to have filled in the sinuses as well as the parenchyma Scattered in great abundance between them are eosinophils and smaller dark cells which are presumably lymphocytes In some regions the cells with dark nuclei look more like normoblasts The histiocytes or macrophages frequently have lobulated nuclei, and sometimes they contain two or more discrete nuclei Neither in their cytoplasm nor in their nuclear form do they resemble Reed-Sternberg cells They do not possess distinct nuclei as shown in Mallory connective tissue stain, there is great fibrous thickening of the capsule and decided fibrosis of some of the cell-filled lymphatic sinuses Fibrous tissue is especially dense around the blood vessels of hilar portion of the node Evident in Mallory stain more clearly than in hematoxylin and eosin is the presence of clefts or small vacuoles of the cytoplasm of the large macrophages However, the appearance is quite different from that seen in the large cells of Gaucher's disease, in Niemann-Pick's disease or in Hand-Schüller-Christian's xanthomatosis Stains for gram-positive and acid-fast bacteria were entirely negative Sudan stain reveals an occasional macrophage containing recognizable septums A very small amount of this lipid is antisotrophic

The scraping of the sinus tract consists of multiple bits of granulation tissue and fragments of skin which show changes similar to those of the lymph nodes In the section of the skin the eosinophils are less prominent Plasma cells and large mononuclear cells are present The disease has been diagnosed once as tuberculosis by smear examination, and at another time as Hodgkin's disease by lymph node examination

In our laboratory tests, culture of the exudate on blood agar and Sabouraud's medium showed Staphylococcus albus The acid-fast stain was repeatedly negative Blood culture was negative White rat and guinea pig inoculations were repeatedly negative, results of the tuberculin patch test, blastomycin test, histoplasmin skin tests and purified protein derivative tests were all negative The Kahn reaction of the blood was negative Sternal puncture showed the myeloblast-erythroblast ratio to be elevated Other observations were sedimentation rate 41 mm in 1 hour, leukocytes 12,000, hemoglobin 12 Gm, erythrocytes 4,400,000, poloymorphonuclear cells 72 per cent, lymphocytes 26 per cent, eosinophils 2 per cent, hematocrit 41 and blood lipids 787

The histologic section from a lymph node presented a very unusual appearance which did not resemble any lymph node previously studied in our laboratories Certainly tuberculosis and Hodgkin's disease in their usual forms can be excluded On anatomic evidence at present, we have no clue as to whether this peculiar

DISCUSSION

DR S J ZAKON The internists recognize this as part of the signs and symptoms of the Chvostek Habitus (Chvostek, F Cirrohis of the Liver, *Wien Klin Wchnschr* **35** 381, 1922), in which there are ascites and jaundice, pulsating spider nevi and loss of body, axillary and pubic hair This is usually observed in nonobstructive jaundice

DR HAMILTON MONTGOMERY, Rochester, Minn My co-workers and I have seen a number of pulsating hemangiomas of the skin in patients referred by various internists in our clinic Dr Williams and Dr Snall reported a series of these cases (*Arch Int Med* **62** 872-882 [Nov] 1938) All the phenomena that have just been mentioned are not necessarily present Pulsating hemangiomas are almost invariably associated with cirrhosis of the liver

DR THEODORE CORNBLEET At the Cook County Hospital various clinicians have pointed out for years that there is a lack or sparsity of hair about the male abdomen and chest in the presence of cirrhosis of the liver My associates and I always suspect that there is cirrhosis of the liver in such cases In a number of these patients telangiectases of the chest and upper part of the abdomen and a few of the blood vessel enlargements can be seen, or more often felt, to pulsate We have tried the newer nutritional remedies for cirrhosis of the liver, such as methionine and cysteine Though some of those patients were said to be improved clinically and show better results in tests of hepatic function, I have never seen these angiomas and telangiectases disappear thereby I have seen these lesions regress, however, after parturition There is no doubt that in other cases they may clear spontaneously

A Case for Diagnosis (Lupus Erythematosus, Telangiectatic Type?) Presented by DR CLEVELAND WHITE and (by invitation) DR J L MADURA

Squamous Cell Carcinoma of the Penis Presented by DR M OPPENHEIM and DR D COHEN

Mr C P, a Negro aged 49, has a tumor-like lesion on the penis of four years' duration There is no pain but some tenderness on pressure The lesion is about the size of a half-dollar and is situated on the outside of the prepuce It has an irregular configuration, in some places polycyclic with overhanging margins There are yellowish crusts and scales on the surface When these are removed, pressure on the tumor cause white millet-sized drops to appear The lesion is indurated and of a cartilaginous consistency There is no inflammation Inguinal glands are not enlarged

On the glans penis there are depigmented, depressed, irregular scars with a smooth flat base and a slight hyperpigmentation in the periphery This lesion began as a solid nodule four years ago (1943) and has progressed until the present time In 1943 and in 1917 the patient received treatment for his blood For many years he was a laborer on a railroad, and now he is employed in an ice cream factory. No history of exposure to oil is given

The urine is normal The blood cell count is normal The Kahn reaction of the blood was negative on April 19, 1947, and on April 20, 1947

Biopsy of the skin reveals acanthosis, mainly limited to the large rete projections The prickle cell layer is growing atypically Little mitosis is present There is a dense lymphocytic infiltration in the dendritic ramifications of the papillary layer

granulomatous condition is an infection or is caused by a metabolic anomaly It more closely resembles the tissue reaction seen in eosinophilic granuloma of bone than any other condition known to us

DISCUSSION

DR CARL W LAYMON, Minneapolis There is not a great deal known about eosinophilic granuloma of the skin, since not more than a dozen cases have been reported and in those cases the diagnosis was doubtful The disease has been reported in nodules or plaques which brings up the interesting question as to whether cutaneous eosinophilic granuloma is related to eosinophilic granuloma in the lung and other organs That brings up a possible relation to Christian's disease I believe that all of these diseases are part of the same toxic process and that this occurs as a fatal type and the Christian type occurs as a more benign disease Cutaneous eosinophilic granuloma and eosinophilic granuloma of the bone are part of the same process Last April, at the meeting in Detroit, Dr Curtis showed a patient with eosinophilic granuloma of the bone with cutaneous lesions

DR A C CURTIS, Ann Arbor Experience in 1 case does not make one an authority The patient that Dr Laymon mentioned had plaquelike lesions on the vulva and one lesion on the scalp, with a destructive process in the bone of the mastoid and in the crest of the ilium The lesions were plaquelike and very red Our attention was called to them because of the redness They promptly disappeared with a minimal amount of low voltage roentgen rays, as did the destructive lesions in the bone As I looked through the records to see whether any studies had been made, it occurred to me that this might be a disseminated sporotrichosis

DR STEPHEN ROTHMAN The diagnosis of eosinophilic granuloma was first suggested by our pathologist, Dr E M Humphreys I realize that these cutaneous lesions have not been reported in the literature It does not agree with any description published in the literature It reminded me of Niemann-Pick's disease, but the pathologist said that it was not Clinically it was typical scrofuloderma Extensive examinations were made for fungi The patient was seen in several departments I think that we can by now exclude tuberculosis and mycosis

Calcinosis of the Elbows Presented by DR DAVID V OMENS and (by invitation) DR HAROLD D OMENS

Leukoplakia, Sublingual (White Sponge Nevus?) Presented by MAURICE OPPENHEIM and (by invitation) DR WILLIAM A YACULLO

Pityriasis Rubra Pilaris in a Five Year Old Presented by DR MARCUS R CARO and (by invitation) DR LAURENCE L PALITZ

Parapsoriasis Guttata, with Unusually Small Lesions Presented by DR EDWARD A OLIVER and (by invitation) DR E LORANT and DR A B HENNINGSEN

A Case for Diagnosis (Psoriasis? Lupus Erythematosus?) Presented by DR ALBERT H SLEPYAN (by invitation)

DISCUSSION

DR S J ZAKON About two weeks ago I saw a man with carcinoma of the penis which had been treated for syphilis for some time I reviewed the literature, which is mostly in the field of urology (Melicow, M M, and Ganem, E J Cancerous and Precancerous Lesions of the Penis, *J of Urol* **55** 486, 1946) Early diagnosis is advised because of the serious prognosis It is interesting that there has never been a report of a case of carcinoma of the penis in a Jew, not because of any racial immunity but because of early circumcision In the Mohammedans, who circumcise their children at the age of 13, there is a definite incidence of carcinoma of the penis With early diagnosis some patients will recover In the far advanced case, even with radical amputation and removal of the regional glands, the prognosis is poor

DR THEODORE CORNBLUTH In a recent communication of *Science* (**105** 391 [April 11] 1947), Plant and Kahn-Speyer mention that carcinoma of the penis does not occur in persons who have been circumcised in the first few weeks of life and is rare in those who have been circumcised in childhood or in early puberty This induced them to study the carcinogenic action of smegma in mice using material obtained from horses Their work was evidently done carefully with suitable controls and showed that smegma is carcinogenic

This man's lesion was not highly characteristic for carcinoma of the penis, though that diagnosis is probably correct Epitheliomas at this site are usually of the squamous cell type and highly malignant Yet the present lesion began four years ago and the regional lymph glands are not enlarged

DR HAMILTON MONTGOMERY, Rochester, Minn I do not believe that this is an epithelioma histologically There are well defined pearls but few mitotic figures The cells are edematous and large, and there is an area of parakeratosis I think that this is a condyloma acuminatum and not an epithelioma As brought out by the first discusser, epithelioma of the penis usually grows rapidly except those that start on the foreskin In cases in which there is a so-called precancerous stage, moist leukoplakia or erythroplasia, simple circumcision is often enough to prevent the lesion from becoming a frank epithelioma I do not believe that in this patient amputation of the penis will be necessary

DR STURE JOHNSON, Madison, Wis (by invitation) I wonder whether the disease might be histoplasmosis At Ann Arbor, Mich, I saw 2 patients with lesions of histoplasmosis of the genitalia By careful search my co-workers and I were able to demonstrate the organisms in the tissues Schaeffer and his group have also reported cases in which the lesions were present on the genitalia Genital involvement with Histoplasma capsulatum is not unusual The organisms are usually difficult to detect in tissue and to culture I should like to call attention to two articles with photographs of genital histoplasmosis one by Palmer, Almolsch and Shaffer (ARCH DERMAT & SYPH **45** 919 [May] 1942) and the other by Curtis and Cawley (*J Urol* **57** 781 [April] 1947)

DR MAURICE OPPENHEIM (by invitation) The site of this epithelioma is unusual It is not the favorite place The favorite site for carcinoma of the penis is on the inside and on the glans The striking thing is that it has taken four years for it to grow to this size

I do not agree with Dr Montgomery that the histologic observations are atypical with few mitotic figures There is a decided inflammatory reaction surrounding the atypical epithelial growth This carcinoma looks like the so-called mule-spinner cancer, which is produced by lubrication oil used in cotton mills in England and Scotland

Necrobiosis Lipoidica Diabeticorum, Lesions on the Legs Presented by Dr S Rothman and (by invitation) Dr Z Felsher and Dr L Rubin

Linear Scleroderma Presented by Dr S Rothman and (by invitation) Dr H Krysa

Nevus Unius Lateris with Chronic Inflammation? Presented by Dr S Rothman and (by invitation) Dr E L Laden

Marcus R Caro, M D, *President*

Leonard F Weber, M D, *Secretary*

March 19, 1947

Lichen Sclerosus et Atrophicus and Rosacea with Acne and Rhinophyma in a 49 Year Old Woman Presented by Dr D Omens and (by invitation) Dr H Omens and Dr J Graffin

Lichen Simplex Chronicus of the Vulva of Three Years' Duration in a Seven Year Old White Girl Presented by Dr David V Omens and (by invitation) Dr H Omens and Dr N L Baker

Mycosis Fungoides d'Emblée Presented by Dr D Omens and (by invitation) Dr H Omens and Dr N L Baker

Widespread Cutaneous Nodular Sarcoidosis with No Systemic Manifestations Presented by Dr H Rattner and (by invitation) Dr Rodin and Dr J Graffin

Classic Acrodermatitis Chronica Atrophicans with Involvement of the Palms, Atrophy, Pseudosclerodermatous Plaques and Fibromas Presented by Dr M Ebert and (by invitation) Dr V Leaf and Dr J Graffin

Generalized Argyria from the Ingestion of Argyrol, One Ounce a Week for Five Years, to Prevent "Colds" Presented by Dr M Ebert and (by invitation) Dr J Graffin

Bizarre Pigmentation, Cause Undetermined in a Pituitary Type Dwarf Presented by Dr T Cornbleet and (by invitation) Dr D Cohen and Dr N L Baker

Against the diagnosis of condyloma acuminatum are the hard consistency, the broad base and the smooth surface The unusual factor is that these cancers are of long duration without metastases to lymph nodes

Epidermodysplasia Verruciformis Presented by DR MARCUS R CARO and (by invitation) DR LAURENCE L PALITZ

B G, a white girl aged 16, first had cutaneous lesions on the wrists and ankles at the age of 10, with gradual extension to the present distribution There was some improvement each summer, but the lesions never disappeared, there were no subjective symptoms There was no history of parental consanguinity

On the dorsal surface of the hands are patches of erythematous, raised papules with verrucous surfaces On the left hand these papules extend across the outer side of the thumb to involve the volar surface of the thumb for a short distance On both hands they extend around the ulnar side of the wrists to the flexor surface and then along the ulnar part of the flexor surface of the forearms to the cubital fossae There is a diffuse patch of erythematous and slightly hyperkeratotic dermatitis about the right axilla and also on the inner surface of the right arm There are also difluse lichenified patches on the outer surface of the hips, more on the right side, and on the outer surface of the right knee, while on the front of the left knee are many small warty papules On both insteps are many pea-sized, warty papules, which extend upward to the dorsal surface of the feet, across both ankles and along the outer side of the feet A few papules are present on the dorsal surface of several toes The skin is erythematous about the papules on the feet and ankles There is also diffuse acne on the forehead, which has improved with the use of 30 per cent sulfur paste The verrucous lesions have remained unchanged with local treatment and the administration of vitamin A and paraaminobenzoic acid

Histologic examination of a biopsy specimen from the left wrist showed a thick scale in which the cornified layers were interlaced Nuclei were absent except in one small area of parakeratosis The epidermis showed irregular acanthosis except for thinning beneath the parakeratotic scale At this site the granular layer was missing Elsewhere the granular layer was thickened, and in some cells there were small vacuoles The corium was edematous, and it contained a diffuse infiltration of lymphocytes, histiocytes and connective tissue cells In many places the edema and cellular infiltrate extended up into the epidermis, and the demarcation between the epidermis and corium became indistinct The Weigert stain showed the elastic fibers to be entirely missing from the upper part of the corium

DISCUSSION

DR HAMILTON MONTGOMERY, Rochester, Minn I would agree that this is an epidermodysplasia verruciformis clinically, but the histopathologic picture shows none of the features of this disorder, especially there is no evidence of vacuolization of the cells in the granular layer This histologic picture is more that of acrokeratosis of Hopf Histologically one might regard the condition also as a form of delayed epithelial nevus, using this term in the broadest sense

DR. MARCUS R CARO I think that clinically this case fits in essentially with the description of the disease in the literature Histologically it must be granted that there is here less vacuolization in the granular layer than has been described I recall also that in a patient shown before this society by Dr Weber (ARCH DERMAT & SYPH **49** 217, 1944) there was some variation from the classic picture I wonder whether we are not trying to classify the disease in these cases

dermatologic service the patient should be isolated I am sure that I have seen the infection carried by and transferred by attendants

Tuberculosis Colliquativa of the Sternum in an Eleven Year Old Negro Girl Presented by DR D V OMENS and (by invitation) DR H OMENS and DR B YAFFEE

Generalized Acne Scrofulosorum, Ecthyma Presented by DR F E SENEAR and STAFF

R S, a 4 year old Negro boy, was admitted to the Illinois Research and Educational Hospitals for the treatment of tuberculosis of the right hip For six months a generalized eruption had been present and large ulcerations had appeared on both legs

Examination revealed numerous folliculopapular lesions distributed over the entire cutaneous surface but most concentrated on the extensor surfaces of the extremities A few lesions exhibited central necrosis, older lesions were represented by slightly depressed scars, depigmented at the centers and with hyperpigmented borders A fading eruption of tiny lichenoid papules was present on the sides of the trunk Large granulating ulcers were noted over the anterior aspects of both legs

A bullous reaction developed after skin testing with 1 10,000 old tuberculin The report of biopsy is not yet available

DISCUSSION

DR H E MICHELSON, Minneapolis It has never been clear to me why certain types of tuberculosis respond to roentgen therapy and others do not For example, bone and most skin lesions do not respond while glandular tuberculosis and certain peritoneal types do There are many other facts about glandular tuberculosis that are most interesting, especially the seasonal incidence One does not see many patients with generalized tuberculous eruptions Recently Schmidt wrote a good article on these eruptions in the German dermatology journal (*Archiv für Dermatologie und Syphilis*)

Dermatitis in Red Area of Tattoo, Reaction Positive to Patch Test with Ammoniated Mercury, Negative with Cinnabar Presented by (by invitation) DR EVERETT T DUNCAN and DR CLARK F JOHNSON

Psoriasis Verrucosa, Arthropathy and Koebner's Phenomenon Presented by DR S ROTHMAN and (by invitation) DR J MCCREARY

DISCUSSION

DR MARY S SHERMAN It is variously estimated that 2 to 4 per cent of patients with symptoms of chronic arthritis have psoriasis Conversely up to 12 per cent of patients with psoriasis may be expected to have joint symptoms at one time or another Since the joints are rarely involved severely enough so that operation is indicated, reports of the pathologic changes are few

The clinical characteristics of so-called psoriatic arthritis are well known Males are affected more than females Although any joint or combination of joints may be involved, the joints most commonly and characteristically troublesome are the terminal interphalangeal joints of fingers and toes, and there are usually associated typical nail changes It is especially noteworthy that the joint

manifestations do not respond to treatment directed toward the arthritis, but improve miraculously as the cutaneous lesions subside

As a rule, therefore, the arthritic manifestations subside between exacerbations of the cutaneous lesions and in the intervals there are usually no symptoms of permanent residual damage Occasionally the joints are irritated sufficiently so that they do not return to normal, and there have been reports of complete ankylosis

In the present case arthritic symptoms appeared at the early age of 17, one and a half years after the onset of the cutaneous disease The psoriasis was essentially untreated and grew progressively worse During the next two and a half years, more and more joints became involved, and none of them improved The patient had been completly incapacitated by the pain in his knees

The roentgenograms of this boy's knees show little other than regional atrophy and beginning degenerative changes The cartilage space is well preserved, but there is irregularity of the articulating surface of the patella and small osteophytes forming at its periphery The roentgenograms of the hands show more typical changes In the right hand the terminal two joints of the fifth finger have been largely destroyed and marginal absorption of the ends of the phalanges is evident. In the left hand similar changes are observed in the terminal joint of the long finger and in all the joints of the index finger In the metacarpophalangeal joint there has been peripheral destruction of the articular cortex, so that only the central portion is visible

When biopsy of the right knee joint was undertaken, the cutaneous lesions had begun to show some improvement Exploration of the knee joint revealed gross damage There was severe synovitis which had resulted in dense adhesions The synovial membrane had grown over the joint surfaces, so that the tibia was scarcely visible The patella was encircled by numerous osteophytes and its articular cartilage was completely destroyed except for a few soft gelatinous remnants What was visible of the surfaces of the tibia and femur appeared to be normal This first section is from the synovial membrane It shows the grossly hypertrophied villi The most striking change is the great amount of well organized, vascular, fibrous thickening, with relatively few signs of inflammation, an observation which was noted by Bauer and his associates The blood vessels are also somewhat sclerotic This is in contrast to the chronic inflammatory character of this synovial membrane taken from a patient with Still's rheumatoid arthritis

A piece of bone and cartilage was removed from the edge of the femoral condyle in an area where the articulating surface looked normal, but the section reveals advanced changes No articular cartilage remains It has been entirely replaced by a collagenous type of fibrocartilage which contains numerous blood vessels Beneath the cortex is seen a sort of chronic granulation tissue Between these two the bony cortex has been thinned to a narrow plate, which in one spot is almost disrupted

It is, of course, not possible to say whether these changes are characteristic of psoriasis They are certainly not like those one associates with rheumatoid arthritis In fact, they are not quite like any of the known chronic arthritides It will take further study before we understand how this appearance is produced and what it means

Psoriasis Verrucosa, Developing During Treatment Presented by DR S ROTHMAN and (by invitation) DR L RUBIN

DISCUSSION

DR STEPHEN ROTHMAN The relationship between psoriasis and arthropathia according to Julius Bauer is due to debility of conjugated genes He published

on the basis of criteria that are a little bit too rigid I think that the lesions in all of these cases are forms of tardy epithelial nevi

A Case for Diagnosis Presented by DR FRANCIS E SENEAR

M S, a woman aged 75, was seen with an eruption on the arms and legs which had been present constantly for the past five years, without any appreciable change except for extension in recent years There are no symptoms The patient states that she was seen at the Billings Clinic some years ago and that a diagnosis of purpura was made She has been seen by a number of other physicians, and a variety of diagnoses have been suggested

Biopsy shows a slight degree of intracellular edema of the epidermis with liquefaction degeneration of the basal layer in several places At these sites the blood vessels were dilated and were surrounded by a loose infiltrate of lymphocytes and erythrocytes, some of the cells extending up to the basal layer Perl's prussian blue reaction did not show any iron pigment

A Case for Diagnosis (Idiopathic Multiple Hemorrhagic Sarcoma [Kaposi] or Pigmented Purpuric Lichenoid Dermatitis?) Presented by DR O H FOERSTER and DR H R FOERSTER and (by invitation) DR D M RUCH

V S, a man aged 28, is presented because of an eruption on his lower legs, feet and toes of three years' duration He stated that in 1944 the dorsal and lateral surfaces of his great toes showed a red-brown discoloration and elevated lesions The condition remained localized until January 1946, when it extended to the dorsal surfaces of his feet and toes and to the lateral surface of each ankle In June an apparent ulceration appeared on each side of his right ankle These open lesions healed in October 1946 The eruption was first observed on his lower legs in November 1946

Examination discloses a red-brown lichenoid, diffuse, small papular eruption in patches on the sides of the first three toes of the left foot and the first four toes on the right foot, the dorsal surfaces of the feet, at the bases of the toes the heels, ankles and the anterior and medial surfaces of the lower legs directly above the ankles

The result of the Rumple-Leeds test was negative Intradermal and subcutaneous tests with congo red elicited negative reactions for amyloid

The examination of the blood showed erythrocytes 6,530,000, leukocytes 12,750 hemoglobin over 18 Gm, thrombocytes 350,000, clot retraction time 1 hour and 20 minutes, coagulation time 10 minutes and 30 seconds and bleeding time 3 minutes and 30 seconds

The histologic examination of a section taken from the dorsal surface of the right foot adjacent to the toes showed moderate hyperkeratosis and a normal epidermis There was proliferation of the walls of all the vessels of the cutis A moderately dense lymphocytic infiltrate was present in the upper and middle parts of the cutis The iron stain showed a large amount of hemosiderin in the cutis

DISCUSSION

DR HAMILTON MONTGOMERY, Rochester, Minn In Foerster's case, it was difficult to make a histologic diagnosis The section showed proliferation of capillaries and some of the smaller venules Some of the capillaries were open ended, as one sees in Kaposi's sarcoma There were also apparently some lymphocytoid cells of Marchand Against a diagnosis of Kaposi's sarcoma was the diffuse uni-

sarcoidosis, much as Dr Rothman presented today, where there was involvement of bone, lymph glands and skin We have studied the cases extensively by biopsy, chemical studies and roentgenogram In this series, to be presented before the Society of Investigative Dermatology, many showed striking improvement with vitamin D_2 and dihydrotachysterol therapy

DR STEPHEN ROTHMAN I agree with Dr Curtis that sarcoid structure has a multiple etiology, sarcoid leprosy, sarcoid syphilis and foreign-body sarcoids being important examples Still, there is a rather well defined entity of "sarcoidosis" with characteristic involvement of skin, bone, eyes and lungs, and evidence is accumulating that this disease is of tuberculous origin The "positive anergy" to tuberculin and the tuberculin-neutralizing properties of the blood serum are present in such high percentage in our material that it must be regarded as highly characteristic for this condition

DR ARTHUR C CURTIS I did not intend to leave the impression that sarcoidosis is not a clinical entity I think that it is Nor did I mean that silica or a foreign body reaction is a common cause of sarcoidosis There are some cases in which it may be the etiologic factor

Familial Keratosis Pilaris with Monilethrix-like Anomaly of the Hair in Fourth Generation, Maternal Side Presented by DR S ROTHMAN and (by invitation) DR R J STANWOOD

Dermatitis Herpetiformis Potentiated Effect of Pyribenzamine-Sulfapyridine Combination Presented by DR S ROTHMAN and (by invitation) DR J H MCCREARY

DISCUSSION

DR STEPHEN ROTHMAN In this case tripelennamine hydrochloride (pyribenzamine®) acts not because it is an antihistaminic drug, but because it contains the pyridine nucleus The therapeutic result in this case has been strikingly good

DR ZACHARY FELSHER (by invitation) There seems to be a relation, at least in some cases of dermatitis herpetiformis, between the presence of the pyridine group in the drug and its beneficial action In 2 of our cases of dermatitis herpetiformis both nicotinamide and pyridium® (phenylazo-alpha-diaminopyridine monohydrochloride) appeared beneficial Both drugs contain pyridine groups The disease in one of these cases was absolutely refractory to sulfapyridine, yet responded to nicotinamide and pyridium® In 2 other cases sulfapyridine caused complete clearing of the eruption, but nicotinamide and pyribenzamine® had no effect In a fifth case none of the pyridine-containing drugs worked at all I do not know the reasons for this discrepancy

In 1 of our cases of dermatitis herpetiformis which was completely controlled by sulfapyridine, 300 mg of paraaminobenzoic acid daily was given simultaneously to note whether this drug would interfere with the action of the sulfapyridine as it does in bacterial infections There was no interference with the beneficial action of the sulfapyridine Perhaps this points to the possibility that the action of sulfapyridine in dermatitis herpetiformis is different from its action in bacterial infections

DR ASHTON L WELSH, Cincinnati (by invitation) I did not see the patient under discussion, but I am interested in what has been said about the use of sulfapyridine in dermatitis herpetiformis In the last year my co-workers and I have treated a number of patients who had dermatitis herpetiformis with

form staining of the entire section with hemosiderin rather than a spotted deposition of hemosiderin There was no evidence of any tumor stage, such as fibrosarcoma I believe that this is probably an early stage of Kaposi's sarcoma both clinically and histologically One must bear in mind that Kaposi's sarcoma can progress slowly, just as mycosis fungoides may remain in an early plaque stage simulating parapsoriasis for a period of many years

DR STEPHEN ROTHMAN The patient presented by Dr Senear was seen in the University of Chicago Clinics by Dr Stenhouse and myself in 1943 At that time the tentative clinical diagnosis of Majocchi's disease with hypertension was made The biopsy specimen did not show extravasation of blood or blood pigment I believe that the eruption has not changed much in the last four years, and it is remarkable that the hypertension, too, is rather benign and stationary

Gottron in Germany stressed the point that Majocchi's purpura is always associated with either polycythemia or hypertension I do not know whether this has ever been confirmed, but the association of a widespread telangiectatic eruption with hypertension certainly is remarkable

DR F E SENEAR Several years ago I observed 2 cases, 1 patient was shown before this society and originally presented the somewhat mammalated appearance that this patient showed on the leg Histologically the lesions in both cases were typical of Kaposi's sarcoma

DR HARRY R FOERSTER, Milwaukee In our case we had considered the possibilities of Kaposi's idiopathic hemorrhagic sarcoma, amyloid disease and lichenoid pigmentary dermatosis and, on clinical grounds, decided in favor of the last named Dr Montgomery made a histologic diagnosis of Kaposi's sarcoma without having seen the patient MacKee and Cipollaro reported a case of Kaposi's sarcoma in which only inflammatory manifestations were present, which is in accord with Dr Webster's comment I am inclined to agree with him Our patient observed his first lesions three years ago These lesions were confined to the feet, particularly the dorsa of the toes, for almost three years In January 1946, the eruption extended to the dorsum of each foot and to the ankles, and during the last five or six months lesions have appeared on the legs Today he shows lesions that have developed since our first examination of him six weeks ago These lesions are more of a purpuric type The dark red in this case contrasts with the orange in Dr Caro's case, which I thought was an example of Schamberg's disease In Schamberg's or Majocchi's disease I have not seen the papular infiltrate exhibited by our patient, nor have I seen a case of Kaposi's sarcoma with so little infiltration I therefore favored a diagnosis of pigmented purpuric lichenoid dermatitis

Extensive Morphea Presented by DR S ROTHMAN and (by invitation) DR L RUBIN

Eosinophilic Granuloma Progress with High Voltage Roentgen Therapy Presented (by invitation) by DR M PIERCE and DR S ROTHMAN

Since this patient was presented originally at the Chicago Dermatological Society, in February 1947, further search for a positive agent in cultures from biopsy specimens, inoculation into guinea pigs and on bacteriologic mediums have failed to reveal the presence of an organism

On February 28, a biopsy of the skull lesion in the right parietal bone was made The histologic picture of this lesion was similar to that found in the granulomatous lymph node tissue The microscopic report was as follows The

sulfapyridine Several interesting observations have been made Apparently large amounts of sulfapyridine are usually unnecessary to control the reaction if pyribenzamine® is given simultaneously The 4 to 7 tablets of sulfapyridine daily can often be reduced to 1 tablet a day if pyribenzamine® is given at the same time It was our experience that pyribenzamine® alone has not been very helpful It has not been helpful in preventing the outcropping of skin lesions Another group of 10 patients who had dermatitis herpetiformis were treated with sulfapyridine and paraaminobenzoic acid simultaneously They were given as much as 100 mg of paraaminobenzoic acid daily We observed in only 2 of these 10 patients some inhibition of the action of the sulfapyridine In the other 8 there was no apparent inhibition of this action It appears that in dermatitis herpetiformis sulfapyridine has some action on the causative bacteria which is different from the action usually attributed to this drug on the bacteria involved in other diseases The paraaminobenzoic acid alone may have some favorable action in dermatitis herpetiformis, but to date we have not treated patients who had dermatitis herpetiformis with this drug alone This should and will be done to control the study already mentioned Suggesting some unusual action of the sulfapyridine on the bacteria in dermatitis herpetiformis is the fact that in many instances only 1 tablet daily, or 1 every other day, was necessary to control this problem This has not been an observation with this drug in other diseases

DR. ADOLPH ROSTENBERG JR (by invitation) I could not make a diagnosis of dermatitis herpetiformis In order to evaluate the therapeutic result one should be sure of the diagnosis I do not know that it was a papular eczema It started eight years ago

DR STEPHEN ROTHMAN Many of the outstanding New York dermatologists who saw this patient did not diagnose dermatitis herpetiformis because the patient displayed no vesicles However, after we had done a patch test with potassium iodide, the patient had a rather characteristic vesicular eruption Dr O'Leary saw the patient at that time and agreed with the diagnosis of dermatitis herpetiformis A few characteristic grouped vesicular lesions are still present

Kaposi's Sarcoma in a 50 Year Old White Man with Tumors on the Toes Presented by DR EDWARD A OLIVER and Dermatology Staff

A Case for Diagnosis (Exfoliative Dermatitis or Pityriasis Rubra Pilaris?) Presented by DR JULIUS E GINSBURG and (by invitation) DR I EIRINBERG

A Case for Diagnosis (Glossy Skin? Morvan's Disease? Possible Radio Dermatitis?) Presented by DR JAMES HERBERT MITCHELL and (by invitation) DR ROBERT H HARRIS

Generalized Mycosis Fungoides of Six Years' Duration Presented by DR EDWARD A OLIVER and Dermatology Staff

Acrodermatitis Chronica Atrophicans Presented by DR I M FELSHER and DR A SLEPYAN and (by invitation) DR I EIRINBERG

Alopecia Areata Totalis Associated with Hypothyroidism, Regrowth of Hairs Presented by DR S ROTHMAN and (by invitation) DR Z FELSHER and DR L RUBIN

tissue fragments were made up for the most part of large acidophilic or nonfoamy macrophages These had large irregular-shaped nuclei with indistinct nucleoli They contained a moderate amount of cytoplasm Many of these macrophages were binucleated, and there was some infolding of the nuclear membrane Scattered among these cells were a moderate number of eosinophils, more numerous in some of the fragments There were also a few smaller cells with dark nuclei, which presumably were lymphocytes There were a few multinucleated giant cells, some of these containing vacuoles or slitlike spaces A stain for fat (sudan IV) revealed that a moderate number of the macrophages contained small or moderate-sized fat droplets, or lipoprotein granules, most of which were not anisotropic Blood lipid studies showed no elevation of the total blood lipids or blood cholesterols

Therapy consisted of external irradiation, massage and physical therapy to correct the fibrosis in the cervical region Before admission to Bobs Roberts Hospital, the child had received a total of 2,593 r between Jan 13, 1939 and June 12, 1945 Since June 14, she has received forty-three treatments to seventeen cutaneous lesions, totaling 1500 r with single doses of 300 to 500 r She has experienced no radiation sickness She improved progressively The lesions are gradually regressing, and at present there are no discharging areas She has gained 27 to 30 Kg in weight since admission The retraction of her head has improved to some degree The patient is now to be discharged from the hospital and will be followed in the outpatient department

Eosinophilic Granuloma Presented by DR EDWARD A OLIVER and (by invitation) DR E LORANT

M E C, a white man aged 42, was presented at the March meeting He is presented today to show the effect of treatment

DISCUSSION

DR H M BULEY, Champaign, Ill (by invitation) These 2 cases illustrate again that there are various etiologic entities in eosinophilic granuloma In both cases there is symptomatic involvement which would not be present in many other cases The improvement following roentgen ray treatment is remarkable In the case I observed roentgen rays had no effect I saw the patient two weeks ago, and the lesions were practically as I saw them two years ago

DR ASHTON L WELSH, Cincinnati (by invitation) I wish to report further on the patient that my co-workers and I observed in Cincinnati, who was treated in the same fashion as this one His improvement was as striking as was the improvement in Dr Oliver's patient He now has fewer lesions, has gained weight and is considerably improved His spleen, which was palpable before roentgen therapy was begun, is still palpable but decidedly smaller The few small palpable lymph nodes that he had before roentgen therapy are still palpable and have been only slightly reduced in size They were chiefly around the neck and in one axilla We have been carefully watching this man, and I cannot help feeling that this syndrome is a little different from other forms of lymphoblastoma, if it is a lymphoblastoma, particularly in that the toxic or "id" reactions in this syndrome are so pronounced Low voltage roentgen rays administered to various skin areas in the man we treated produced little change, as in Dr Oliver's case

DR HAMILTON MONTGOMERY, Rochester, Minn Eosinophilic granulomas of the skin should be differentiated from eosinophilic granulomas of the skin and bone A series of articles appeared in the February 1947 issue of THE ARCHIVES Eosinophilic granuloma of the skin may be of various types, including pseudo

Chronic Discoid Lupus Erythematosus—Persistent Despite Treatment for Thirty-Four Years Presented by DR JAMES R WEBSTER, DR SAMUEL BLUEFARB and (by invitation) DR J GRAFFIN

Scleroderma Presented by DR DAVID V OMENS and (by invitation) DR B YAFFE and DR HAROLD D OMENS

A Case for Diagnosis (Granuloma Telangiectaticum?) Presented by DR THEODORE CORNBLEET and (by invitation) DR H SCHORR and DR B YAFFE

Hodgkin's or lymphoblastoma type and the type described by Lewis, which seemed to be on an allergic basis and simulated changes seen in periarteritis nodosa In the case of eosinophilic granuloma of the bone reported by Curtis there were elevated granulomatous cutaneous lesions I saw a patient today with ulcerative lesions with decided changes in the bones of the skull which makes the disease in this case similar to Hand-Schuller-Christian's disease and Letterer-Siwe's disease My co-workers and I have observed a patient with multiple small granulomatous lesions with similar cystic lesions and rarefaction in the bones In another case in which our original diagnosis was histiocytoma, there were multiple small nodular lesions in the skin resembling xanthoma and bony lesions subsequently developed in the mandible Farber of Boston groups eosinophilic granuloma of the skin, Letterer-Siwe's disease and Hand-Schuller-Christian's disease together as variants of the same process and regards any evidence of deposition of fat in the tissue as a secondary degenerative phenomenon He therefore would differentiate these conditions from xanthomatosis and diseases of lipid metabolism Some years ago, however, Weidman reported a case of xanthoma disseminatum in association with Hand-Schuller-Christian's disease, and there are other such cases in the literature so that the exact classification of eosinophilic granuloma of the bone and skin remains to be determined

Noduloulcerative Syphilid of the Chest Wall Presented by Dr Herbert Rattner and (by invitation) Dr H Rodin and Dr N L Baker

Ulceronodular Syphilis of the Abdomen Presented by Dr James R Webster and (by invitation) Dr J Graffin

A Case for Diagnosis (Pyoderma Faciale?) Presented by Dr Theodore Cornbleet and (by invitation) Dr D Cohen and Dr J Graffin

Leonard F Weber, M D, *Secretary*

June 18, 1947

Adenoma Sebaceum Presented by DR T CORNBLEET and (by invitation) DR H SCHORR and DR J GRAFFIN

R S, a Negro woman aged 23, as a child had frequent episodes of "spasms" which may have been epileptic-like in nature She finished the seventh grade in school at the age of 19 years, and she works as a dishwasher

On May 22, 1947, she entered a medical ward at Cook County Hospital with acute rheumatic fever Subsequently, she had a spontaneous pneumothorax, which is gradually disappearing

Examination reveals an eruption limited to the face which is predominantly on the central portion, chin and eyelids The lesions consist of dark brown papular nodules varying from a few millimeters to 1 cm Neurologic examination revealed no abnormalities Fundoscopic examination has not yet been completed

The Kahn reaction of the blood was negative Urinalysis showed albumin (1 plus) The examination of the blood showed hemoglobin 66 per cent, erythrocytes 3,530,000, leukocytes 5,600, with a normal differential count, and nonprotein nitrogen 22 mg per hundred cubic centimeters The sedimentation rate was 40 mm per hour

The roentgenogram of the chest originally showed a left total pneumothorax, at present there is a 30 per cent residue The roentgenogram of the ankles showed no abnormalities The histologic section from a nodule of the cheek is presented

DISCUSSION

DR M R CARO I agree with the diagnosis both clinically and histologically Histologic examination showed a fibromatous type of tumor rather than hyperplasia of sebaceous glands

DR ROBERT M B MACKENNA, London, England (by invitation) It was clearly shown in this case that the lesions are not present to any great degree

Parapsoriasis Guttata (Pityriasis Lichenoides Chronica) Presented by DR STEPHEN ROTHMAN and (by invitation) DR Z FELSHER and DR R SNAPP

Pityriasis Lichenoides Chronic Varioliformis Presented (by invitation) by DR MAURICE OPPENHEIM and DR W A YACULLO

May 21, 1947

A Case for Diagnosis (Erythrasma?). Presented by DR T CORNBLEET and (by invitation) DR H SCHORR and DR J GRAFFIN

Granuloma Inguinale Treated with Streptomycin Presented by DR M H EBERT and (by invitation) DR N BAKER

O N, a Negro aged 46, has been ill for fifteen years He has been a bed patient in the Cook County Hospital for the past twenty-eight months He was admitted in January 1945 with extensive ulceration of the inguinal areas, scrotum and perineum Smears of these areas showed Donovan bodies From July 1946 to February 1947 he was treated with podophyllum solution (20 per cent in liquid petrolatum) with some improvement On April 18 treatment with streptomycin was begun and given for one month, 120,000 units every three hours The process on the inguinal areas and scrotum has healed, on the perineum there is still a small ulcer (3 by 5 cm)

on the upper lid Epithelioma adenoides often attacks the upper lid, and adenoma sebaceum spares it

Contrast Sweating Above and Below Line of Paraplegia Presented by Dr T Cornbleet, Dr H Schorr and Dr N L Baker

H C, a Negro aged 25, was a patient at the Hines veterans' hospital from March 6, 1946 to January 1947 He complained of pain in the right leg and in the lower thoracic part of the spine, of four years' duration A laminectomy was done May 26, 1946, and a lesion was encountered at the level of the ninth thoracic vertebra which appeared to be an intramedullary cord tumor He was transferred to the Cook County Hospital Jan 20, 1947, where he complained of profuse sweating of the entire upper half of the body Injections of atropine sulfate afforded relief for two to three hours

Physical examination showed complete flaccid paralysis of the lower extremities Pain and pressure sense are diminished on the lower part of the abdomen and lower extremities There is no profuse sweating of the face, neck, upper extremities or trunk There are follicular keratoses of the sternum and other areas on the trunk

The urine contained albumin (1 plus) and many white blood cells The Kahn reaction of the blood was negative, and the blood cell count was normal The spinal fluid contained 330 cells per cubic millimeter, and the protein was 3,500 mg per hundred cubic centimeters

A roentgenogram taken after injection of opaque material indicated a complete block at the level of the ninth thoracic vertebra

DISCUSSION

Dr Stephen Rothman This is a good example of hyperhidrosis of organic central nervous system origin On the patient's back there are beginning signs of prickly heat, showing that softening of the horny layer and plugging of the pores occur in hyperhidrosis irrespective of whether it is peripheral or central in origin

Dr Theodore Cornbleet The patient presents all the changes in some areas that have been described for miliaria induced by heat Above the point of laminectomy and paraplegia there is excessive sweating, below there is excessive dryness The plugging of sweat pores and the changes that follow in miliaria are here reduplicated Thus it is excessive sweating itself which leads to cornification at the sweat duct orifices Heat is not necessary for the production of the syndrome, except in so far as it stimulates increased sweating

A Case for Diagnosis (Seborrheic Dermatitis) Presented by Dr Theodore Cornbleet and (by invitation) Dr D Cohen and Dr N L Baker

Cutaneous Blastomycosis, Therapeutic Result Presented by Dr F E Senear and staff

W S C, aged 57, was referred to the Department of Dermatology, Illinois Research and Educational Hospitals, in October 1946 with the diagnosis of blastomycosis, proved by biopsy Examination revealed an irregularly circinate plaque at the left commissure of the mouth, extending laterally on the cheek for about 8 cm The lesion was sharply marginated and had a precipitous border and a mammillated, somewhat elevated, crusted surface A few microabscesses were visible in the border, and the central portion of the lesion had healed, leaving a fine pinkish scar

DISCUSSION

DR ROBERT BARTON, Dubuque, Iowa (by invitation) Since 1946 at the Chicago Intensive Treatment Center 9 patients with granuloma inguinale have been treated with streptomycin In every case the lesions disappeared within forty-five days after treatment was instituted In 3 of the cases there have been relapses Streptomycin as my co-workers and I have used it may or may not cure granuloma inguinale, but to date it is the most effective drug for that disease The pattern in Dr Ebert's case conforms to that in ours After treatment was stopped the lesions continued to heal without additional therapy The patients returned perhaps a month or two later with the lesions completely gone It appears that once treatment is given, the effects are protracted

Werner's Syndrome (Progeria of Adults) Presented by DR T CORNBLEET and (by invitation) DR D COHEN and DR J GRAFFIN

Pigmented Purpuric Lichenoid Dermatitis Presented by DR T CORNBLEET and (by invitation) DR D COHEN and DR N L BAKER

T B, a white man aged 30, has had purplish spots on the legs and dorsum of the feet for two years These are asymptomatic In January 1945 the right testis and epididymis were removed because of tuberculosis

On both legs, mainly on the anterior aspect, there are lichenoid purpuric papules Similar lesions are present on the dorsa of the feet, in groups There are pigmented macules, 2 to 5 mm in diameter, among the papules of the legs and dorsa of the feet

Roentgenogram of the chest reveals a soft fuzzy infiltration in the right apex Biopsy by Dr Caro showed Gougerot-Bloom's disease

DISCUSSION

DR H E MICHELSON, Minneapolis Pautrier said that if we wish to advance dermatology, it would be well if we eliminated ten names a year instead of adding ten new ones Following his suggestion, I would like to eliminate the name Gougerot-Bloom's disease now Sooner or later, we must decide that all of these diseases that are characterized by localized hemosiderosis are one and the same thing and differ only in their extent and their localization Gracing them with long names is one of the troubles that dermatology has had to contend with for many years

Scrofuloderma, Pott's Disease and Retrosternal Abscess Presented by DR T CORNBLEET and (by invitation) DR H SCHORR and DR N L BAKER

A Case for Diagnosis (von Recklinghausen's Disease?) Presented by DR I M FELSHER, DR JULIUS E GINSBERG, DR A SLEPYAN and (by invitation) DR I EIRINBERG

Mrs L P, a well nourished, well developed, Negro woman aged 49, was first seen at Mandel Clinic, Michael Reese Hospital, on May 15, 1947 On the left buttock and left thigh there are present two large, well circumscribed tumors measuring 4 5 by 3 inches (11 by 7 cm) and 7 by 3 inches (18 by 7 cm), respectively These tumors have been present since birth but have caused the patient no difficulty with the exception of occasional discomfort when pressure is applied

Roentgen irradiation, in a total dose of 2,085 r, has been administered, along with potassium iodide orally in a maximum daily dose of 90 minims (about 6 cc) The lesion has cleared except for four small crusted areas at the periphery

Blastomycosis Presented by DR EDWARD A OLIVER and DR J M MCCUSKEY

The patient is a dairy operator and handles powdered milk The lesions appeared about four weeks ago

At present there are twelve nodular lesions on the face and the back of the neck, varying in size from that of a split pea to that of a hazelnut The lesions are erythematous, boggy and studded with pinpoint to pinhead-sized yellow pustules, especially at the periphery On the right hand, there is a deep, erythematous, indurated mass, the size of a hen's egg

Microscopic examination of material from the periphery of the lesions showed Blastomyces

DISCUSSION OF PREVIOUS TWO CASES

DR OLIVER S ORMSBY Years ago, when we had foreign guests, it was possible within a short period to bring in several patients with blastomycosis for demonstration Such cases are now comparatively rare There was a time when I had 100 cultures grown from 100 different patients Dr MacKenna can get no idea about what blastomycosis looks like by seeing the patients presented today One patient was cured with efficient treatment, and the other did not have typical lesions The skin lesions in a typical case are classic They occur in plaques with elevated margins and a superficial smooth scar in the center The margin of the lesion slopes and contains true abscesses in which Blastomyces are found The cases of systemic disease are different My co-workers and I had the privilege of reporting the first one in 1903, in which the lesions were clinically and symptomatically blastomycosis The lesions in that case consisted of subcutaneous abscesses, ulcerations and nodules We proved that the skin lesions came by way of the circulation At that time a large number of patients with systemic blastomycosis died—at least 50 per cent of the patients with systemic disease died The course was like that of severe pellagra some years ago I was in London when the disease was being discussed in this country, and the London men were much interested It was not until 1907, when many physicians from abroad were here to attend the international congress, that we were able to demonstrate to our foreign guests that blastomycosis was an entity—they thought it was syphilis I am sorry that Dr MacKenna did not see an example of the American variety of the disease

DR STEPHEN ROTHMAN We will have the opportunity to demonstrate a case of extensive American blastomycosis to Dr MacKenna tomorrow in Billings Hospital Dr Senear's patient has shown remarkable response to therapy In cases with widespread lesions the initial therapeutic effect of iodides is always impressive, but it takes years for them to clear up The lesions heal rapidly in the center but spread peripherally The supporting effect of local roentgen irradiations is rather modest Local application of fungicides is ineffective, in spite of their fair fungicidal action on Blastomyces in vitro We have not seen any beneficial effect of vaccine therapy Apparently cases with small simple lesions are easier to manage

DR. M J REUTER, Milwaukee In Dr Senear's case there is still some activity around the borders of the lesions In resistant plaques such as this, I

The tumors are extremely flaccid, lobulated and pendulous The skin covering them appears lighter and atrophic and at the periphery of the lesions is filled with giant comedos On palpation the lesions are firm and nodular

Microscopic sections taken from the edge and center of the lesion show hyperkeratosis, deep brown pigmentation of the basal layer, flattening of the rete processes and some hyperplastic sebaceous glands containing comedos The corium is replaced by a tumor mass of connective tissue cells containing many small blood vessels There are numerous mast cells present With the Van Gieson stain, the tumor tissue is essentially the same color as that of normal collagen The orcein stain shows absence of elastic fibers throughout the tumor

Lesions on the buttock and thigh of patient with diagnosis of von Recklinghausen's disease

Granuloma Fungoides, D'emblée Presented by DR THEODORE CORNBLEET

F S K, a white man aged 74, presents mushrooming tumors on the right wrist and posterior hair line Near the scalp lesion and on the left ear lobe there are several infiltrated plaques that are sharply outlined and of various sizes There is itching The lesions appeared eight months ago There were no preceding lesions of any kind or any itching The patient was in the hospital about the time of onset of the skin changes

Mycosis Fungoides Treated with Sodium Paraaminobenzoic Acid Presented by DR JAMES H MITCHELL

Mrs L McC, aged 52, was first seen on Jan 18, 1945, with a huge exuding tumor on the left ramus of the jaw There had been a generalized pruritic eruption for the past two years Various lesions of the type on the left cheek had appeared and had healed spontaneously with scarring

A clinical diagnosis of mycosis fungoides was made and confirmed by biopsy Intensive roentgen ray treatment was given to the point of tolerance on various occasions with good immediate response Intramuscular injections of chaulmestrol were begun on Jan 28, 1947, which were followed by an intense generalized toxic eruption

have been destroying the lesion with diathermy, at the same time giving the patient large doses of potassium iodide by mouth

DR THEODORE CORNBLEET The surgeons think that the dermatologists' approach to the treatment of cutaneous blastomycosis with medical measures is inadequate, inefficient and a loss of time They believe, at least some of them, that the lesions should be excised and the defects grafted They believe that even large areas are better treated with such a direct attack Their view is that as long as the disease is superficial breadth of area involved is a secondary consideration

DR FRED BECKER, Duluth, Minn Some investigators have expressed the belief that, prior to iodide therapy for systemic blastomycosis, a cutaneous test with a Blastomyces vaccine should be performed If the result is positive, it denotes allergy and desensitization must be performed, with gradually increasing doses of the vaccine until this positive cutaneous sensitivity is eliminated Then only should iodine therapy be instituted They cited several cases in which giving iodides produced rather disastrous results in a patient highly sensitive to the vaccine

DR STEPHEN ROTHMAN I understood that vaccine was required as initial therapy in cases with hypersensitivity to iodides and that the vaccine therapy was supposed to desensitize to iodides I wonder whether these observations have been corroborated In our case with no iodide sensitivity, vaccine therapy had no effect whatsoever although the patient shows strongly positive cutaneous reactions to the vaccine

DR ADOLPH ROSTENBERG JR (by invitation) I have had no firsthand experience treating blastomycosis As I understand Conant and his colleagues, a patient with systemic involvement who is allergic to a blastomycosis vaccine may have a spread of the blastomycosis if he is given iodides If the vaccine is given first some kind of immunity develops, so that the patient is subsequently able to take iodides The present immunologic point of view regarding diseases such as blastomycosis has altered considerably Primarily through the work of Dr Rich at Johns Hopkins Hospital it has been realized that there is dissociation between so-called immune phases and the hypersensitive phases of a disease and not, as originally stated, that hypersensitivity is a way station on the road to immunity This makes it questionable whether anything is accomplished from the point of view of immunity by desensitization in the tuberculin type of sensitization Possibly one succeeds only in abolishing or reducing the skin reaction

DR F E SENEAR Dr Ormsby recommended that arsphenamine therapy be employed when patients who had been receiving iodides for blastomycosis failed to show further progress and that after this procedure, with the use of but a few injections, the blastomycosis would again become responsive to iodide therapy

While I believe that American blastomycosis is not seen as frequently now as in the past, there has been a change in the clinical appearance of this disorder My co-workers and I have recently seen several patients with cutaneous manifestations from systemic blastomycosis, and in these instances a considerable number of widely scattered lesions have developed spontaneously About three years ago, I had, in the space of four months, 3 patients in this category The organism is readily demonstrable in lesions of this type We have also seen in recent years a larger number of patients with the deep-seated furunculoid, or cold abscess, type of lesion

At the suggestion of Dr Arthur Curtis, treatment with sodium paraaminobenzoic acid was begun March 29, tablets, 2 Gm, were taken every three hours during the waking hours The clinical improvement has been spectacular

DISCUSSION OF TWO PRECEDING CASES

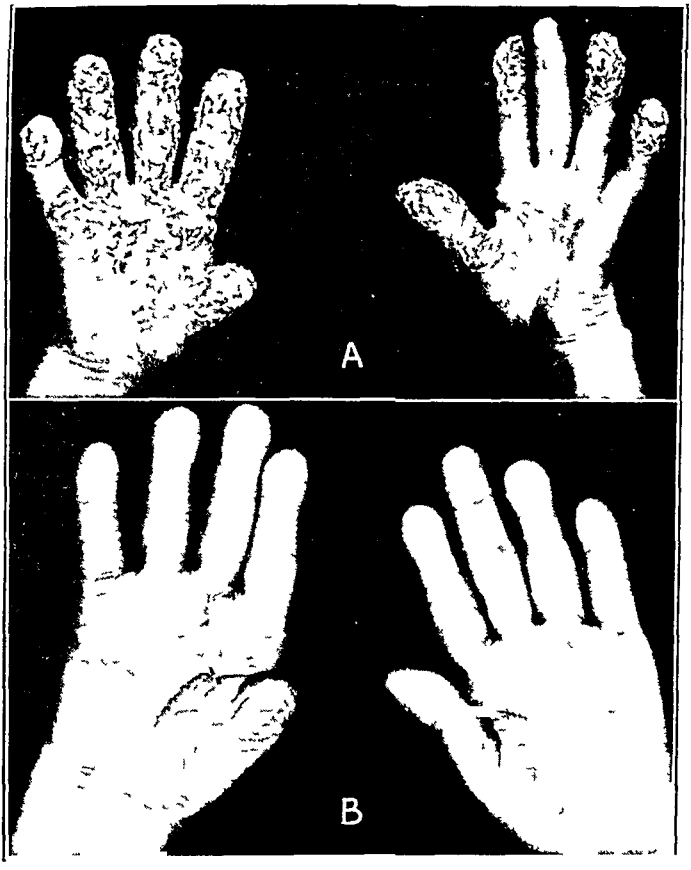
DR HAMILTON MONTGOMERY, Rochester, Minn With respect to Dr Mitchell's case, the photograph of the patient shows a definite reaction apparently to chaulmestrol which I have been using for some time in cases of mycosis fungoides but with, on the whole, indifferent results There have been 1 or 2 cases in which striking improvement occurred Dermatitis from the use of chaulmestrol is an unusual occurrence

DR A C CURTIS, Ann Arbor, Mich Two months ago, at the meeting here, Dr Mitchell asked whether I could suggest anything that might be of value in his 2 cases of mycosis fungoides In both cases the roentgen response had been exhausted I suggested that he might try para-aminobenzoic acid Dr Zarafonetis, a member of our medical department, and I have been using sodium para-aminobenzoate in the treatment of some of the lymphoblastomas Because of its relation to the local anesthetics we thought that it might have some value in certain of the lymphoblastomas Our patients received 2 Gm of the sodium salt every two hours around the clock Dr Mitchell gave 2 Gm of the acid every three hours around the clock Some of our patients had a Herxheimer reaction characterized by redness and burning of the lesions The reaction would subside, and often the lesions would disappear The first patient we treated was something like the one Dr Mitchell showed today, a woman with a psoriasiform type of mycosis fungoides The effect of roentgen rays had long been exhausted She also improved rapidly on treatment The drug is by no means innocuous It has many disadvantages when given in large doses One is that it produces glycosuria, which seems to be related to a lowering of the renal threshold because the patient often has blood sugar values that are relatively low, 40 or 50 mg per hundred cubic centimeters In 1 patient with psoriasis hypoglycemia of such severity occurred that treatment with the drug had to be stopped Some patients have nausea and some fatigue In 1 case we had to stop use of the drug because of the Herxheimer-like effect How it acts and whether its reaction will be sustained have not been determined

DR H E MICHELSON, Minneapolis My co-workers and I have tried urethane in Kaposi's sarcoma with no effect We did have some effect with nitrogen mustard We also had temporary results with nitrogen mustard in mycosis fungoides

DR STEPHEN ROTHMAN It was interesting to note in this case that, while the premycotic lesions were highly pruritic, the tumors themselves do not itch In my experience this is the rule Pruritus is present as long as there is a defense reaction of the skin against the deposition of foreign cells After the infiltrating tumor has established itself and started unlimited growth, itching subsides

The experience with nitrogen mustards in Billings Hospital has been that about in 50 per cent of the cases of Hodgkin's disease the cutaneous manifestations react favorably The practical significance of this therapy is that it is effective in cases in which the beneficial effect of roentgen rays has been exhausted However, the final outcome has not been changed so far



DR EDWARD A OLIVER With reference to Dr Cornbleet's patient, I have watched the man for the last seven years He has been a constant attendant in our clinic at Northwestern University, and we have always presented the case as

Kaposi's Sarcoma Presented by DR JAMES H MITCHELL, DR RALPH SCULL and (by invitation) DR B YAFFE

Hidrosadenitis Suppurativa, Acne Vulgaris and Acne Conglobata, DR E E SENFAR and staff

Pustular Psoriasis, Healed After Tobacco Juice Soaks Presented by DR STEPHEN ROTHMAN and (by invitation) DR J H MCCREARY

S J, a housewife aged 57, was presented at the Chicago Dermatological Society meeting of Oct 16, 1946 The diagnoses suggested were pustular

Pustular psoriasis treated with tobacco juice soaks *A*, before treatment *B*, after treatment

psoriasis and acrodermatitis continua She had been hospitalized at the Albert Merritt Billings Hospital from June 12 to October 22 for observation and treatment

The patient was discharged from the hospital, unimproved, one week after the presentation, to be followed as an outpatient While at home, on her own initiative, she soaked her hands in hot tobacco juice six to eight times a day The juice was prepared by boiling tobacco in water for two minutes Each soaking lasted five to ten minutes Within one week considerable improvement

one of psoriasis of the plaque type Itching is present, but I have seen Negroes with psoriasis who do have considerable pruritus He gets worse and gets better I examined the slides, and I do not believe that one could make a diagnosis of mycosis fungoides from them

DR ADOLPH ROSTENBERG (by invitation) What percentage of cases of parapsoriasis en plaque become cases of mycosis fungoides?

DR HAMILTON MONTGOMERY, Rochester, Minn In a fairly large series of cases that I studied with Burkhart (ARCH DERMAT & SYPH **46**.673-690, [Nov] 1942), we came to the conclusion that parapsoriasis remains as such and does not eventuate in mycosis fungoides Mycosis fungoides may start out looking like parapsoriasis and remain as such for many years, but when the cases are studied in the early parapsoriatic-like stage histologic changes of mycosis fungoides are already demonstrable, including clumping of cells, pyknosis, karyorrhexis and multiplicity of cell types in the infiltrate Dr Sweitzer and his associates have presented a case of supposed parapsoriasis many times in the course of the last fifteen years Dr Madden obtained numerous specimens of biopsy from the beginning, about fifteen in number Two thirds of these biopsy specimens revealed definite features of mycosis fungoides, and I anticipate that this patient eventually will have all the clinical features of that disorder

DR S W BECKER I distinctly remember the late Professor Bloch saying that Brocq had abandoned the term erythrodermie pityriasique en plaque disseminée He said that he no longer held to the belief that there was a type of parapsoriasis to which he gave this name

DR OTTO H FOERSTER, Milwaukee There now are perhaps about a dozen undisputed cases of parakeratosis variegata on record The disease in several of the original cases, when seen again at a later time by Unna, was found to have undergone a clinical change and was recognized by him as mycosis fungoides

DR THEODORE CORNBLEET The initial lesion that my patient showed was a well developed tumor, which classified his disease as the d'emblee variety Subsequently there was regression to the second, or infiltrative, stage with extensive lesions Thus various stages may be present simultaneously, and their mode of evolvement and progression may follow different patterns A patient at the Cook County Hospital was treated recently with the relatively new nitrogen mustard method In a disease with a course as capricious as mycosis fungoides it is difficult to be sure, but this form of therapy seemed to have hastened this particular patient's death An autopsy was made, and the heart, liver and other viscera were found to have heavy infiltrates with characteristics of granuloma fungoides Some of the newer fission products may improve the prognosis in the lymphoblastomas, though thus far they have not done what could not be achieved with the older radiation modalities

Sarcoidosis. Presented by DR S ROTHMAN and (by invitation) DR E L LADEN

M H, a Negro woman aged 31, is a seamstress whose illness began in 1942 with a nodular lesion on her left upper arm This increased in size, and new lesions appeared on her face, right arm and left leg in the intervening years

In 1943 she suffered from short-lasting attacks of pain in the left ankle and knee This disappeared spontaneously after ten months In November 1946, she noted swelling of the proximal phalanx of the third finger, right hand This has become progressively worse

The patient was seen by the Chest Department of the University of Chicago Clinics in February 1945 Results of tuberculin skin tests with dilutions of

was seen in all the treated lesions, and almost complete cure of the hands and fingers was achieved in four weeks

Dr Edward Laden of our department could not demonstrate any antibiotic effect of the tobacco juice in vitro

Dermatitis Repens, Therapeutic Result Presented by DR F E SENEAR and staff

E L, aged 63, has been a patient on the dermatology service, Illinois Research and Education Hospital, since October 1946, with the diagnosis of dermatitis repens, affecting the first and second toes of the right foot On a previous admission intractable pain associated with a similar eruption on the left foot had necessitated amputation up to the middle of the thigh During the present period of hospitalization the following therapeutic agents were tried without noticeable improvement penicillin parenterally in large doses, sulfonamide drugs, staphylococcic toxoid, wet dressings of silver nitrate potassium permanganate and benzalkonium chloride, tyrothricin dressings, streptomycin ointment and repeated lumbar sympathetic blocks The most recent treatment has included a course of sulfapyridine by mouth and roentgen irradiation (twelve doses of 50 r, given twice weekly, terminating on May 12, 1947) No improvement was noted Immediately after application of compound tincture of benzoin ointment was started (May 28), oozing and crusting disappeared and epithelization began At present there is only a small area of dry healing granulations at the tip of the great toe

Pustular Psoriasis, Treated with Tobacco Juice Soaks Presented by DR STEPHEN ROTHMAN and (by invitation) DR J C MCCREARY

M K, a white housewife aged 53, was admitted to Albert Merritt Billings Hospital May 18, 1947, presenting widespread psoriasis of forty-eight years' duration Approximately fifteen years ago the palm of the right hand became pruritic and then pustular Some of the joints of the hand stiffened Later the tips of the fingers and toes became red, swollen and full of pustules Some nails were shed Repeated cultures failed to grow bacteria There have been remissions with improvement, of several years' duration, but never complete healing The present flare-up began four months prior to admission

In the past, various methods of therapy had been tried, including local applications of tyrothricin, penicillin, nitrofurazone, chloresium, ammoniated mercury, tar, roentgen irradiations, systemic administration of arsenic and vitamin B complex and a fat-free diet

Examination revealed well circumscribed, erythematous, partly crusted and partly hyperkeratotic patches on the scalp, trunk and upper and lower extremities The hands and toes showed subcorneal pustulation and crusting The right hand showed atrophy and contractures Both hands had stiffened interphalangeal joints Some finger nails and toe nails were missing, others were rudimentary

Wassermann and Kahn reactions of the blood were negative The urine was normal Examination of the blood revealed 12,800 leukocytes The differential count was normal Hemoglobin was 12 8 Gm Erythrocyte cells numbered 3,370,000 Blood lipids and cholesterol were normal The results of the sternal bone marrow examination was normal The basal metabolic rate was + 2 per cent A roentgenogram of the hands showed moderate arthritic changes involving the interphalangeal joints The electrocardiogram showed a tendency to left axis deviation

1 1,000, 1 100 and 1 10 and undiluted tuberculin were all negative A roentgenogram of the chest showed moderate enlargement of the hilar lymph glands bilaterally Results of laboratory studies in 1945, including urinalysis, complete blood cell count, serologic reactions, and serum protein, were all essentially normal No skeletal lesions were found in 1945

The patient was seen in the Dermatology Clinic on May 13, 1947 Examination revealed multiple nodules and plaques on the face, extensor aspects of the arms and the left leg These lesions are firm and elastic to touch Many of the face lesions are depigmented The plaquelike lesions show a tendency toward central involution with a spreading border The lesions are dull brown to purplish Enlargement of the proximal phalanx of the third finger of the right hand was noted A roentgenogram of the hand showed widening of the base of this phalanx The medullary spaces are widened with intervening thin trabeculae The cortex is intact.

Treatment with vitamin D_2 (drisdol®), 150,000 units daily, was started on May 13, 1947 On May 16 she noted a flare-up of the cutaneous lesions with subjective throbbing sensations When seen on May 20, the flare-up had partially subsided, but some swelling was still noticeable

A biopsy specimen of a cutaneous lesion showed mild acanthosis of the epidermis The dermis contains a dense infiltrate consisting of lymphocytes, epithelioid cells and a few polymorphonuclear leukocytes In the deeper part of the corium there are well defined nests of infiltrate surrounded by connective tissue Vascular dilatation and some connective tissue degeneration are present

DISCUSSION

DR H E MICHELSON, Minneapolis I think that Negro patients having what is known as sarcoidosis should be observed in a most thorough manner to determine whether this uniform condition as seen in Negroes is the same as sarcoidosis in white persons, which might enable one to find out whether sarcoidosis is or becomes tuberculosis I have tried vitamin D_2 in 5 patients, with the dosage used in lupus vulgaris, and have seen no appreciable results

DR ARTHUR C CURTIS, Ann Arbor, Mich Although sarcoid is a clinical entity, I do not think that it is an etiologic one, unless one wishes to consider that perhaps a chemical compound is its cause This may be illustrated in the work originally done by Florence Sabin, when she began her work on fractionation of the tubercle bacilli She injected each fraction into animals, and sarcoid lesions developed in those receiving the phosphatide Further work has been done by others The late Dr Gardner, of Saranac Lake, insufflated animal lungs with silica dioxide and obtained typical sarcoid lesions Later Dr Allon in Toronto repeated Gardner's work and obtained the same results but noted considerable fat in the sections He then extracted these lungs with a solvent, removed the silica and reinjected the silica-free material into animals and again obtained sarcoid-like lesions This work indicates that silica may be an etiologic factor in sarcoid, silica produces the phosphatide which Sabin showed to be the chemical substance capable of producing sarcoid in animals

Not long ago a young man was seen with a typical sarcoid lesion of the face, proved by biopsy Dr Weller saw a few particles of silica in this lesion The next time I saw the patient I learned that two years previously he had been in an automobile accident and thrown out of his car, abrading his cheek on a gravel road I think that his sarcoid was due to silica ground into his cheek by the accident

Dr Michelson said that he has used vitamin D_2 without success That is not my experience The patients my co-workers and I have selected have had extensive

Biopsy of left knee joint capsule showed no abnormalities Biopsy of the skin showed changes typical of pustular psoriasis

While the patient was in the hospital, fever therapy was employed four times, with typhoid vaccine given intravenously (each reading 102 F) with no effect On June 4 the patient started soaking one finger in hot tobacco juice Within three days the swelling had gone and the finger had so improved that the patient was encouraged to soak the right hand Treatment has been continued in the following manner The tobacco is boiled for two minutes in water The hands are soaked in the heated extract for thirty minutes, four to six times a day The solution should be as warm as the patient can tolerate without burning

DISCUSSION

DR S W BECKER I think that the disease in all these patients is of the acrodermatitis continue type rather than the pustular psoriasis type The woman with the lesion on the arm shows a definite atrophy following healing, which rules out psoriasis The results from the bizarre treatment are certainly remarkable

DR F E SENEAR We have had this subject up here so often that nearly everything is repetitious I would like to agree with Dr Becker that the disease in these cases, at least the cases of extensive disease, is of the acrodermatitis continue type rather than pustular psoriasis I think that anyone would point out these lesions on the forearm as being a point against acrodermatitis continue, but the lesions on the tips of the fingers with the extensive undermining of the periphery are suggestive of the Hallopeau type

DR ROBERT M B MACKENNA, London, England (by invitation) I agree with everything Dr Senear has said Most of my colleagues would regard these as acrodermatitis continue type of lesions and not pustular dermatitis

DR STEPHEN ROTHMAN The patient started this treatment on her own She heard about it from neighbors The tobacco is boiled for two minutes only Our main purpose in showing these patients was to ask the members of this society to send more patients to us for testing the efficacy of this method with fractions of the tobacco juice in order to isolate the active compounds Of course, we shall need a number of patients with pustular psoriasis and with acrodermatitis Hallopeau to carry out this work

Lupus Vulgaris Improved with Vitamin D_2 Presented by DR F E SENEAR and staff

Lupus Miliaris Disseminata Facei, Improvement from Treatment with Vitamin D_2 Presented by DR HAROLD SHELLOW

Fox-Fordyce Disease, Relief with Testosterone Presented by DR F E SENEAR and staff

Congenital Syphilis, Second and Third Generation Presented by DR JAMES H MITCHELL and DR RALPH SCULL

Lipomelanotic Reticulosis (Pautrier-Woringer Disease) Presented by DR STEPHEN ROTMAN and (by invitation) DR M J SCHERBER and DR E L LADEN

R L, aged 63, was admitted to St Joseph Hospital in Chicago on April 30, 1947, with the complaints of swelling, redness and weeping of the skin of the

the pedigree of a family in which some members had psoriasis, others arthritis and one member arthropathic psoriasis The peculiar observations of the biopsy of the joints will be reported by our orthopedic department In 1 case the verrucous lesions developed the second time around healing psoriatic lesions

Eosinophilic Granuloma Presented by DR EDWARD A OLIVER and (by invitation) DR E LORANT

M E C, a white man aged 42, first noticed a few reddish lesions on his face in January 1943 The lesions developed slowly, and the patient was kept under observation in a Naval dispensary A biopsy was performed in September 1943 and another in March 1944 On both occasions the diagnosis on pathologic examination was "chronic inflammation, probably mycosis fungoides"

From October to December 1943, he had eight roentgen irradiations at weekly intervals, of 75 r each After completion of the irradiations the lesions flattened and changed color from cherry red to pinkish brown However, three months after the roentgen therapy was completed the lesions became active again and have shown occasional activity to date

The patient now shows a quarter-sized lesion on the left cheek, another irregularly shaped quarter-sized lesion on the right cheek and a larger lesion in front of the right ear on the temporal region These lesions are nonelevated and reddish brown and are yellowish brown on pressure with a diascope They are not pruritic

The general physical examination and roentgenograms of the chest, feet and hands showed no evidence of pathologic changes

The urine was normal Examination of the blood showed a hemoglobin content of 87 to 90 per cent, a color index of 0 9, an erythrocyte count of 4,500,000 to 4,600,000 and a leukocyte count of 6,000 to 9,600, with a differential count of 48 to 56 per cent neutrophils, 38 to 46 per cent lymphocytes and 6 per cent eosinophils The sedimentation rate was 2 to 4 mm per hour The total protein was 6 9 mg per hundred cubic centimeters of blood, with an albumin-globulin ratio of 1 7 to 1

In a recent biopsy histologic observations were as follows The epidermis was uniform and apparently not increased in thickness There was slight hyperkeratosis The basal cells were well preserved, with a small amount of pigment present

In the corium completely separated from the epidermis there were large and small clusters of cells as well as cellular infiltrations composed of numerous lymphocytes, an occasional eosinophil, a few plasma cells and a few neutrophils were seen also The blood vessels and lymphatics were slightly dilated and presented occasional perivascular infiltrate There was slight edema throughout the corium The sebaceous and sweat glands were not especially involved

Histologic examination showed the epidermis to be normal In the middle portion of the corium, separated from the epidermis by a narrow band of normal connective tissue, lay a wide horizontal band of cellular infiltrate This cellular mass was densely packed, it was sharply circumscribed, and it included within its borders hairs and sebaceous glands There were many eosinophilic polymorphonuclear and mononuclear cells and many lymphocytes and histiocytes and fewer plasma cells

DISCUSSION

DR H M BULEY, Champaign, Ill During the past eighteen months my co-workers and I have had the opportunity to see several cases of eosinophilic granuloma of the skin representing various types of eruptions As has been stated in previous discussions, it is extremely difficult to find the common denominator for the various pictures presented in these cases I feel, therefore, that it is some-

what premature to suggest common causative factors, at least not until a larger number of case studies have been accumulated The case presented today is comparable to the case described by Pasini in 1940, and also with the case I presented here in November 1945 In these 3 patients the eruption started with macular erythema on the face, which within several months changed to a more or less extensive papular or nodular form Once the lesions reached their maximum size, however, they maintained their clinical appearance It is further remarkable that the disease did not interfere with the patients' general health No pathologic changes were found in either the lungs or the bones Although there was a slight increase in the eosinophil count of the blood the disease was essentially confined to the skin In all 3 cases the lesions were indolent, causing no discomfort to the patient In the patient presented today, relative lymphocytosis (30 to 40 per cent) was found, which, as far as I can recall, had not been noted in the other cases

DR CARL W LAYMON, Minneapolis There have been less than a dozen cases of eosinophilic granuloma of the skin in the literature, and the association of eosinophilic granuloma of the skin and bone is extremely rare The clinical picture of eosinophilic granuloma of the skin is subject to wide variations The lesions may be papules, nodules or plaques which are smooth or verrucous and usually red, purple or brown In the case recently reported by Dr Lewis and Dr Cormia there seemed to be an association between the eosinophilic granuloma and a fungous infection of the feet These observers suggestd that possibly eosinophilic grauloma of the skin might be linked to allergy of infection

DR EDWARD A OLIVER In this case the disease was difficult to diagnose clinically The patient stated that he had been treated in the Navy for mycosis fungoides He had received eight roentgen treatments I knew that it was not mycosis fungoides, and my first impression was that it was sarcoid Dr Caro then examined the sections for me, and his diagnosis was eosinophilic granuloma Dr Buley recently published an excellent article on eosinophilic granuloma in the December 1946 issue of the *Journal of Investigative Dermatology* This disease is most difficult to diagnose clinically because it occurs in so many different forms Only by a careful study of microscopic sections can one be sure of the diagnosis

Urticaria Pigmentosa of Recent Origin in an Adult, with No Mast Cells in the Section Presented by DR S J ZAKON and (by invitation) DR A L GOLDBERG

A Case of Urticaria Pigmentosa in a Child, with Mast Cells in the Corium. Presented by DR E A OLIVER and (by invitation) DR H F GARRARD

Preauricular Sinus Congenita (Bilateral) Presented by DR CLEVELAND J WHITE

Hyperplasia of the Gums Due to the Use of Dilantin® Sodium (Diphenylhydantoin Sodium) Presented by DR E M SMITH JR

DISCUSSION

DR ADOLPH ROSTENBERG JR (by invitation) Dilantin® is chemically closely related to the German drug nirvanol (phenylethylhydantoin) Van Wyk and Hoffmann (Periarteritis Nodosa, *Arch Int Med* **81** 605, 1948) pointed out the paucity of reactions seen with dilantin® and the large number seen with nirvanol, which is interesting considering the extremely close chemical relationship

entire body of one year's duration This ailment started with a pruritic dermatitis on the ankles and elbows, which the patient attributed to contact with brick and lime dust In a few months it had spread to involve the entire body He was treated with local applications and injections with only temporary relief During the first six months of the illness the patient lost 26 pounds (12 Kg) in weight

In March 1947, the patient suffered an acute abdominal episode, which was interpreted as thrombophlebitis of the mesenteric veins, followed by generalized peritonitis

On admission to the hospital in April, there was diffuse erythema, swelling and oozing of most of the body The face and large flexures displayed lichenification Pruritus was intense There was generalized lymphadenopathy with single, hard, enlarged lymph nodes The tongue was beefy red and infiltrated, grayish plaques were present between the soft and hard palate The patient was afebrile

The acute manifestations of the dermatitis were checked by local applications When the patient was seen by the consulting dermatologist at this time the impression was erythroderma due to some lymphoblastomas

Laboratory examinations revealed negative serologic reactions, normal urine, erythrocytes 4,000,000, hemoglobin 10 5 Gm and leukocytes 21,000, with 69 per cent polymorphonuclear cells, 13 per cent lymphocytes, 9 per cent eosinophils, 2 per cent monocytes, 1 per cent basophils and 6 per cent stab cells Plasma proteins were 6 5 Gm per hundred cubic centimeters, albumin 2 8 Gm and globulin 3 7 Gm per hundred cubic centimeters with a ratio of 1 1 3 Sternal puncture showed hyperplasia of neutrophil precursors and a decrease in percentage of erythroblasts The left shift of neutrophil precursors was not pronounced enough to permit a diagnosis of myelogenous leukemia It was thought to be a leukemoid reaction Biopsy of the skin and lymph node was performed The microscopic skin sections showed chronic inflammation with a great number of melanophores and large pale cells with vesicular nuclei In the lymph node specimen the cortex is infiltrated by large pale cells, eosinophils, numerous pigmented cells and some polymorphonuclear and plasma cells

During his hospital stay the patient had two attacks of septic thrombophlebitis with positive blood cultures of hemolytic Staphylococcus albus, each time recovering after penicillin and dicumarol® therapy

The pruritus was greatly relieved by roentgen irradiations Several blood transfusions were given

During the observation period there has been a conspicuous darkening of the skin leading to the now prevailing color shade The leukocyte count has varied between 10,000 and 25,000 The relative lymphocytopenia has become progressively worse, down to 6 per cent lymphocytes with 88 per cent polymorphonuclear cells and a leukocyte count of 17,200

DISCUSSION

DR HAMILTON MONTGOMERY, Rochester, Minn I wonder whether a new name is needed or whether this should be called a new disease One sees deposition of melanin pigment in the lymph nodes in a great many inflammatory conditions, in association with lymphoblastomas, in psoriasis and also in conditions in which there is excess pigment in the skin In the case presented today the second biopsy simply revealed a nonspecific dermatitis, in other words, this man had an exfoliative dermatitis or generalized erythroderma without evidence of lymphoblastoma There is increased pigment in both the skin and the lymph nodes

DR ADOLPH ROSTENBERG JR (by invitation) As I understand this term, it does not really designate a cutaneous diagnosis It is purely a pathologic term

DR W R HUBLER I do not believe that she has pemphigus There are numerous, annular, bullous lesions on the face and shoulders The symmetric distribution of the eruption and the localization on the neck, axillas, elbows, knees and shoulders, as well as the grouping of the lesions, all point to a herpetiform type of eruption The patient is Rh negative, the husband Rh positive, and she is beginning to have anti-Rh antibodies About six months ago she was hospitalized by a gynecologist for what was apparently an early spontaneous abortion This would account for the early rise in anti-Rh titer I do not know what the Rh titer has to do with herpes gestationis, but I feel that some factor might be implicated since it usually clears with termination of pregnancy Therapeutic abortion should be performed in this case, because in a number of cases in which the patients were allowed to go to term, the percentage of monstrosities among living children was much higher than normal and stillbirths were common (Mueller, C *Am J Obst & Gynec* **48** 170-180 [Aug] 1944) Also, in some cases the herpetiform eruption persists after the completion of pregnancy when the patient is allowed to go to full term

NOTE—The follow-up examination of August 1947 showed that the eruption had subsided strikingly after a therapeutic abortion However, punctate, small vesicles persist in the groin and axillas, on the chin and in other scattered areas These are subsiding with inorganic arsenical therapy Hyperpigmentation has developed further showing the relationship to dermatitis herpetiformis The anti-Rh titer, three months after the therapeutic abortion, is only 1 1

Extensive Circumscribed Myxedema Presented by DR M J GIBANS, Akron, Ohio

H O , aged 56, was subjected to a subtotal thyroidectomy in February 1945 because of a toxic goiter Preoperatively the basal metabolic rate varied from + 72 to + 79 per cent, and the blood pressure was 154 systolic and 84 diastolic Postoperative examinations showed metabolic rates of + 27 and + 40 per cent, and finally — 15 per cent, and the blood pressure was 130 systolic and 70 diastolic His weight, which had been 130 pounds (59 Kg) before operation, increased to 179 pounds (81 Kg) thereafter About four months after operation, the patient noticed a little discoloration and redness about the ankles This progressed slowly until some months later, after he had returned to work, when it extended rapidly This has never caused him any discomfort

He now has nonpitting, tawny, elevated, nodular plaques, with moderately enlarged follicular openings, on the anterior aspects of both legs These plaques are much more extensive on the right leg, involving almost the entire lower half and extending over the medial surface and posteriorly, where there is one unusually large and firm mass, about 2 inches (5 cm) in diameter

The microscopic description by Dr Lloyd Catron was as follows There are slightly increased deposits of melanin in the epidermis, with edema of the corium The hair follicles are dilated and plugged with keratohyaline material The small blood vessels are thick walled There is a patchy infiltrate, composed chiefly of lymphocytes, around accessory skin structures The histologic appearances are compatible with circumscribed myxedema The patient has recently been given thyroid extract, 2 grains (130 mg) daily

Bullous Eruption (Pemphigus) Presented by DR E GILLESPIE, Canton, Ohio

Dermatitis Herpetiformis (?) in a Seven Year Old Girl Presented by DR H A HAYNES JR

Hurwitt (*J Invest Dermat* **5** 197 [Aug] 1942) reviewed all the lymph nodes taken out at the Mount Sinai Hospital, New York There is a reticulum and histiocytic cell replacement of the lymphocyte in the lymph node It is purely a benign process and is not related to lymphoblastoma Hurwitt also criticized the term Pautrier-Woringer disease and used the name dermatopathic lymphadenitis About a year later there was an article by Larkin and his co-workers (*J Pediat* **24** 442 [April] 1944) on this same syndrome, with reference particularly to infantile eczema He pointed out that involvement of the lymph nodes is not uncommon in infantile eczema and that these nodes can have a resemblance to those seen in Hodgkin's disease He warned against confusion with manifestations in Hodgkin's disease because this condition is benign

DR S W BECKER I have been of the opinion that this reaction was of a nonspecific variety Someone, some months ago, said that the pathologist at Cook County Hospital considered it a definite entity

DR S M BLUEFARB The original article on lipomelanotic reticulosis was written by Pautrier and Woringer in 1932 (*Bull Soc franç dermat et syph* **39** 947, 1932) They described 6 cases in which the three cardinal signs were exfoliative dermatitis, superficial generalized lymphadenopthy and pigmentation of the skin At that time no specific causative factor was mentioned In a second communication in 1940 Pautrier and Woringer described a case of generalized erythroderma in which typical lesions of mycosis fungoides developed and in which the original lymph node biopsy showed the appearance of lipomelanot c reticulosis and a subsequent one a reticulum cell proliferation found in mycosis fungoides They suggested that there might be a causal relationship between the two conditions At the February 1945 meeting Dr Oliver (ARCH DERMAT & SYPH **54** 621 [Nov] 1946) showed a case of generalized erythroderma with lipomelanotic reticulosis Several months later the patient died of mycosis fungoides

There appear to be several schools of thought regarding the outcome of this disease Dr Rostenberg just mentioned the benignity of this disease I believe that Robb-Smith of England also favors the concept of a benign condition as the patients in the 3 fatal cases in his series appeared to die from intercurrent disease rather than from the skin condition (*Brit J Dermat* **56** 107 [May-June] 1944) However, I do not believe that the disease in all these cases can be considered benign and that one should give a guarded prognosis because in a certain percentage of these cases one of the lymphoblastomas will develop

DR STEPHEN ROTHMAN I share the skeptic attitude of Dr Montgomery concerning the assumption that this is a separate entity On the other hand, the microscopic picture of the lymph nodes is not one of banal chronic inflammation, because the infiltration is invasive, neither does the picture correspond with that of any of the known lymphoblastomas When first seen, this patient had erythroderma with lichenification

Mycosis Fungoides Treated with Sodium Paraaminobenzoic Acid Presented by DR JAMES H MITCHELL

Mrs L McC, aged 52, was presented at the meeting of May 21 At the suggestion of Dr Arthur Curtis, treatment with sodium paraaminobenzoic acid was begun March 29, 1947 Tablets of 2 Gm were taken every three hours during the waking hours The clinical improvement was at first spectacular, but there has been little change in her condition in the past month

Circumscribed Scleroderma Presented by DR F M MCDONALD, Akron, Ahio

Lichen Striatus Involving the Leg of a Four Year Old Girl Presented by DR F M MCDONALD, Akron, Ohio

Porokeratosis of Mibelli Presented by DR C L BASKIN, Akron, Ohio

T N, a 70 year old man, a native of Italy, came to the United States forty-five years ago His inability to understand the English language prevents a complete history in this case His general health has always been good, he has never lost time from work

The present eruption began when he was a small child, gradually spreading from a spot on the left calf to include the entire leg and a large area of the sole The lesions show the characteristic threadlike border and polycyclic configuration There has been a slow steady advance of the margins during these many years All laboratory examinations showed normal values

DISCUSSION

DR G W BINKLEY This is a giant form of porokeratosis of Mibelli In addition to the appearance of the lesion, the long duration and the patient's Italian nationality are points in favor of a diagnosis of porokeratosis of Mibelli There is a sharp border between the normal skin and the involved skin

DR. W R HUBLER I believe that vitamin A has been used in the treatment of porokeratosis of Mibelli with some success At the last meeting of the American Academy of Dermatology a patient with this disease was presented, and several dermatologists stated that they had noted improvement following administration of large doses of vitamin A

A Case for Diagnosis (Tuberculosis Cutis?) Presented by DR G H CURTIS and DR E W NETHERTON

Steatocystoma Multiplex (Pringle) Presented by DR H N COLE and DR J R DRIVER

Epidermolysis Bullosa Presented by DR JOHN BONNER for DR C F MCKHANN (by invitation)

DISCUSSION

DR JAMES H MITCHELL The patient was shown last month, and I asked her to come here especially for examination by Dr MacKenna I might say that since she was last presented she has made less progress than she made previously Dr Ormsby pointed out that many different medicaments could improve mycosis fungoides temporarily, and perhaps this medicament will fit in with what Dr Ormsby has said I have another patient treated by the same method and a third one with leukemia It remains to be seen whether we have anything worth while

NOTE—The patient with lymphatic leukemia died without making a satisfactory trial of the medicament The other 2 patients are still doing well

A Case for Diagnosis (Alopecia Areata? Atrophic Glossitis? Acquired Anhidrosis?) Presented by DR FRANCIS W LYNCH

Miss G L, aged 24, first had a dermatologic condition at the age of 14, when she had a febrile illness, possibly rheumatic fever, followed by a generalized eruption which was first regarded as scarlet fever The eruption recurred three times, accompanied with fever and followed by exfoliation After the last febrile attack the exfoliation continued, accompanied with pyogenic infection especially on the hands, feet and scalp, resulting in loss of the nails and alopecia There was also otitis, conjunctivitis and gingivitis About that time the skin on the chest and abdomen became inflamed and was wiped off easily, leaving a moist red surface which subsequently healed The patient was bedridden seven months She lost 67 pounds (30 Kg) in weight

Subsequently there has been persistent alopecia which is almost total There is photophobia and a severe refractile error There was amenorrhea for one year, but the menses again became normal During hot weather she perspires slightly and becomes weak, and her temperature rises to 103 F or more

The family history is normal except that one sister had eczema in infancy The patient has had occasional urticaria

The scalp is almost bald, with some occipital hair remaining There are a few hairs in the lashes and brows, the body and extremities are without hair The bulbar conjunctivas are slightly red and the palpebral conjunctivas show some pale areas and other inflamed areas (They previously were treated by electrosurgery) The tongue presents superficial atrophy The left buccal mucous membrane shows an irregular area of thickening and possibly scarring All the nails are atrophic and deformed The palms and soles are dry and appear to be scarred The extremities are smooth and hairless, and the skin of the legs is thin There are numerous irregular brown macules on the face and hands

DISCUSSION

DR S W BECKER This is an odd case It started out at the age of 14 when the patient had a severe febrile reaction, during which she lost her hair I suppose it was on a systemic basis Later she had a recurrence of the generalized eruption, which she said looked like scarlet fever It recurred a great many times She had a severe crusting eruption of the scalp She obviously has a certain amount of cutaneous scarring, which I presume resulted from the inflammatory reaction She lost not only her hair but her finger nails as well Her tongue is somewhat atrophic, and I thought that there was a little leukoplakia on the tongue and buccal mucosa The palms and soles were peculiar in that she had fungated keratoses which were a little suggestive of an arsenical keratosis I questioned

Acrodermatitis Chronica Atrophicans Presented by DR A E WALKER and DR W MARMELZAT (service of DR H N COLE and DR J R DRIVER)

Scleredema Adultorum (Buschke) Presented by DR A E WALKER and DR W MARMELZAT (service of DR H N COLE and DR J R DRIVER)

L S, a 51 year old Italian woman, had, approximately twenty months ago, a sudden onset of nonpruritic thickening and tightening of the skin of the neck, which spread to the lateral and anterior portions of the neck, the lateral aspects of the face, back, shoulders, upper arms and upper part of the chest The skin is softer now than it was after onset of the condition The patient has had previous episodes of infection of the upper part of the respiratory tract and influenza but no clearcut episode immediately preceding the onset of her present illness (There is a language barrier and a lucid history is difficult to obtain)

The patient has diabetes mellitus, which is being treated by diet and insulin She also has been treated medically for a hypertrophic arthritis Two years ago she had menorrhagia, the cause of which was never explained

There is painless, nonpruritic thickening of the skin of the back of the neck, extending over the dorsum to the iliac area, laterally around the neck to the anterior aspect, over the shoulders and upper arms to the deltoid area, and over the upper part of the chest and superior portion of both breasts The epidermis is not changed There is no pitting edema There are bilateral xanthelasma lesions

Urinalysis showed sugar (4 plus) and acetone (3 plus) The urea nitrogen was 18 mg per hundred cubic centimeters The fasting blood sugar was 303 mg per hundred cubic centimeters Total proteins were 6 3 Gm per hundred cubic centimeters—albumin 3 8 Gm and globulin 2 5 mg, combining power 52 5 milliequivalents per liter, blood cholesterol 354 mg, serum calcium 9 8 mg and serum phosphorus 4 3 mg per hundred cubic centimeters Results of hemocytologic studies were normal The blood and spinal fluid were normal The basal metabolic rate was +17 per cent Roentgenograms of the chest, sinuses, jaw and skull were normal

Biopsy of the skin revealed the epidermis to be normal The corium was thickened, made up of deeply acidophilic, greatly hypertrophied collagenous fibers The small vessels and capillaries were not remarkable but were surrounded by a moderate infiltration of lymphocytes and occasional polymophonuclear leukocytes No treatment has been given

DISCUSSION

DR H A BRUNSTING What is the duration of the disease?

DR R C LIGHT In the *New England Journal of Medicine* several months ago there was a report of a case of twenty years' duration

DR A E WALKER Another review I saw listed 1 case lasting thirty years and 1 four years The average is eight to eighteen months

Sarcoidosis (Granuloma Annulare [?] of the Elbows and Knees) Presented by DR A E WALKER and DR W MARMELZAT (service of DR H N COLE and DR J R DRIVER)

Sarcoidosis (Keloidal Lesions on the Nape of the Neck) Presented by DR A E WALKER and DR W MARMELZAT (service of DR H N COLE and DR J R DRIVER)

her closely but could get no history of the ingestion of arsenic I simply think that we have to decide whether this entire picture should be included in a single dermatologic entity, which I rather doubt at present

DR HAMILTON MONTGOMERY, Rochester, Minn I thought this was a case of congenital defect She has a flat nose You could not call it a congenital ectodermal defect with the changes in the tongue, but we have seen cases of endodermal and ectodermal changes merging together She did not have changes in the teeth but had changes in the palms that might indicate an ectodermal defect, as would the changes in the neck In addition she has apparently had a dermatitis which does not belong with that picture I would suggest that her family history be investigated

DR FRANCIS W LYNCH, St Paul, Minn I thought of the possibility of an ectodermal defect, but the mucosal changes were too great The family history is normal as far as could be learned on brief questioning

Darier's Disease (Keratosis Follicularis), Improvement Following Vitamin A Therapy Presented by DR S J ZAKON and (by invitation) DR A L GOLDBERG

Oct 23 1947

Congenital Ichthyosiform Erythroderma, Persistent Notochord Presented by DR M H GUSTAFSON, DR E H JONES JR and DR M UTTERBACH (service of DR J E RAUSCHKOLB and DR G A DEOREO)

Nonspecific Dermatitis, Associated with Lymphoblastoma Presented by DR M H GUSTAFSON, DR E H JONES JR and DR M UTTERBACH (service DR ROY W SCOTT)

Lymphangiectasis of Vulva, Secondary to Probable Tuberculous Salpingitis, Pulmonary Tuberculosis, Moderately Advanced Presented by DR M H GUSTAFSON, DR E H JONES JR and DR M UTTERBACH (service of DR J E RAUSCHKOLB and DR G A DEOREO)

A S, a 29 year old woman, was first seen on the dermatologic service in September 1947, complaining of pruritic lesions of the vulva, of four months' duration She said that they had gradually increased in size and that the pruritus had become much more pronounced in the previous three weeks, with some weeping of the lesions She noted that a watery material was obtained from the individual lesions if she pricked them with a needle

Both the labia majora and the labia minora are covered with acuminate, cystic lesions, which are slightly tender and moderately pruritic The lesions are tense and are filled with a thin, colorless fluid Large, nonpigmented, polypoid lesions surround the external anal orifice Numerous healed scars are present on the abdomen and thighs The anal sphincter admits the index finger only, with much pain The rectum, within the reach of the examining finger, exhibits no abnormalities Bronchovesicular breath sounds, with fine, post-tussic rales, are heard at the apex of the right lung

Reactions to a skin test with old tuberculin (1 100,000) were positive Those to the Frei test were negative The Kline and Wassermann reactions of the blood were negative Results of urinalysis and the hemogram were within normal limits The roentgenogram of the chest revealed moderately advanced pulmonary tuberculosis of the upper lobe of the right lung

Histologic examination showed that the papillary projections of the epithelium were elongated and that there were many clusters of lymphocytes and plasma cells scattered throughout the underlying stroma, especially about the capillaries Just beneath the epithelium there were many dilated lymphatic spaces

Folliculitis Decalvans (?) Presented by DR JAMES H MITCHELL and DR ROBERT H HARRIS (by invitation)

Eczema Vaccinatum Presented by DR F E SENEAR and staff

A Case for Diagnosis (Secondary Vaccinia [Autoinoculation]) Presented by DR F E SENEAR and staff

Penicillin was administered, with pronounced diminution of the secondary infection The patient was transferred to Sunny Acres, Cuyahoga County Tuberculosis Hospital, for treatment of her tuberculosis

A Case for Diagnosis (Granuloma Telangiectaticum?) Presented by DR M H GUSTAFSON, DR E H JONES JR and DR UTTERBACH (service of DR H R TRATTNER)

G S, a 50 year old man, was first seen on the urologic service in September 1947, with a complaint of numerous growths on the penis and the scrotum, of two years' duration The lesions started as a papule on the dorsum of the penis and gradually increased in number and size, finally involving the entire penis, the scrotum, the perineum and the perianal area The lesions have been asymptomatic

The patient gave a history of having had gonorrhea in 1929 A urethral stricture developed in 1932 In 1933 the first of a series of urinary fistulas appeared, and since that time numerous fistulas have developed around the base of the penis, the scrotum, the lower part of the abdomen and the perineum

The shaft of the penis, the scrotum, the perineum and the perianal area are covered with a fungating, polypoid mass The surface of the mass presents numerous flesh-colored nodules, pedunculated tumors ranging from a few millimeters to 3 cm in diameter Several fistulous openings may be identified in the crevices between the polyps Urethral strictures are present, preventing the passage of sounds

Results of urinalysis and the hemogram were normal The blood urea nitrogen was within normal limits The Kline and Wassermann reactions of the blood were negative Reactions to the Frei test and to skin tests for chancroid were negative An intravenous pyelogram revealed a normal right kidney and ureter, the left kidney was poorly visualized There was a slight hydroureter in the lower portion of the left ureter Suprapubic cystostomy revealed a normal bladder

Histologic examination showed stratified squamous epithelium, the seat of chronic inflammation, with fibrosis of the corium and areas of acute inflammation with focal ulceration

Treatment has consisted of the administration of penicillin and suprapubic cystostomy in preparation for plastic repair

DISCUSSION OF PRECEDING CASES

DR G A DEORDO I think that both of the preceding cases are manifestations of lymphostasis, associated with lymphatic blockage, in the woman due to tuberculosis and in the man resulting from obliteration of the lymphatics by some chronic inflammatory process associated with his gonorrheal infection Clinically at least, the growths looked like lymphangiomas, a form of elephantiasis Microscopically, the picture in the man looked considerably different There are many dilated capillaries or possibly lymphatics with thicker walls I should offer the diagnosis of elephantiasis or lymphangioma in both cases

DR F M MACDONALD I have never seen elephantiasis due to granuloma inguinale This is not the usual picture, but for the sake of work-up it is a very unusual situation I did not see any reference made to examination for possible Donovan bodies Perhaps that was done and I did not see mention of it on the report

DR J E RAUSCHKOLB The case of A S is a lymphostatic type of disorder, that contention is proved There are elevated little cystic lesions, and the lymphostasis probably arises from a chronic inflammatory pelvic condition, which we assume to be of a tuberculous origin

her closely but could get no history of the ingestion of arsenic I simply think that we have to decide whether this entire picture should be included in a single dermatologic entity, which I rather doubt at present

DR HAMILTON MONTGOMERY, Rochester, Minn I thought this was a case of congenital defect She has a flat nose You could not call it a congenital ectodermal defect with the changes in the tongue, but we have seen cases of endodermal and ectodermal changes merging together She did not have changes in the teeth but had changes in the palms that might indicate an ectodermal defect, as would the changes in the neck In addition she has apparently had a dermatitis which does not belong with that picture I would suggest that her family history be investigated

DR FRANCIS W LYNCH, St Paul, Minn I thought of the possibility of an ectodermal defect, but the mucosal changes were too great The family history is normal as far as could be learned on brief questioning

Chronic Urticaria Due to Intestinal Organisms, "Giardia Lamblia", "Cure" Following Treatment with Quinacrine Hydrochloride Presented by DR JAMES H MITCHELL and (by invitation) DR ROBERT H HARRIS

The case of G S is of a condition I have never seen before, however Clinically, this looks like the male counterpart of an esthiomene, in which there is a urinary passage in the perineal area There are thickening and chronic inflammatory changes in the rectum and exuberant fibrotic growths on the penis and the pubic area The condition has improved tremendously in the last months from simply a little plastic surgery and the use of penicillin to clear up the secondary infection The Frei test, skin tests for chancroid and serologic tests gave negative reactions We found no smear positive for fusiform bacilli of Vincent Unfortunately, the smear for Donovan bodies was not made because the case was not into our service, although we recommended that it be done The disorder has probably resulted from a long-standing gonorrhea in which there was a posterior stricture and a false passage which opened in the perineum, with extravasation of urine into the structures adjacent to it, chronic inflammation of the structures and secondary infection being produced The diagnosis of granuloma telangiectaticum pyogenicum probably was made because there was an infected granuloma, although clinically the tumor is not the pyogenic type

Psoriasis Arthropathica Presented by Dr M H Gustafson, Dr E H Jones Jr and Dr M Utterbach (service of Dr Roy W Scott)

Morphea or Lichen Sclerosus et Atrophicus(?) Presented by Dr M H Gustafson, Dr E H Jones Jr and Dr M Utterbach (service of Dr J E Rauschkolb and Dr G A DeOreo)

Multiple Benign Cystic Epithelioma, Alopecia Areata Presented by Dr M H Gustafson, Dr E H Jones Jr and Dr M Utterbach (service of Dr J E Rauschkolb and Dr G A DeOreo)

H D, a 44 year old woman, has four siblings, her mother and a sister have lesions similar to hers The patient has a daughter, aged 23, who is just beginning to exhibit similar lesions

Acrokeratosis Verruciformis Presented by Dr M H Gustafson, Dr E H Jones Jr and Dr M Utterbach (service of Dr J E Rauschkolb and Dr G A DeOreo)

W H, a 16 year old girl, was first seen in the dermatologic service in June 1947, with lesions on the hands and feet, which have been present since birth They have produced no symptoms and have not changed in size since puberty

The patient's aunt and father have had similar lesions since birth The patient was treated with penicillin therapy for secondary syphilis, ending Sept 19, 1947 She was hospitalized for acute and chronic pelvic inflammatory disease in 1946 She states that her parents are not related by blood

Over the proximal interphalangeal joints and the knuckles of both hands are multiple, firm, keratotic papules, measuring 2 to 8 mm in diameter Over the medial and lateral aspects of both palms and soles and the tendo achillis are multiple, small, discrete, firm papules

The roentgenogram of the chest showed normal conditions The results of urinalysis and the hemogram were normal The Kline and the Wassermann reactions of the blood were 4 plus, with a titer of 1 64

Folliculitis Decalvans (?) Presented by DR JAMES H MITCHELL and DR ROBERT H HARRIS (by invitation)

Folliculitis Decalvans Presented by DR F E SENEAR and staff

A Case for Diagnosis (Leprosy?) Presented by DR F E SENEAR

Linear Lichen Planus Presented by DR JAMES H MITCHELL and DR RALPH SCULL and (by invitation) DR BERNARD YAFFE

Widespread Morphea with Acute Development Presented by DR STEPHEN ROTHMAN and (by invitation) DR LOUIS RUBIN

Two Cases for Diagnosis (Unrelated), (Lichen Sclerosis et Atrophicus?) Presented by DR THEODORE CORNBLEET

Eosinophilic Granuloma Presented by DR EDWARD A OLIVER and (by invitation) DR E LORANT

Pityriasis Rubra Pilaris Presented by DR S ROTHMAN and (by invitation) DR J H MCCREARY

Eczema Vaccinatum Presented by DR F E SENEAR and staff

A Case for Diagnosis (Secondary Vaccinia [Autoinoculation]) Presented by DR F E SENEAR and staff

Histologic examination showed pronounced hyperkeratosis, unusual prominence of the stratum granulosum, acanthosis and superficial chronic perivascular inflammatory infiltration of the corium

Since follow-up antisyphilitic therapy was instituted with bismuth subsalicylate, the patient says that the lesions have regressed for the first time

DISCUSSION

DR M UTTERBACH This patient gave a history of similar lesions in other members of her family, which I think is significant It is difficult to evaluate the lesions themselves We considered diagnosis of acrokeratosis, hydrokeratosis and perhaps linear nevus Biopsy showed definite proliferation of the corium Therefore we thought of the possibility of an acrokeratosis

DR H A HAYNES JR I have never seen a case like this, but the disorder could be verruca plana, inasmuch as it is undergoing involution with therapy

DR H J PARKHURST I thought that clinically on close inspection these do not appear to be ordinary warts They resemble the lesions in a case which I previously saw of epidermodysplasia verruciformis

DR G W BINKLEY It would be interesting to get a progress note on this case

Glossitis Rhomboidea Mediana Presented by Dr BENJAMIN P PERSKY

A Case for Diagnosis (Palmar and Plantar Keratoses [Arsenic?] [Keratoderma Disseminatum Palmaris et Plantaris]? Superficial Epitheliomas, Trunk Ulceration, Left Small Toe and Left Palm [Squamous Cell Epithelioma?]) Presented by DR B LEVINE, DR B PERSKY and DR I L SCHONBERG

A Case for Diagnosis (Ulcer, Penis, Cause Undetermined? Erythroplasia of Queyrat? Intraepidermal Epithelioma?) Presented by DR H H JOHNSON and DR I L SCHONBERG

J T, a Negro aged 32, was circumcised in February 1945, since which time there has been a superficial ulcer on the glans penis He has been hospitalized on numerous occasions since 1945 because of this penile lesion The treatment has included the administration of penicillin and numerous local medications, without any signs of improvement during this two year period

On admission to the service in May 1944 the patient was found to have a positive serologic reaction and was treated with a series of injections in the arm and the hip In 1945 he received 146 injections of penicillin because of the positive

Diffuse Progressive Scleroderma Presented by DR J KAM, DR R C LIGHT and DR A E WALKER (Service of DR H N COLE and DR J R DRIVER)

Perifolliculitis Abscedens et Suffoidiens Capitis (Hoffman) Presented by DR J KAM, DR R C LIGHT and DR A E WALKER (Service of DR H N COLE and DR J R DRIVER)

DISCUSSION

DR R C LIGHT There was pronounced improvement after the patient received two treatments of filtered roentgen rays

DR J R DRIVER I should like to ask whether any of the members have treated a condition of this kind with penicillin by injection and what the result has been

DR G H CURTIS I saw 2 patients in the Army treated with 8,000,000 units of penicillin without any benefit

DR H N COLE There were several of these patients at City Hospital, with chronic conditions They were given penicillin by injection and also treated locally with penicillin and penicillin irrigations, without any effect The disease in this case is relatively recent, which I believe is the explanation for the response

Severe Generalized Excoriations Associated with Jaundice (Possible Xanthomatous Biliary Cirrhosis) Presented by DR J KAM, DR R C LIGHT and DR A F WALKER (Service of DR H N COLE and DR J R DRIVER)

reactions to the serologic test for syphilis Numerous lumbar punctures have shown no abnormalities

His blood pressure is 154 systolic and 110 diastolic Examination of the genitalia reveals a 2 by 3 cm ulcer on the left side of the dorsal surface of the glans penis, extending down to the shaft The ulcer has a red, granulating base, partially covered by a thick, dry crust, and the edges of the ulcer are slightly thickened and rolled The lymph nodes are not remarkable

In June 1946 the reaction to the Kahn test was 4 plus, with 10 Kahn units, and reactions to the complement fixation test were negative, however, on two occasions in November the serologic reactions were negative Several urinalyses have shown a specific gravity from 1 010 to 1 022, and on several occasions there have been white blood cells with clumping Biopsy of the penile lesion showed acute inflammation of the skin, with ulceration and atypical hyperplasia of the epithelium An electrocardiogram showed an essentially normal record, with slight elevation of the S-T segment

A Frei test gave negative reactions, and no definite inclusion bodies were seen on the slide of the biopsy specimen The patient has concluded a course of streptomycin, consisting of 4 Gm a day for six days The only other medication has been warm saline compresses to the penile lesion On this therapy there has been definite healing at the periphery of the ulcer and the ulcer is now approximately 1 cm smaller in diameter

The following is the report of the microscopic examination "Examination revealed that the epithelium was ulcerated The ulcer was densely infiltrated with many lymphocytes and plasma cells Over the ulcer there were necrotic debris and many polymorphonuclear leukocytes There were islands of epithelial cells in which the nuclei were large and vesicular, and there were a few large, irregular, oval bodies, resembling somewhat a molluscum body Some of the epithelial cells showed metallic diversion The diagnosis was acute inflammation of the skin, with ulceration and atypical hyperplasia of the epithelium"

DISCUSSION

DR G A DEOREO I think that this man has granuloma inguinale The rapid improvement on treatment with a relatively short course of streptomycin also points toward this diagnosis It is true that there are certain findings in the biopsy which suggest pseudoepitheliomatous hyperplasia, but these changes are frequently seen in granuloma inguinale

DR J E RAUSCHKOLB The chronicity of the lesion, the lack of pain and the resistance of the disorder to ordinary antisyphilitic drugs point, as Dr DeOreo says, to pseudoepitheliomatous hyperplasia, but the condition is not neoplastic in character, and it cannot be anything else but granuloma inguinale One ought to be able to find Donovan bodies, however

DR H N COLE This is a very interesting case One hesitates to make two diagnoses if one will suffice I have seen sections from a large number of cases of granuloma inguinale, and I have seen several examples of pseudoepitheliomatous hyperplasia, but I have never observed anything like the condition this man presents, as seen in the section I do not see how one can avoid calling this disorder intraepithelial carcinoma as well as granuloma inguinale Of course, in Negroes one does not very often see epitheliomatous changes on the skin, but this section shows such a remarkable picture that I do not see how we can refuse to make that diagnosis It would be interesting to have another report on this patient later

1 Boeck's Sarcoid 2 Early Latent Syphilis, Partially Treated Presented by DR J KAM, DR R C LIGHT and DR A E WALKER (Service of DR H N COLE and DR J R DRIVER)

A Case for Diagnosis (Dermatitis Repens?) Presented by DR H H JOHNSON and DR A M TANNO (by invitation)

Alopecia Liminaris Frontalis (Sabouraud) Presented by DR J KAM, DR R C LIGHT and DR A E WALKER (Service of DR H N COLE and DR J R DRIVER)

F W, a Negro woman aged 28, first noticed mild acne of the face and the gradual onset of alopecia of the frontal region of the head in October 1945 Within several months this reached its peak and has persisted to the present There is no history indicative of an endocrine disturbance She has used petrolatum on her hair for many years There is no family history of similar disease

Results of a general physical examination were normal, and she appears in good condition In the frontal portion of the scalp there is a symmetric, well defined band which is almost completely devoid of hair This extends from ear to ear and 3 to 5 cm back of the hair line There is conspicuous plugging of the follicles throughout, and the skin is slightly depressed, suggesting atrophy No erythema is seen There is mild papular acne of the face

Observations in hemograms and urinalyses were normal The result of the serologic test for syphilis was negative The basal metabolic rate was +16 per cent

On histologic examination, the epithelium showed no significant change There was a scattered infiltrate of lymphocytes, histiocytes and pigmented mononuclear cells in the upper part of the corium and to a lesser extent in a few deeper areas around the hair follicles Keratotic plugs often blocked the mouth of the follicles, which frequently contained no hair A trial course of 100,000 units of vitamin A daily for two months had no objective effect

DISCUSSION

DR H G MISKJIAN I have been interested in this subject for some years, after I read a long description of the syndrome given in the *Annales de dermatologie et de syphiligraphie* in 1931 by Sabouraud, in which he said that he had seen 12 cases of this disease in thirty years In the last ten or more years my co-workers and I have, here at the Lakeside Clinic, seen at least 10 or 12 cases, which were all in Negro women, and as far as I remember, all of them were in adults Sabouraud saw his cases in girls of acne age, about 15 to 18, and he mentioned a woman about 50 years old who had it, I have brought the book in which the picture of that woman appears This shows that there are differences between what Sabouraud reported and what we have seen here One of the differences is that in the syndrome we have seen the disease seems to be much more frequent than Sabouraud reported The second point of difference is that our cases are in adults and Sabouraud's were almost entirely in adolescents A third difference is in frequency, we have seen them much more frequently at our clinic The description seems to correspond closely with that of Sabouraud A patch of alopecia would develop on each preauricular temporal region, which would secondarily spread onto the forehead, toward the midline, with a band of alopecia about 1 inch (2 5 cm) or a little less Right on the fringe of the forehead and the band of alopecia there is usually a thin line of hair The patient presented today had that also The alopecia is supposed to be permanent, once it has been estab-

Keratosis Follicularis (Darier's Disease) Improvement After Therapy with Vitamin A Presented by DR E L GLICKSBERG

A Case for Diagnosis (Erythema Elevatum Diutinum? Eosinophilic Granuloma?) Presented by DR I L SCHONBERG

S F, a white man aged 62, first noted swellings on the head and the left arm in 1926 At that time he was treated with various methods, including roentgen irradiation and use of solid carbon dioxide After the application of the solid carbon dioxide an ulcerated area, which required many months to heal, developed on the scalp Since that time the patient has acquired new tumors on the left part of the chest and on the nose These have grown slowly and have darkened About three months ago several nodules were removed surgically from the left breast and the left arm The lesions have been asymptomatic

General physical examination showed essentially normal conditions On the front and the left side of the nose there are two nodules, one the size of a bean and the other the size of an almond The tumors are sharply demarcated, reddish brown and firm to palpation On the left arm there are two dollar-sized areas of atrophy, at the border of which there are pea-sized to bean-sized violaceous nodules There is an atrophic, circular scar, 6 cm in diameter, on the scalp

Treatment has consisted of irradiation with filtered roentgen rays, without results

The results of urinalysis were normal, as was the examination of the stools The hemogram revealed 5,200,000 red blood cells, 10,000 white cells, and 13 Gm of hemoglobin, with a differential count of 62 per cent polymorphonuclear cells, 38 per cent lymphocytes and no eosinophils Testing for allergic reactions gave negative results

A biopsy specimen taken from the wall of the chest showed in the dermis and underlying subcutaneous tissue a circumscribed nodule, measuring about 1 cm in long diameter The central portion of the nodule was composed of dense bundles of collagenous fibers, which were diffusely infiltrated by wandering cells Toward the periphery of the nodule the blood vessels were prominent and considerably increased in number and showed pronounced perivascular infiltration by wandering cells, among which eosinophils predominated The most characteristic changes appeared to be at the base of the lesion in the subcutaneous fat, with vessels thickened there, the media showed slight infiltration by eosinophils, and the regional stroma showed intense infiltration by wandering cells, among which eosinophils predominated

At one edge of the nodule in the dermis there were large bundles of smooth muscle, apparently hypertrophied smooth muscle of a tortuous artery The epidermis was thinner than average, and interpapillary projections were obliterated There was a moderate amount of brown granular pigment in the basal epithelial cells

A second biopsy specimen, taken from the arm, showed a similar picture, but with less advanced sclerosis of the central portion of the nodule than was seen in the material from the wall of the chest At the base of the lesion there was a thick-walled blood vessel In the lesion itself there are numerous blood vessels showing intense cellular infiltration of the vascular wall and perivascular tissue, in which eosinophils predominate

Section stained by the azocarmine method showed an increase in blue-stained fibrous tissue, especially in the lesion from the chest wall, and abundant red-stained smooth muscle bundles in the area, suggesting tortuous or aneurysmal blood vessels in the dermis

lished, and one is supposed to see in the bald area small cicatricial lesions, which I was not able to see in this case I think it would be a very worth while contribution to bring together all of these cases to study them and point out that this syndrome is perhaps more frequent in the Negroes than in white person Nothing is known about it, because Sabouraud seemed to think that the syndrome must be placed between what he calls staretoid baldness, in other words alopecia, and an acneform process, because in the early stages he was able to see acne lesions in areas which later became bald There is a good description of this syndrome in Dr Sutton's book, "Diseases of the Skin," which is accurate

DR J A GAMMEL A few months ago I had a Negro woman patient with what I called alopecia areata, limited to the same areas, which cleared up very well in three months

DR H G MISKJIAN When this patient first came to us we considered the diagnosis of alopecia areata, because the case was not so very characteristic, and we ruled it out at that time At the present time the appearance is not that of alopecia areata There are thin areas that one would ordinarily not see in alopecia areata

DR J A GAMMEL I do not want to make a diagnosis in this case, but merely comment that I saw one with the disease limited to these areas There was complete baldness for two weeks, and in three months the whole process was over

DR H H JOHNSON There is one thing that Negro women do that is peculiar to their race, and that is using various methods of attempting to straighten hair I believe that that should be investigated thoroughly to find out what methods they use to accomplish it

Herpes Gestationis Presented by DR W R HUBLER, Youngstown, Ohio

DISCUSSION

DR J E RAUSCHKOLB This patient has neither oral nor ocular lesions She is two or three months pregnant In spite of this eruption having followed the beginning of pregnancy, I believe that the case is one of pemphigus vegetans because of the extreme prostration and toxicity and the grouping of the bullae on the neck band and axillary and genital areas, which are beginning to pile up and vegetate

DR C G LA ROCCO I agree with Dr Rauschkolb

DR J R DRIVER I agree with the diagnosis as presented There was no Nickolsky sign The woman is pregnant and has had this eruption since her pregnancy started A therapeutic abortion is indicated

DISCUSSION

DR G H CURTIS Clinically, the disease looked like sarcoidosis

DR B LEVINE I saw this man some years ago, and I thought at that time that he had sarcoidosis Many other dermatologists have seen him since

DR G A DEORIO In the 2 cases of erythema elevatum diutinum that I have seen, the edges of the lesions were more perpendicular than they are in this case and the surface formed a plateau The color was not quite as intense as in this case, and the microscopic picture was considerably different from the one we see in this case I should like to suggest the possibility of Kaposi's hemorrhagic disease

DR B PERSKY I should not quite agree with the diagnosis of eosinophilic granuloma here because of the absence of large cells either in the skin or in the bone There were quite a few eosinophils, but I do not think they would add up to the number seen in eosinophilic granuloma I have had occasion to deal with a case of erythema elevatum diutinum, with the characteristic features This case showed ring-shaped lesions around the digits and around the joints, quite blue but not as deeply blue as the lesions in the present case The lesions here somewhat resembled granuloma in that they had a smooth surface and an annular configuration They did not show the picture of granuloma annulare histologically There is one other possibility which I should like to suggest I am not at all sure how accurate the history is I should like to suggest the possibility of periarteritis nodosa There were some vascular changes I think that more biopsies might reveal those features, and possibly further observation and a fuller history as to whether there were remissions or relapses might help

DR I L SCHONBERG When I saw this patient for the first time I was very confused, as you might expect, and on going over his history there were several things that I thought of I was hoping that when I made the biopsy the diagnosis would be sarcoid, but unfortunately it could not be made on the section However, there was a new lesion at the base of the left breast, and we also decided to take a border specimen from the lesion of the left arm On pathologic examination, the condition was reported as periarteritis nodosa I do not feel that the disorder falls in that class, at least clinically On reading the literature, I became more and more confused as to whether or not it fitted in with that diagnosis In the February 1947 issue of ARCHIVES, pages 155 to 201, there are three or four articles on erythema elevatum diutinum and eosinophilic granuloma The examination of the section did not reveal a picture fitting into the type of erythema elevatum diutinum as described by the first author, but observations did fit in with the picture described by Weidman He stated that erythema elevatum diutinum presents a polyarteritis with a cellular infiltrate He quoted an Italian dermatologist, who described a case almost identical with the one I have shown He described lesions on the extensor surface of the hands, the ears, the face and the buttocks According to some of the descriptions, many of these cases began in early life However, there was a group of cases in persons usually over 40 years of age, who presented similar lesions Two types were described the "Hutchinson type," or soft type, with soft plaques, and the "Bury type," with hard nodules which undergo a purplish discoloration There is also a third type, which resolves by itself It is rather difficult to classify this case, but I do feel that there are some indications that it fits into one group or the other

DR S J ZAKON I wonder whether dilantin® is responsible for the hyperplasia or the poor oral hygiene of epileptic persons I had 1 case of this type which I referred to the dentist for oral prophylaxis, and the hypertrophy subsided in spite of the patient's taking dilantin®

DR STEPHAN ROTHMAN I saw a severe generalized hemorrhagic toxic eruption following the use of dilantin,® but the patient did not display hypertrophy of the gums

DR E M SMITH JR This patient was examined by several dentists, who readily agreed that the hypertrophy was a typical result of the long-continued use of dilantin® sodium and that such cases were moderately common in their experience

Dermatomyositis with Slightly Lichenified Lesions on Exposed Surfaces Presented by DR F E SENEAR and STAFF

Lymphocytoma Presented by DR O H FOERSTER, DR H R FOERSTER and (by invitation) DR D M RUCH

D E, a white woman aged 38, had a "pimple" on the right lateral aspect of the forehead in 1938 which she picked and scratched This became hard and raised and remained pea sized until 1945 Since then it has grown gradually, until it is now about four times its original size In 1942 a similar lesion appeared suddenly on the right side of the forehead above the original lesion, and in April 1946 a third similar lesion appeared lateral to the first one Neither of the latter two lesions have changed in size or appearance

On the right lateral aspect of the forehead, 2 cm above the lateral supraorbital margin, is a smooth, firm, cutaneous nodule, elevated about 4 mm Two similar round 5 mm lesions are also present, one 2 cm lateral to the former lesion and the other 0 5 cm above it

Histologic examination showed acanthosis to be present in some areas of the epidermis, and there was condensation in the collagen of the subpapillary layer Areas of lymphocytic infiltrates together with a few plasma cells were present about the glandular structures and in circumscribed areas deep in the corium

A blood cell count (March 18, 1947) showed hemoglobin 90 per cent, leukocytes 7,870, erythrocytes 4,590,000 and color index 1 00 The differential count showed 65 per cent neutrophils (2 per cent nonsegmented and 63 per cent segmented), 2 per cent eosinophils, no basophils, 30 per cent lymphocytes (large 1 per cent, small 29 per cent) and 3 per cent monocytes The blood smear was normal

DISCUSSION

DR M R CARO This patient presents a condition which is difficult to diagnose clinically 'The most obvious diagnosis clinically would be sarcoid, but on histologic examination these small accumulations of lymphocytic cells without any inflammatory reaction are diagnostic for lymphocytoma In the cases reported in the literature there are no observations in the blood stream to make this condition of more serious prognosis I recall a patient presented about ten years ago before this society with a lesion under the eye identical with that in the present case The lesion disappeared after three or four fractional doses of roentgen rays without any recurrence

DR ADOLPH ROSTENBERG JR (by invitation) In the eleventh supplement to 1943 Acta dermato-venereologica there is an article on lymphadenosis benigna cutis There is a fine English summary In lymphadenoma there are two varieties,

in one there are isolated lesions such as this patient apparently has In the other variety there are multiple lesions, but in both the prognosis is about the same There is rarely systemic involvement An isolated cyst as this can arise at any age, whereas the generalized disseminated form is more often in elderly persons The author expressed the belief that a variety of stimuli are etiologic

DR HARRY FOERSTER, Milwaukee We presented this patient chiefly because of the frequency with which lesions of this type are misdiagnosed when they are not subjected to histologic study When first seen by us, the nodules appeared nevoid The history of progressive growth with appearance of new lesions in recent years, one as recently as nine months ago, suggested the possibility of endothelioma Sarcoid and sarcoma were also considered

Dr Caro made the diagnosis of lymphocytoma and also prepared the sections that were shown here today This patient received roentgen treatment about six weeks ago, and the lesions have been reduced about one third in size The pigmentation noted was caused or intensified by the roentgen therapy At the time this patient was being studied, we saw a woman with a similar lesion, and in the same site, which was shown to be an endothelioma on histologic examination

Albright's Syndrome (Fibrous Dysplasia of Bone, Precocious Puberty and Café au Lait Spots) Presented by DR F E SENEAR and STAFF

Francis W Lynch, M D, *President*

Leonard F Weber, M D, *Secretary*

April 16, 1947

A Case for Diagnosis (Streptococcic Eruption on the Face? Seborrheic Dermatitis?) Presented by DR JAMES HERBERT MITCHELL and (by invitation) DR ROBERT M GOODWIN

Pulsating Hemangiomas, Hepatic Cirrhosis Presented by DR T CORNBLEET and (by invitation) DR H SCHORR and DR J GRAFFIN

C D, a white woman aged 52, entered a medical ward at the Cook County Hospital on March 10, 1947 At this time she was given the diagnosis of cirrhosis of the liver with jaundice and ascites She was unable to give a history concerning the dermatitis of her forearms or the telangectatic lesions of her hands and face

Examination reveals a pulsating split-pea-sized lesion in the center of telangectasia on the right cheek The dorsum of the left hand has four smaller pulsating hemangiomas with a keratotic surface Both forearms and lower legs have a fairly well defined dermatitis The abdomen and chest show prominence of the superficial veins, and there are numerous telangiectases There is moderate ascites and icterus of the scleras Her temperature, while in the hospital, has steadily dropped from 102 to 99 F

The Kahn reaction of the blood was negative Repeated urinalyses revealed only a pronounced urobilinogen content The examination of the blood showed hemoglobin 58 per cent, erythrocytes 3,100,000 and leukocytes 8,100 The icterus index was 25 and 14 units The total protein was 6 1 Gm per hundred cubic centimeters, albumin 16 and globulin 4 5

The result of the cephalin flocculation test was 4 plus The nonprotein nitrogen was 31 mg per hundred cubic centimeters

MANHATTAN DERMATOLOGIC SOCIETY

Wilbert Sachs, M D, *Secretary*

March 11, 1947

Erythroplasia of Queyrat Cured. Presented by DR E W ABRAMOWITZ

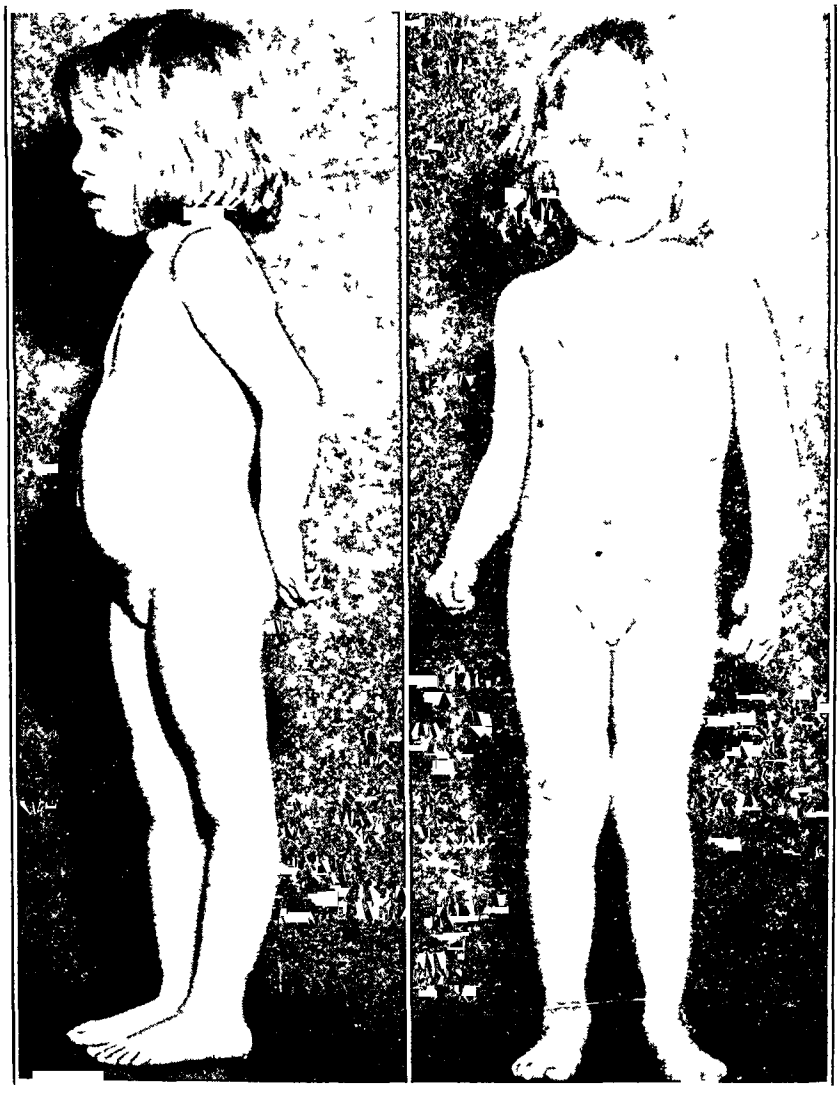
W L is a white man aged 42, born in the United States, married, with one child He works as a supervisor at a paper manufacturing company

He first came under my observation on Sept 20, 1945 He presented weeping, erythematous patches on the glans penis and the shaft Around this area there were numerous areas of telangiectasia said to have followed roentgenologic therapy to the affected areas, with no apparent effect on the original lesions The duration of the eruption was three and one-half years

He failed to respond to ordinary topical remedies such as Aloe vera pulp and ointment, penicillin or various soothing applications prescribed by other dermatologists and by me I finally resorted to a proprietary preparation containing menthol, phenol, camphor, oil of cloves, oil of eucalyptus and lime water in a vanishing cream base of undisclosed formula Since this has been used, the eruption has healed and the patient has had no further trouble The telangiectasia has remained His wife has recently given birth to another child

DISCUSSION

DR JACK WOLF I think that this is an interesting and important case We have seen patients who have been cured, at least temporarily, with radiation, the improvement extending over several years Spontaneous remissions also probably occur in the course of the disease Apparently we do not as yet have the complete picture of the rationale of treatment or of the cure of erythroplasia of Queyrat



DR PERRY M SACHS (by invitation) I should like to know the time relationship between the roentgen treatments and the local therapy

DR GEORGE C ANDREWS I accept the diagnosis in this case, but I think that generally we have to be cautious about accepting the diagnosis of erythroplasia I have in mind a patient whom I saw about two years ago He had had a penile eruption for about two months It was diagnosed as erythroplasia after biopsy by Army physicians On questioning him I found that he had taken sulfadiazine a month or so before the eruption began I told him that I would not accept the diagnosis of erythroplasia and gave him a mild lotion to use, and the balanitis cleared up entirely without any other treatment It is possible that the sulfonamide drugs produce eruptions something like erythroplasia at times We do not know what causes erythroplasia It may come from different things in different persons, so what cures one may not necessarily cure another When carcinoma is definitely present, it is a different matter The whole subject is rather involved

DR NATHAN SOBEL These are interesting cases, and the condition is sometimes difficult to diagnose, as Dr Andrews and others have said When we see

DR JOHN G DOWNING I rubbed my finger nail on the leg After a few minutes a wheal appeared I think that it is a case of urticaria pigmentosa Whether this lesion belongs to the nevoid group, I do not know, other cases of urticaria pigmentosa are so classified

DR BERNARD APPEL, Lynn, Mass The histologic examination should have revealed a typical infiltrate if this were urticaria pigmentosa

Pigmented lesions in a 4 year old girl

Multiple Epidermal Cysts of the Skin Presented by DR MAURICE M TOLMAN, Boston

A 29 year old white nurse, S C, is presented with lesions on the back of her hands of six months' duration She first noted dermatitis venenata on the knuckles of both hands from handling a patient's flowers This was an acute vesicular eruption which healed with mild therapy but left behind small white nodular lesions Four months ago she received roentgen therapy, 500 r in divided doses This caused increased redness and tenderness, there was no improvement in the nodular lesions In the last few weeks they have become somewhat less prominent without further therapy

a patient apparently cured, we are inclined to question the diagnosis I think we must accept the fact that this patient has had erythroplasia and try to give credit where it is due

DR E W ABRAMOWITZ I am sure that Dr Sachs will bring out other important features of this disease Erythroplasia was always considered a serious disease, a precancerosis Radical measures, even including amputation, were discussed I do not recall ever seeing a patient with erythroplasia of the penis in whom cancer of the penis developed I have wondered, therefore, whether radical measures were justified In this case, roentgen rays apparently had no effect except to produce telangiectasia I tried to treat this telangiectasia because in the beginning it seemed to bother the patient He was able to tolerate mild applications of solid carbon dioxide to the telangiectatic area I soon stopped that, however, and used mild boric acid ointment and solution, Aloe vera pulp and then ointment, with little improvement It was not until Dr Cipollaro showed a patient with erythroplasia who had responded to this proprietary preparation that I told my patient about it and suggested its use The patient reported immediate relief I think one can say now that this lesion is healed There has been no activity for several months

I should like to mention another patient, brought to me by a urologist who was considering the possibility of radical measures, there was an erosive lesion of the penis which he thought was cancer I thought it was a drug eruption, as the lesion was typical of a fixed eruption I questioned the man about phenolphthalein, and he denied taking it I was so convinced that he was lying that I went to his house and found feen-a-mint® (laxative containing phenolphthalein) packages and wrappers When he stopped using this the ulcerations disappeared It is not unusual to see lesions in the mouth and on the penis from phenolphthalein, and I have seen a fixed eruption on the penis and in the mouth from veronal® (barbital U S P) and other barbiturates

Erythroplasia—Cured Presented by DR WILBERT SACHS

E G K, a white man aged 45, first noticed a small red papule on the glans penis two and one-half years ago This grew until almost the entire glans was involved There was continuous oozing and slight itching The patient had been treated by several competent dermatologists, all of whom had made a diagnosis of erythroplasia Therapy consisted of local applications of various preparations and the use of roentgen rays, radium and hormone injections, with little or no results

Laboratory examinations, including blood counts, urinalysis and serologic tests, revealed no significant findings Microscopic examination confirmed the diagnosis of erythroplasia

When first seen by us in December 1946, the patient had an erythematous, shiny, oozing patch over most of the glans penis There was no scaling or crusting and no induration The following medication was applied locally, twice a week, for three weeks 0 3 Gm of neoarsphenamine dissolved in 4 cc of distilled water, to which 1 cc of glycerin is added

Oozing and all subjective symptoms disappeared within one week The lesion became crusted, and in the following few weeks the entire process disappeared, leaving no sequelae

Examination reveals an eruption limited to the dorsa of the hands and distributed over the region of the metacarpophalangeal joints The lesions consist of numerous solitary and grouped, milky white, hard nodules of uniform size, they are all 1 to 2 mm in diameter A few exhibit a faint narrow rim of surrounding erythema There is no tenderness now

A specimen was removed for histologic examination, and the diagnosis of "multiple epidermal cysts" was made Results of examinations of the chemical content of the blood, including calcium, cholesterol esters and fatty acids, were normal

DISCUSSION

DR MAURICE M TOLMAN The biopsy specimens were studied in several laboratories, all with the same diagnosis epidermal inclusion cysts, with some changes in the elastic tissue There was no evidence of xanthomatous infiltrate, or of colloid, as far as we know In the literature are reports of 3 such cases Ormsby presented one (Ormsby, O S Bullous Dermatitis [Pemphigus?], ARCH DERMAT & SYPH **28** 246 [Aug] 1933) associated with pemphigus The lesions were in an area of the skin where pemphigoid lesions had healed, leaving these cysts In another instance, cysts came where there was vesiculation following exposure to the sun (Dietel, F *Dermat Wchnschr* **99** 1637, 1934) The third patient had lesions at the sites of vesicles probably from dermatitis venenata We have all seen this occur in epidermolysis bullosa Apparently what takes place is a peculiar reaction to trauma The vesicular lesions heal entirely, and it is in the healing areas that one finds the origin of these epidermal cysts, representing some peculiar response of the tissue The patient is now improving, and we cannot find any reason for it, although she is now pregnant It might be that with the hormonal reaction there may be a nonspecific response She is about 50 per cent better

DR FRANCIS P MCCARTHY The histologic slides showed typical epidermal cysts which are seen so often in the lesions of epidermolysis bullosa One can explain the development of epidermal cysts in the latter disease but not so easily in a vesicular dermatosis on the basis of trauma

Tuberculosis Miliaris Disseminata Faciei Presented by DR FRANCISCO RONCHESE, Providence, R I

Berlock Dermatitis in the Form of a Band Across the Forehead Presented by DR G MARSHALL CRAWFORD, Boston

DISCUSSION

DR MAURICE J STRAUSS, New Haven, Conn I do not recall from the history that a perfume had been used, but, even if it had been, this should not be labeled Berlock dermatitis I would call it pigmentation following dermatitis The term Berlock dermatitis was coined to describe the disease in cases where perfume had been poured on and allowed to run down The word Berlock means pendant It is that particular configuration in which there is evidence of an irritating substance running down in streaks which should be kept as the original concept of Berlock dermatitis

DR WILLIAM B SWARTS, Greenwich, Conn The patient said that he had been employed as a bartender and that the eruption started in September I asked whether he served many Tom Collins drinks during the summer, because the use of lime oil is important The mechanism is the same as Berlock dermatitis except that the essential oil is sprayed over his face A patient of mine with dermatitis venenata of the face made the diagnosis herself and stated that she never got the

DISCUSSION

DR NATHAN SOBEL It is an excellent result

DR JACK WOLF I think that Dr Sachs is to be congratulated It is the first opportunity that we have had of seeing any of the patients whom he has been treating We must take cognizance of the fact that this is not the only case he has shown tonight in which he has obtained a good result but that he is reporting a series of 10 cases, all of which he has followed assiduously Dr Abramowitz' case, which was reported tonight, and the instances of spontaneous improvement that we have seen do not detract in any way from the excellent work which Dr Sachs has done It adds an excellent method of treatment for a disease with which we have had so much trouble

DR MAX SCHEER I wonder whether the patients whom we have seen in this country with the disease which we label erythroplasia are suffering from what the French call erythroplasia According to the French authors, it is not only a precancerosis but it is a cancerosis and it invariably ends with metastasis to the inguinal lymph nodes and death In fact, there have been reports of cases in which the first lesion was a malignant process of the lymph node, followed later on by the erythroplasia of the glans penis In view of the fact that all the French cases have resulted in cancer unless radical treatment was performed and in view of the fact that, according to Dr Sachs, cancer has not developed in a single one of our patients, I wonder whether we are dealing with the same disease or whether it is contact dermatitis or some other kind of dermatitis, as Dr Rosen has suggested

DR PERRY M SACHS (by invitation) Whether or not we are dealing with the erythroplasia described by Queyrat is of secondary import It is erythroplasia as seen and diagnosed by dermatologists in this country and a disease which has proved resistant to all forms of therapy short of heroic measures

DR DAVID BLOOM I should like to ask Dr Sachs how he came to think of this treatment?

DR JACK WOLF Regardless of whether or not we are dealing with the disease which the French authors described, it must be admitted that if Dr Sachs has had such excellent results in the type of disease we see and which we call erythroplasia it is an important contribution to the therapy of a troublesome and obstinate disease We should be able to decide in the near future whether it is the same disease as that described by Queyrat

DR GEORGE C ANDREWS I had 1 case of erythroplasia, clinically typical and diagnosed microscopically by Dr Machacek, in which epithelioma of the penis developed and the patient died of metastasis

DR GEORGE M LEWIS Dr Sachs has observed 10 cases, which is probably 9 more than Queyrat had Why should we necessarily perpetuate Queyrat's conception unless it is the same as ours? I would support Dr Sachs's opinion over that of any of the foreign observers His cases are those in which we are interested It may be a different disease from the one described abroad, but it is the one that we see Furthermore, I think his treatment has been effective, and until this time our treatment has been poor Dr Sachs deserves a great deal of credit, obviously, he has controlled his work and has tried a great many remedies It is not something he thought of last week—he has been at it for a long time I think it is good work, he has not found the cause, but that is not always essential There are many diseases in which treatment is effective although the cause is unknown

eruption until the oil that caused the dermatitis was carried by the effervescent soda water to her face Wiley Sams (ARCH DERMAT & SYPH **44** 571, 1941) reported a case of dermatitis based on the photodynamic action of lime oil

DR JOHN G DOWNING This patient has used nose drops which may have contained silver nitrate Silver nitrate is precipitated rapidly by sun I have seen cases in Florida similar to these after exposure to the sun

DR JOSEPH GOODMAN The patient used a silver salt eighteen years ago for gonorrhea

DR WALTER F LEVER The histologic sections show no evidence of argyria If the pronounced darkening of this patient's skin were due to argyria, one should be able to see silver granules in the sections even without resort to dark field illumination There is considerable increase of melanin in the basal layer and an abundance of melanin-laden chromatophores in the upper part of the corium I regard this case, from the histologic point of view, as one of hyperpigmentation

DR JOHN G DOWNING These patients always exhibit pronounced pigmentation if they are exposed to excessive sunlight Argyria will increase this tendency

DR WILLIAM R HILL I was not impressed with the possibility of argyria, although I did not examine the patient's nails and conjunctivas I agree with Dr Lever histologically, there was too much pigment to suggest argyria Such pigment is found around the sweat glands

DR BERNARD APPEL, Lynn, Mass I was impressed not only by the streak across the forehead that resembled hat band dermatitis but also by the discoloration of the face and neck Melanosis of Riehl should be considered In questioning this man about his diet, I found that he practically never ate any fresh vegetables or fruits I think that there is a possibility of this being the dietary deficiency type of pigmentation which Riehl originally described This is also consistent with the microscopic picture

DR G MARSHALL CRAWFORD By common usage, I think that the term Berlock dermatitis has come to represent almost any bizarre pigmentary deposit caused by photosensitizing agents on the skin It is difficult to see how such a sharply defined rectangular patch could be created without a pattern contact such as a hat band The dye therein, or tanning chemicals, might be incriminated

A Case for Diagnosis (Bacterid?) Presented by DR JOSEPH GOODMAN, Boston

Mycosis Fungoides in a 56 Year Old Woman Presented by DR MAURICE M TOLMAN, Boston

Mycosis Fungoides in a 46 Year Old Man Presented by DR MILDRED L RYAN, Brockton, Mass

DISCUSSION OF CASES OF MYCOSIS FUNGOIDES

DR MAURICE J STRAUSS, New Haven, Conn The woman has changes on her tongue Dr McCarthy pointed them out and said that they were lesions of mycosis fungoides, he had seen a similar case I have never before observed this and wonder whether it would be possible to have a biopsy done to prove it

DR FRANCIS P MCCARTHY Textbooks on dermatology and oral medicine show plates of tongue lesions in mycosis fungoides About twenty years ago I saw a tongue which presented lesions of mycosis fungoides, somewhat like those on this woman's tongue The lesions were raised and nodular, the largest was 0 5 by

DR JACK WOLF Dr Sachs says that his therapy produces an adherent crust which remains for a long time Does he think, then, that we can achieve more rapidly the same type of crust and destruction by desiccation with the high frequency current or by the use of acids such as trichloroacetic acid? Is there any essential difference?

DR FRED WISE I am in complete accord with what Dr Lewis has said, but I think it would be not only desirable but necessary for the author to state that he is not sure he is dealing with the identical disease described by Queyrat American readers regard the term erythroplasia as meaning erythroplasia of Queyrat, and I suggest a notation to the effect that Dr Sachs is not sure he is dealing with that entity but that he is dealing with a disease similar in appearance and in chronicity, which, however, does not eventuate in cancer

DR DAVID BLOOM Neoarsphenamine dissolved in distilled water and then in glycerin, in 10 per cent concentration, has been used for several decades in the treatment of Vincent's infection of the mouth It is logical to assume that the beneficial effect obtained by Dr Sachs in his cases of erythroplasia is due to the effect on spirochetes or bacteria In these cases, therefore, there should be bacteriologic examination, irrespective of their duration

DR GEORGE M LEWIS I wonder if some of the malignant processes that supervene in these cases are the result of the treatment administered, such as desiccation or the use of pastes and irritant remedies In your opinion, Dr Sachs, is treatment ever responsible for malignant changes?

DR WILBERT SACHS The disease treated in this case, and in the other 9 cases reported in our paper, is the same as that described by Queyrat The French authors believe that in most of the cases the lesions become malignant The experience in our cases is not in accord with this view There have been only 2 cases reported in the American literature in which malignant changes developed In 1 the original diagnosis was questioned, in the other, the lesion was basal cell epithelioma and not erythroplasia Dr Andrews' case would make a third There are cases in which the lesion has all the clinical features of erythroplasia but microscopically proves to be either basal cell epithelioma or Bowen's disease However, as Dr Lewis suggests, it is always possible for a malignant process to follow long-continued treatment which includes such heroic measures as those employed in an endeavor to control erythroplasia In reply to Dr Wolf's question, desiccation and escharotic preparations have produced good results in some cases, but with sequelae and disfigurement These have not followed the treatment we are reporting

A Case for Diagnosis (Poikiloderma Atrophicans Vasculare?) Presented by DR DAVID BLOOM

R C, a white woman aged 47, complained of an eruption on the palms and soles of eight months' duration and of a generalized eruption of five months' duration The family history and the past history was essentially irrelevant The patient seems to be in fairly good general health

The plantar surfaces of the feet, and particularly of the heels, showed pronounced hyperkeratosis The dorsal surfaces of the feet and toes were slightly scaly and mildly erythematous The palms were dry and scaly and showed accentuation of the natural lines The backs of the hands and fingers were similarly affected, but to a lower degree The anterior and lateral aspects of the thighs and hips showed erythema, scaling, wrinkling and mottled hyperpigmentation The

3 0 cm One on the dorsum of the tongue was white on top, suggesting a secondary leukoplakic reaction The rest of the oral cavity was free of lesions

DR B J KENNEDY, Boston (by invitation) The woman was given urethane because of reports describing its use in leukemia and a few isolated carcinomas Urethane is called ethyl carbamate and is an ancient anesthetic for animals Haddon and Sexton (Influence of Urethane on Experimental Tumors, *Nature,* London **500** 157, 1946) found that phenyl carbamate and phenylurethane produced regression of mammary carcinoma in mice and Walker carcinoma in rats This led to investigation with urethane which produced the greatest effect, especially in the carcinomas There were scarring and decrease in the mitoses in the cells Another group from the same hospital began using urethane in human beings (Paterson, E , Haddow, A , Ap Thomas, I , and Watkinson, J M *Lancet* **1** 677, 1946) They tried it in 19 patients with myeloid leukemia, 13 with lymphatic leukemia and 13 with various types of carcinoma Among the last group only 4 (including patients with Hodgkin's disease and a salivary gland carcinoma) showed some regression of the tumor while the others had but little response The reaction in the patients with myeloid leukemia was striking In nineteen to forty-seven days the urethane produced a reduction in the white cell count of 20,000 or more cells It was found that this reduction of the white cells was chiefly in the neutrophils The hemoglobin did not seem to be affected, or the red cell count, and when the patients were given 100 Gm or more of the drug the hemoglobin rose an average of 27 per cent The patients with lymphatic leukemia showed a similar response but not as striking as did those with myeloid leukemia It was concluded that the urethane treatment of leukemia may be comparable to roentgen therapy The rise in hemoglobin, decrease in white cell count and reappearance of normal differential counts all followed the same pattern as would be expected with roentgen treatment Because of this and the close relation of mycosis fungoides to lymphomatous disease, urethane was given to this patient My co-workers and I plan to give it to a large series of patients to determine whether or not it is a drug that should be used in these cases This patient has been treated for almost two weeks, and the only response so far is perhaps some drying of the skin

DR JACOB H SWARTZ Have you read any reports citing granulocytopenia as a complication of this treatment?

DR B J KENNEDY, Boston (by invitation) Leukopenia develops in many of the patients If this reaction occurs, the drug must be withdrawn I have not heard of the occurrence of granulocytopenia

DR ARTHUR M SIMMONS What is the method of administration and dosage?

DR B J KENNEDY, Boston (by invitation) It is given orally, 1 Gm four times a day At present I do not believe that there is any definite dose that one can adhere to, we expect to try to increase the amount

Extensive Nevus Pilosus et Pigmentosus (von Recklinghausen's Disease?) Presented by DR G MARSHALL CRAWFORD, Boston

A Case for Diagnosis (Lupus Erythematosus? Tuberculosis Luposa?) Presented by DR ROBERT H GOLDFARB, Boston

Telangiectasia, Essential, Limited to Calves Presented by DR MAURICE M TOLMAN, Boston

C B , a 32 year old white housewife, is shown with changes on the backs of her legs which have been present for three and one-half years The patient first

region of the hypochondria and the under surfaces of the breasts showed a definite picture of poikiloderma, consisting of reticulated pigmentation, telangiectasia and atrophy There was decided wrinkling of the upper parts of the breasts and reticulated hyperpigmentation and atrophy in both axillas The lower part of the back, inner aspect of the upper extremities and back of the neck were scaly and erythematous The axillary lymph glands were enlarged The upper eyelids showed erythema and edema, which had been present for the past two months

Laboratory examinations, including urinalysis, serologic tests of the blood for syphilis and complete and differential blood counts, gave essentially normal results

Biopsies of material taken from the skin under the breast and from the thigh showed features of poikiloderma

DISCUSSION

Dr Nathan Sobel The patient definitely had poikiloderma in the areas over the lower part of the breasts and atrophy over extensive areas elsewhere, but I am puzzled by the hyperkeratosis of the palms and soles and do not believe that is often found in cases of poikiloderma

Dr E W Abramowitz I have the same difficulty in reconciling the hyperkeratosis of the palms and soles I do not recall having seen it in cases of poikiloderma It is a question whether some other disease should be considered or whether further observation is necessary before the case is labeled poikiloderma

Dr George C Andrews The case reminded me of the cases of dyspituitarism with poikiloderma-like changes, reported by Bruno Bloch I think that the woman has endocrine disease A basal metabolism test, roentgenograms of the sella turcica, an encephalogram and various other tests are indicated In many cases of Cushing's basophilism the disease is related not to the pituitary but to the adrenal glands, so this case should be studied from that angle I am wondering whether the hyperkeratosis of the soles could be related to localized myxedema in which there is a great deal of lymph stasis that produces verrucous changes

Dr E W Abramowitz Dr Andrews brought up a point which might still point to the pituitary The patient may have keratoderma climactericum

Dr Fred Wise I agree with those who believe that the eruption is caused by a polyglandular disturbance similar to Cushing's syndrome, in which almost invariably telangiectasia and pigmentation of the lower portion of the breasts are present Poikiloderma is merely a symptom, whereas poikiloderma vasculare atrophicans is a definite clinical entity, as described by Jacobi This patient has a poikilodermatous skin associated with polyglandular disturbances, but the condition should not be described as a case of Jacobi's disease because, as the name suggests, that has a variegated appearance It would be better to describe it under a name which at least suggests pituitary basophilism or Cushing's syndrome

Dr David Bloom I realize the difficulty in diagnosing this condition Besides the poikiloderma-like eruption and the scaly plaques, the patient shows extensive keratosis of the palms and soles, which would fit in with psoriasis or keratoderma climactericum One finds erythema of the eyelids in poikilodermatomyositis, but in this patient it developed only one month ago, late in the course of the disease I am inclined to agree with Dr Andrews and Dr Wise in regard to a thorough study of the patient in order to eliminate an endocrine condition such as Cushing's pituitary basophilism A definite diagnosis, of course, cannot be made at present

A Case for Diagnosis (Leukonychia and Hyperpigmentation of Gums and Lips) Presented by Dr E W Abramowitz

noted these lesions on both her thighs and her legs Those on the thighs have gradually cleared, but lesions have persisted on the calves She stated that she bruises too easily but gives no history of epistaxis It was stated that some lesions bled on several occasions following minor trauma This woman was extremely nervous and suffered from melancholia during her only pregnancy five years ago, she has taken sedatives at night since that time There has been considerable menstrual irregularity The general medical history was otherwise noncontributory There was no history of similar lesions or of epistaxis in the family

Examination revealed a profusion of dilated blood vessels restricted to the lower third of each calf Most of these are of telangiectatic caliber but some are slightly larger They gradually fade out on the middle portion of the calves and on the sides of the legs

The prothrombin time (clotting time) of the blood plasma was found to be 20 seconds The sedimentation rate of the blood was 3 mm in 1 hour The cellular elements of the blood were normal A specimen removed for histologic examination revealed only atrophy of the epidermis and fibrosis of the corium One small area was treated by electrodesiccation with some resultant diminution in telangiectasia

DISCUSSION

DR WALTER F LEVER This disorder is really not too rare It was first described in the American literature by Stokes (*Am J M Sc* **149** 669, 1915) under the name of generalized telangiectasia and was thought to be associated with syphilis Among subsequently reported cases some patients had syphilis, but in most instances they did not It was also found that the disorder was not necessarily generalized, in patients with localized distribution the lower legs are most commonly affected The telangiectatic vessels are dilated venules They are dilated because their innervation is defunct Recently, in a patient with telangiectasia of the lower legs, I injected both a vasoconstricting and a vasodilatory drug intradermally, following Perutz' directions (*Arch f Dermat u Syph* **148** 313, 1924-1925) Intradermal injection of 0 1 cc of a 10 per cent solution of caffeine sodium benzoate caused the skin around the site of injection to become bright red, but the affected vessels did not change their size Similarly, 0 1 cc of a 1 1,000,000 solution of epinephrine injected intradermally caused blanching of the skin around the site of injection, but did not affect the telangiectatic vessels The disorder is harmless as such, but it is advisable to examine such patients for syphilis

Oct 14, 1947

Generalized Progressive Scleroderma and Dermatomyositis Improved with Diphenhydramine (Benadryl®) Presented by Dr Maurice J Costello

J F, a married woman aged 42, was presented before this Society on Oct 10, 1944, with a generalized progressive scleroderma and dermatomyositis associated with acrosclerosis and Raynaud's phenomenon

Since March 1946 she has been given 400 mg of diphenhydramine daily, with remarkable improvement, there is increased mobility of the joints and softening of the boardlike infiltrations and the dyspnea, wheezing, dysphagia and loss of muscle power have been relieved to a remarkable extent The results have been so spectacular that the only abnormality remaining is the irreversible contraction of the fourth and fifth fingers

DISCUSSION

Dr David Bloom I believe that diphenhydramine in such large doses should be given to a patient only when he is hospitalized and under close observation I saw a patient who had received 150 mg of the drug daily over a period of several weeks suddenly collapse with a sensation of constriction in the chest and numbness of the upper extremities

Dr Maurice J Costello The patient's condition was so advanced that she had not only severe edematous thickening of the skin and lack of mobility of the joints but also dysphagia and dyspnea Her general practitioner gave her diphenhydramine mainly to relieve what he considered asthmatic symptoms, and she has taken 400 mg every day for a year and a half I presented this patient before this society in 1944, and the change since has been nothing short of remarkable This patient had received dihydrotachysterol (hytacherol®) with no benefit

Dr Samuel M Peck When dihydrotachysterol works, it is only on the edematous part If diphenhydramine works, it is something entirely different I think that I shall try iontophoresis with pyribenzamine,® as I am doing with neurodermatitis, especially of the hands I know that the drug stays in the tissues for weeks

Dr Anthony C Cipollaro Does diphenhydramine produce vasodilatation?

Dr Maurice J Costello I believe so, because the patient has been free of the blanching of the fingers associated with Raynaud's phenomena I might add that the only other case I have seen recently that approaches this in therapeutic result was that of a patient whom I sent from Lenox Hill Hospital to Bellevue Hospital, who received a high protein diet with large doses of a protein hydrolysate (amigen®) Graphic studies were taken of the improved mobility of the joints and the skin overlying them

Dr Samuel M Peck Was there a reversal of result with primary lesions again with a violet ring?

Dr Maurice J Costello No I have never seen improvement from dihydrotachysterol that was permanent The diphenhydramine was discontinued in this case for three weeks, with recurrence of symptoms

York State J Med 46 2147 [Oct 1] 1946) who used with success in dyskeratotic dermatoses triolein ozonide, which is formed in olive oil on ozonization

DR NEVILLE KIRSCH, Hartford, Conn (by invitation) Sharlit has used ozonides in oil By rubbing in the oil four times daily his patients succeeded in eliminating keratotic lesions It has also been employed by MacKee The product may be obtained from G F Harvey & Company of Saratoga Springs, N Y, and must be refrigerated Twenty per cent of the ozonide mixture is incorporated in an appropriate base and rubbed in four times a day for six to eight weeks

DR WALTER F LEVER, Boston I have had no experience with ozonides, but I suggest treatment with 2,3-dimercaptopropanol (BAL) Since in this patient the arsenic preparation was given only two years ago, there may still be some arsenic remaining in her tissues, and it might continue to form keratoses BAL is effective in liberating organic arsenic from tissue

Dermatitis Herpetiformis (Contact Dermatitis from Rubber?) Presented by DR CARL A DAHLEN, Boston

T B, a 23 year old white girl, displayed an eruption of two years' duration, affecting the forearms, scalp, trunk and buttocks The first lesions appeared on the forearms in the form of vesicles At some later date the scalp became affected Lesions developed on the back and buttocks about a year ago Itching and burning have been severe, the patient claimed to be exhausted at times from these symptoms

On examination this young woman revealed a symmetric eruption affecting the scalp, forehead, elbows, dorsal aspects of the forearms, shoulders, scapular areas, lower part of the trunk and buttocks On the back is a transverse band of clear skin at the level between the brassiere and girdle areas The primary lesions are grouped vesicles and papules with crusted excoriations and pigmented scars These changes are most pronounced on the elbows, shoulders and hips The lines demarcating the clear zone across the back are rather sharp Both the upper part of the back and the girdle area below reveal a mild diffuse erythema, and there is a minimal amount of fine branny scaling on these regions On the upper part of the back there are three moderately distinct rectangular patches, which stand out from the previously defined changes One is seated transversely across the middle part of the back, the other two are vertically parallel to each other on the midscapular regions These patches are approximately 5 by 15 cm in size and display a perceptible thickening with more scaling than the surrounding skin

Results of an examination of the urine and a hemogram were normal Treatment included use of diphenhydramine hydrochloride (benadryl®) 0 05 Gm three times daily for five weeks, followed by sulfapyridine, 0 5 Gm, twice daily for two weeks Two suberythema doses of ultraviolet rays were given prior to the sulfonamide drugs There had been temporary improvement from these measures

DISCUSSION

DR FRANCIS M THURMON, Boston I agree with the diagnosis of dermatitis herpetiformis If sulfapyridine were used in larger dosage, it would be more effective

DR GEORGE SCHWARTZ, Boston I disagree This is contact dermatitis due to rubber inserts in her brassiere and girdle I had the patient put on her girdle, and the lower portion of the eruption formed a complete outline of the garment The dermatitis is now becoming generalized

A Case for Diagnosis (Lymphatic Leukemia Following Vaccination Against Smallpox?) Presented by DR DAVID BLOOM

J H, a man aged 80, was referred to me in September 1947 by Dr H Wolf because of a tumor which had developed in the area of smallpox vaccination five months previously The patient also suffers from generalized pruritus

On the external aspect of the right arm there was a walnut-sized, erythematous, raised and indurated, globular tumor, firm in consistency and with borders infiltrating the surrounding skin in an ill defined manner In the vicinity of the tumor there were a number of erythematous, pea-sized and excoriated papules In addition to this lesion which caused severe pruritus, there were excoriated lesions on the forearms, the lumbosacral region and the legs In the axillas slightly enlarged nodes were palpable

Biopsy of the tumor on the arm revealed a "nonspecific type of granuloma" A blood count on two occasions showed a normal red cell count, but a white cell count of 13,600 on one occasion and 16,900 on another The differential count, in addition to 3 per cent blasts, showed 58 per cent lymphocytes and 35 per cent polymorphonuclear leukocytes and on another occasion 76 per cent lymphocytes

The patient is in good general health except for the generalized pruritus which disturbs his sleep The lesion on the right arm has diminished in size after several treatments with filtered roentgen rays

DISCUSSION

DR WILBERT SACHS The microscopic section that I examined was from the arm and suggested a nonspecific granuloma The characteristic picture of lymphatic leukemia, which undoubtedly should be present in a lesion of this size, was not seen If the patient has lymphatic leukemia, it is unrelated to the lesion on the arm

DR SAMUEL M PECK A number of years ago I thought that it would be interesting to take cases of chronic lymphatic leukemia, acute leukemia and diseases like purpura hemorrhagica and do trichophytin, tuberculin and venom tests and study the histologic appearance, to see how a known blood picture would influence a histologic reaction with which I was familiar I found nothing very striking

DR WILBERT SACHS Instead of a leukemia infiltration, one finds a leukemid type of reaction, and this is nonspecific

DR ANTHONY C CIPOLLARO Does the patient have leukemia in the first place, and did vaccination have anything to do with it if he has? There has not been enough evidence to indicate a relation between smallpox vaccination and leukemia

DR DAVID BLOOM The diagnosis of leukemia was suggested by the increase in the white blood cells, the high lymphocyte count and the presence of blasts This opinion was shared by the hematologist, who advised sternal puncture In spite of the absence of a confirmatory histologic report, this diagnosis is most probably correct

Acrodermatitis Pustulosa Perstans Presented by DR WILBERT SACHS

Lymphoblastoma, Clinically Poikiloderma, Histologically Mycosis Fungoides Presented by DR JACK WOLF

DR WALTER F LEVER, Boston That would not explain the lesions on the forehead and scalp I agree with the presenter's diagnosis of dermatitis herpetiformis and would suggest that sulfapyridine be given in larger amounts I have observed a case in which there was no response until 6 Gm a day were given The patient has been taking that dose for six months, and it controls the eruption

DR JOSEPH GOODMAN, Boston What blood level of sulfapyridine was reached with that amount?

DR WALTER F LEVER, Boston I have done no determinations of the blood level

DR WILLIAM P BOARDMAN, Boston The patient told me that she was just as uncomfortable while taking sulfapyridine If the sulfonamide drugs are not well tolerated or are ineffective, why not try potassium arsenite solution (Fowler's solution) which has long been known to be effective in dermatitis herpetiformis?

DR JOSEPH GOODMAN, Boston The use of sulfapyridine in dermatitis herpetiformis interested me in relation to a patient I treated recently, starting as Dr Lever did and increasing to a maximum dose of 6 Gm a day My patient had typical dermatitis herpetiformis The drug was given in gradually increasing amounts over a period of three months At the end of that time she took 6 Gm daily for two and one-half weeks The blood level was slightly over 7 mg per hundred cubic centimeters, an adequate level of sulfapyridine The dermatitis did not improve more than 20 per cent It was a question whether 8 Gm a day would be effective The blood level seemed adequate, and I was a little uneasy about the situation as it was I wonder how many failures with sulfapyridine have been seen by the members of this society, with doses of 3 to 5 Gm daily as a maximum

DR OSCAR GILJE, Oslo, Norway (by invitation) I would like to hear about the treatment of dermatitis herpetiformis with diphenhydramine hydrochloride (benadryl®) Two patients in Norway whom I treated with benadryl® were relieved In 1 of the cases the disease was of six years' duration and in the other one-half year When benadryl® therapy was stopped, the itching became worse, the patients improved on resuming treatment with benadryl®

DR BERNARD APPEL, Lynn, Mass I questioned this patient about her reaction to benadryl® and she told me that it did not help her pruritus It did procure a good night's sleep and made her feel more relaxed but apparently did not relieve the itching I would agree with the diagnosis of dermatitis venenata due to rubber in the clothing The entire picture is consistent with that diagnosis, not only because of the definite, clear, smooth, symmetric pattern which corresponds to the articles of clothing worn that contain rubber but also because the rest of the eruption is consistent with it Contact dermatitis due to rubber from articles of clothing may produce generalized eruptions The presence of vesicles certainly does not contradict the diagnosis of contact dermatitis

DR JACOB H SWARTZ, Boston How often do you see clusters of scars in dermatitis from rubber?

DR BERNARD APPEL, Lynn, Mass Consequent reactions like crusting, follicular involvement, pigmentation and all the so-called "id" type of lesions depend, first, on the duration and, second, on the particular patient's sensitivity and intensity of reaction

A Case for Diagnosis (Lichen Planus? Psoriasis?) Presented by Dr Nathan Sobel

G F, a woman aged 52, was first seen at the Skin and Cancer Unit of the New York Post-Graduate Medical School and Hospital on Oct 16, 1947 with an eruption of six weeks' duration

On the right upper eyelid there is a well defined, oval plaque which shows an erythematous, raised border and depressed, crusted center On the buccal mucosa there are divided plaques with reddish borders The entire scalp shows thickening of the skin, erythema and scaling There are erythematous, superficial, slightly scaly, well defined round plaques on the chest and on the upper part of the back and arms on the left On the extensor aspect of the thighs and inner aspect of the right thigh there are some purplish lichenified plaques There are erythema and fissuring in the genitocrural creases All the finger nails show onycholysis The nails of both big toes are greatly discolored, thickened and loose

The only laboratory report available to date is on the Wassermann reaction of the blood, which was negative

DISCUSSION

Dr David Bloom The patient presents lesions on the lower extremities and on the buccal mucosa which look like lichen planus and an eruption of the scalp and changes in the nails suggesting psoriasis This combination of psoriasis and lichen planus has been reported on several occasions

Dr Nathan Sobel I think that the lesion on the left buccal mucosa is probably a bullous lesion of lichen planus I have also previously seen lichen planus on the scalp To settle the question, biopsy would be necessary I think the changes in the nails are psoriatic

Note.—It was reported at the succeeding meeting, in November, that biopsies, one from the leg and another from the neck adjacent to the scalp, both showed mycosis fungoides

A Case for Diagnosis (Peculiar Eruption of Granuloma Annulare?) Presented by Dr David Bloom

M McH, a woman aged 41, registered at the Skin and Cancer Unit of the New York Post-Graduate Medical School and Hospital in October 1947, complaining of an eruption of one year's duration The eruption started first on the elbows, later it appeared on the lower extremities, and in the past three months it has involved the wrists There are no subjective symptoms

On the posterior and internal aspects of both lower extremities, extending as far as the middle of the legs, there is a profuse eruption of bluish-brownish, flat lesions, from the size of a lentil to that of a pea, some of which feel somewhat infiltrated A similar but less profuse eruption is seen on the flexor and internal aspects of both upper extremities Over both knees and elbows there are pink to skin-colored, raised, indurated papules Similar lesions are seen over the external malleolus of the left leg There are a moderate number of raised, dark red, firm, globular and elongated lesions on the flexor aspect of both wrists, extending to the forearm Over the sacrum, similar lesions form an irregularly shaped plaque

Microscopic examination of lesions from the wrist, elbow and thigh all showed the structure of granuloma annulare As reported by Dr Charles F Sims, the epidermis was thin, and the corium beneath showed basophilic degeneration In the upper and middle parts of the cutis were areas of granular degeneration surrounded by small, round and wandering connective tissue cells, epithelioid and giant cells The infiltrate took an arciform arrangement in many areas

DR JOSEPH GOODMAN, Boston I think that we are going far afield when we call this a contact dermatitis Let us assume, with Dr Schwartz, that this eruption corresponds exactly to the rubberized areas of the girdle It has spread to the forehead, scalp and elbows In contact dermatitis severe enough to produce a widespread eruption one must also expect a local extension I cannot conceive of a dermatitis of this sort spreading so widely without becoming generalized on the trunk I am sure that if these lesions were not in the area touched by her girdle, there would be no doubt about dermatitis herpetiformis

DR JOHN G DOWNING, Boston Two months ago this girl presented a classic picture of dermatitis herpetiformis, with the characteristic symptom of burning She showed grouping, pigmentation and atrophic scarring Today there is unquestionably a superimposed contact dermatitis which might be due to the elastic in the straps of her brassiere

DR CARL A DAHLEN, Boston There was considerable relief from treatment with benadryl,® but the patient failed to return The next time we saw her she had a recurrence I decided to give sulfapyridine, and it was prescribed in a dose of 0 5 Gm twice a day, but she still did not report back as instructed If she were cooperative, I might have obtained better results by increasing the sulfapyridine

DR FRANCIS P MCCARTHY, Boston This girl had a very interesting tongue She showed linear filiform papillae along the margins and beneath these areas were tufts of white hairlike papillae I made a diagnosis of depigmented congenital defect of the filiform papillae Some textbooks indicate that there are oral lesions in dermatitis herpetiformis I have never observed them, although I have been searching for years Has anyone here seen lesions in the mouth in dermatitis herpetiformis?

DR FRANCIS M THURMON, Boston I have seen 2 cases, one was shown to me in Chicago and the other was presented by me at a meeting of this Society

DR WALTER F LEVER, Boston I have seen 1 patient His eruption responded well to the usual doses of sulfapyridine, 2 to 3 Gm a day There was no doubt about the diagnosis

Lichen Planus of the Eyelids and Buccal Mucous Membranes Presented by DR WILLIAM J MACDONALD, Boston

Lichen Sclerosus et Atrophicus (Generalized) Presented by DR JOSEPH GOODMAN, Boston

DISCUSSION

DR JOSEPH GOODMAN, Boston This 43 year old woman has been followed in the clinic for six months At the start there was a hyperkeratotic follicular eruption characterized by small horny spicules She had alopecia when first seen, and this has extended since then It was thought at first that this was a vitamin A deficiency, but the vitamin A level and carotene level were normal In spite of that she received 200,000 units of vitamin A daily for a period of two months, during which time the eruption became worse The patient was then admitted to the hospital, and a biopsy was performed on the scalp lesions Those on the arms began to look like lichen planus and others have too, but at the same time many of the horny spicules seen when she was first observed in the clinic have persisted The picture presented today corresponds closely to the description of the disease called "lichen planopilaris" by Sachs and De Oreo (ARCH DERMAT & SYPH **45** 1081 [June] 1942)

DR WILBERT SACHS I should consider other possibilities in preference to granuloma annulare Before accepting this diagnosis, I should like to study the microscopic sections Although numerous giant cells may be found as a rule they are not a feature of granuloma annulare

DISCUSSION

DR THOMAS N GRAHAM I think that the individual papules on the dorsum of the right hand look like the lesions usually observed in granuloma annulare, although they are not in annular formation However, the lesions on the forearm do not resemble that dermatosis clinically but, rather, suggest lichen planus

DR FRANK E CORMIA (by invitation) Dr Peck and I had the same opinion—that, clinically at least, the lesions are suggestive of amyloidosis

DR SAMUEL M PECK What struck me was the two distinct types of lesions The first was the skin-colored lesions on the back of the hands and even on the elbows which I should not hesitate to call granuloma annulare Then I saw another type, peculiar brownish-bluish lesions which made me think of amyloid disease but the fact that the microscopic appearance of three lesions was the same makes me doubt that we are dealing with amyloidosis The peculiar cases shown at the meeting of the American Academy of Dermatology and Syphilology in Chicago turned out to be extracellular cholesterosis I should certainly like to see studies made along that line

DR ISADORE ROSEN The clinical features suggest the lichenoid type of sarcoid rather than granuloma annulare

DR NATHAN SOBEL One of the thoughts that first occurred to me was possible amyloidosis, but against that is the complete absence of itching, which is certainly a distinctive feature of amyloidosis The lesions around the anterior surface of the wrist are skin colored and hard and could fit into the picture of granuloma annulare The other lesions are not characteristic and look almost like lichen planus at a casual glance I think it best to include all the lesions as granuloma annulare

DR MAURICE J COSTELLO This case impressed me also as one of lichenoid sarcoid I should like to see the results of tuberculin tests and roentgen examination of the chest I think that it is true that granuloma annulare responds to roentgen rays

DR DAVID BLOOM The biopsy report was surprising to all of us who had observed this case and did not think of the diagnosis of granuloma annulare Although I have seen atypical cases on several occasions, particularly of disseminated granuloma annulare in children, I have never seen a case similar to this one The patient will be studied more thoroughly

Darier's Disease Presented by DR NATHAN SOBEL

A Case for Diagnosis (Keratoses? Lupus Erythematosus?) Presented by DR ANTHONY C CIPOLLARO

Mycosis Fungoides Presented by DR MAX SCHEER

Parapsoriasis Guttata Presented by DR MAX SCHEER

Hypersensitivity to Cinnabar in a Tattoo Presented by DR JACK WOLF

Multiple Superficial Basal Cell Epithelioma with Arsenical Keratoses Presented by DR JACK WOLF

Multiple Epidermal Cysts of the Skin Presented by DR F RONCHESE, Providence, R I

A 14 year old white school girl, G deB , American-born of Portuguese parents, is presented with lesions which have been present on her face since birth They have not been observed to change appreciably with the passage of time She had

Fig 1—Multiple epidermal cysts of the skin The face of a 14 year old girl studded with milia, a few isolated lesions of keratosis pilaris and erythema

no hair anywhere until the age of 3 years, at that time a little began to appear on her scalp, and it developed slowly thereafter There were no eyebrows until the past few years, and no hair has developed elsewhere The patient has always been in good health There is no history of similar disturbances among other members of the family Negro ancestry was denied The patient seemed of normal intellect and was progressing well at school

NEW ENGLAND DERMATOLOGICAL SOCIETY

Bernard Appel, M D, President

G Marshall Crawford, M D, Secretary

Boston, Feb 12, 1947

Incontinentia Pigmenti Presented by DR G MARSHALL CRAWFORD, Boston, and DR C R DAMIANI, Worcester, Mass

A 4 year old white girl of American birth, P W, is presented with an eruption on the trunk and upper part of the thighs present since early infancy At about the age of 3 months, pigmented streaks were seen on the back of the upper part of the thighs These gradually became more pronounced and extended upward, eventually involving the back and abdomen A year ago, when the patient had measles, the pigmented areas were observed to become scarlet, after recovery the areas gradually returned to the previous shade of brown No other member of the family has been affected by any similar condition There was no history of congenital anomalies, the child had a normal developmental history and was mentally alert

Examination reveals a pigmentary disturbance approximating the "bathing suit" distribution The upper limits are the xiphoid level anteriorly, the axillas laterally and the inferior edges of the scapulas on the back It extends downward over the trunk and across the hips and buttocks to about the junction of the upper and middle thirds of the thighs The lesions consist of symmetrically arranged striate and whorl-like pigmentary deposits of medium brown The majority of them are linear, and their length varies from 1 to 3 cm, most lesions are from 3 to 5 mm in width They are arranged in parallel fashion corresponding roughly to the cleavage lines of the metameric segments

A biopsy was performed, and histologic observations were reported as "consistent with lentigo"

DISCUSSION

DR WALTER F LEVER The histologic picture bears out the diagnosis of incontinentia pigmenti Considerable amounts of melanin were present in the upper part of the corium, whereas melanin in the basal layer was not increased Other forms of hyperpigmentation usually show increased pigmentation both in the basal layer and in the upper part of the corium

DR WILLIAM R HILL I think that Sulzberger and Bloch reported a case of incontinentia pigmenti and concluded that it was a familial disorder This case is not familial

DR WALTER F LEVER In several of the reported cases other abnormalities, such as ectodermal defects, were present in the patient as well as in members of the patient's family There is, however, only one report, that of Naegeli (cited by Sulzberger, M B, ARCH DERMAT & SYPH **38** 57, 1938), concerning the familial occurrence of incontinentia pigmenti Thus, the absence of a familial history is not against incontinentia pigmenti

There is a luxuriant growth of kinky hair on the scalp and the facial conformation is Negroid The face is reddish pink The skin thereon appears granular and feels slightly rough It is entirely covered with densely packed miliary lesions of 0 5 to 1 0 mm diameter, these are pearly white and smooth Diascopic examination shows complete blanching of the lesions No telangiectases can be observed The patient's eyebrows are sparse, scaly and also studded with milia The remainder of her skin exhibits no hair The lateral aspects of the arms and thighs reveal a sparse eruption consistent with keratosis pilaris, and a few isolated lesions on the face are similar in type No scars can be found anywhere

The Hinton reaction of the blood was negative Results of examination of the urine were normal A hemogram was normal with the exception of a leukocyte

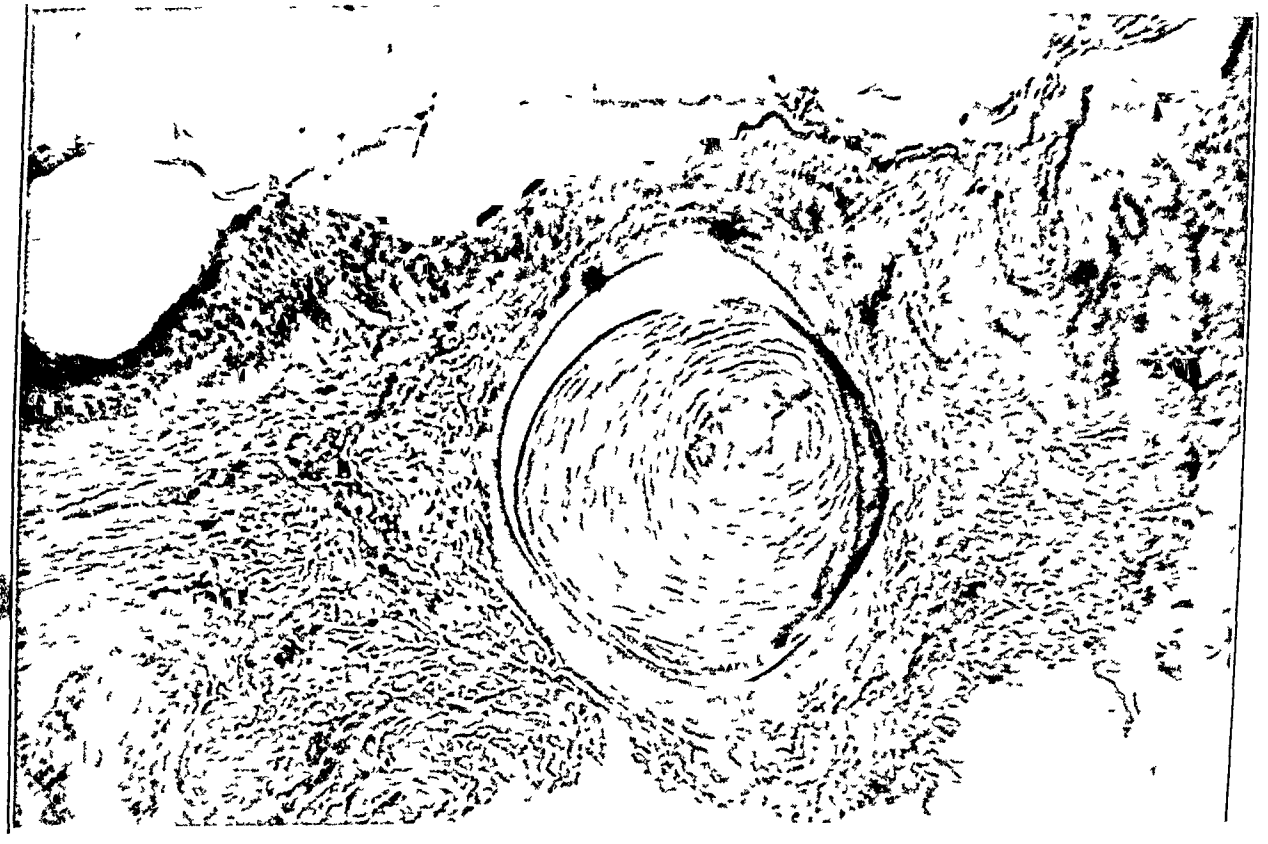

Fig 2—Multiple epidermal cysts of the skin Histologic section showing epithelial cysts

count of 10,750 cells per cubic millimeter The nonprotein nitrogen and glucose content of the blood were normal Histologic examination of a biopsy specimen revealed a moderate degree of hyperkeratosis There were cystic cavities about 0 2 mm in diameter just beneath the epithelium, these were lined with squamous epithelium and filled with a laminated keratotic mass No treatment had been administered until the past two months, during which time the patient has taken 200,000 units of vitamin A daily, there has been no appreciable improvement

DISCUSSION

Dr Jacob H Swartz, Boston Although I am in accord with Dr Ronchese's diagnosis, I should like to point out that the patient had definite hyperkeratotic

DISCUSSION

DR S J ZAKON The internists recognize this as part of the signs and symptoms of the Chvostek Habitus (Chvostek, F Cirrohis of the Liver, *Wien Klin Wchnschr* **35** 381, 1922), in which there are ascites and jaundice, pulsating spider nevi and loss of body, axillary and pubic hair This is usually observed in nonobstructive jaundice

DR HAMILTON MONTGOMERY, Rochester, Minn My co-workers and I have seen a number of pulsating hemangiomas of the skin in patients referred by various internists in our clinic Dr Williams and Dr Snall reported a series of these cases (*Arch Int Med* **62** 872-882 [Nov] 1938) All the phenomena that have just been mentioned are not necessarily present Pulsating hemangiomas are almost invariably associated with cirrhosis of the liver

DR THEODORE CORNBLEET At the Cook County Hospital various clinicians have pointed out for years that there is a lack or sparsity of hair about the male abdomen and chest in the presence of cirrhosis of the liver My associates and I always suspect that there is cirrhosis of the liver in such cases In a number of these patients telangiectases of the chest and upper part of the abdomen and a few of the blood vessel enlargements can be seen, or more often felt, to pulsate We have tried the newer nutritional remedies for cirrhosis of the liver, such as methionine and cysteine Though some of those patients were said to be improved clinically and show better results in tests of hepatic function, I have never seen these angiomas and telangiectases disappear thereby I have seen these lesions regress, however, after parturition There is no doubt that in other cases they may clear spontaneously

A Case for Diagnosis (Lupus Erythematosus, Telangiectatic Type?) Presented by DR CLEVELAND WHITE and (by invitation) DR J L MADURA

Squamous Cell Carcinoma of the Penis Presented by DR M OPPENHEIM and DR D COHEN

Mr C P, a Negro aged 49, has a tumor-like lesion on the penis of four years' duration There is no pain but some tenderness on pressure The lesion is about the size of a half-dollar and is situated on the outside of the prepuce It has an irregular configuration, in some places polycyclic with overhanging margins There are yellowish crusts and scales on the surface When these are removed, pressure on the tumor cause white millet-sized drops to appear The lesion is indurated and of a cartilaginous consistency There is no inflammation Inguinal glands are not enlarged

On the glans penis there are depigmented, depressed, irregular scars with a smooth flat base and a slight hyperpigmentation in the periphery This lesion began as a solid nodule four years ago (1943) and has progressed until the present time In 1943 and in 1917 the patient received treatment for his blood For many years he was a laborer on a railroad, and now he is employed in an ice cream factory. No history of exposure to oil is given

The urine is normal The blood cell count is normal The Kahn reaction of the blood was negative on April 19, 1947, and on April 20, 1947

Biopsy of the skin reveals acanthosis, mainly limited to the large rete projections The prickle cell layer is growing atypically Little mitosis is present There is a dense lymphocytic infiltration in the dendritic ramifications of the papillary layer

DISCUSSION

DR S J ZAKON About two weeks ago I saw a man with carcinoma of the penis which had been treated for syphilis for some time I reviewed the literature, which is mostly in the field of urology (Melicow, M M, and Ganem, E J Cancerous and Precancerous Lesions of the Penis, *J of Urol* **55** 486, 1946) Early diagnosis is advised because of the serious prognosis It is interesting that there has never been a report of a case of carcinoma of the penis in a Jew, not because of any racial immunity but because of early circumcision In the Mohammedans, who circumcise their children at the age of 13, there is a definite incidence of carcinoma of the penis With early diagnosis some patients will recover In the far advanced case, even with radical amputation and removal of the regional glands, the prognosis is poor

DR THEODORE CORNBLETT In a recent communication of *Science* (**105** 391 [April 11] 1947), Plant and Kahn-Speyer mention that carcinoma of the penis does not occur in persons who have been circumcised in the first few weeks of life and is rare in those who have been circumcised in childhood or in early puberty This induced them to study the carcinogenic action of smegma in mice using material obtained from horses Their work was evidently done carefully with suitable controls and showed that smegma is carcinogenic

This man's lesion was not highly characteristic for carcinoma of the penis, though that diagnosis is probably correct Epitheliomas at this site are usually of the squamous cell type and highly malignant Yet the present lesion began four years ago and the regional lymph glands are not enlarged

DR HAMILTON MONTGOMERY, Rochester, Minn I do not believe that this is an epithelioma histologically There are well defined pearls but few mitotic figures The cells are edematous and large, and there is an area of parakeratosis I think that this is a condyloma acuminatum and not an epithelioma As brought out by the first discusser, epithelioma of the penis usually grows rapidly except those that start on the foreskin In cases in which there is a so-called precancerous stage, moist leukoplakia or erythroplasia, simple circumcision is often enough to prevent the lesion from becoming a frank epithelioma I do not believe that in this patient amputation of the penis will be necessary

DR STURE JOHNSON, Madison, Wis (by invitation) I wonder whether the disease might be histoplasmosis At Ann Arbor, Mich, I saw 2 patients with lesions of histoplasmosis of the genitalia By careful search my co-workers and I were able to demonstrate the organisms in the tissues Schaeffer and his group have also reported cases in which the lesions were present on the genitalia Genital involvement with Histoplasma capsulatum is not unusual The organisms are usually difficult to detect in tissue and to culture I should like to call attention to two articles with photographs of genital histoplasmosis one by Palmer, Almolsch and Shaffer (ARCH DERMAT & SYPH **45** 919 [May] 1942) and the other by Curtis and Cawley (*J Urol* **57** 781 [April] 1947)

DR MAURICE OPPENHEIM (by invitation) The site of this epithelioma is unusual It is not the favorite place The favorite site for carcinoma of the penis is on the inside and on the glans The striking thing is that it has taken four years for it to grow to this size

I do not agree with Dr Montgomery that the histologic observations are atypical with few mitotic figures There is a decided inflammatory reaction surrounding the atypical epithelial growth This carcinoma looks like the so-called mule-spinner cancer, which is produced by lubrication oil used in cotton mills in England and Scotland

follicular lesions on her forehead and similar changes on other areas where one finds Darier's disease I would suggest watching for the development of more evidence of keratosis follicularis

DR F RONCHESE, Providence, R I Dr Bernard Appel suggested to me the diagnosis of ulerythema ophriogenes This would be correct for the miliosis and the erythema, but there is no scarring The keratosis pilaris is limited to a few elements and the miliosis-erythematosis is not limited to the eyebrows but extends to the entire face However, this is an excellent suggestion, and an investigation will be made on the relation of this case to that rare entity which has been called ulerythema ophriogenes sive superciliare Tanzer, folliculitis rubra Wilson, keratosis pilaris rubra faciei Brocq and red keratosis pilaris Bazin This case is a good demonstration of the origin of milia in the hair follicle, the lesions eventually becoming keratosis pilaris, to be differentiated from the pseudomilia following epidermolysis bullosa or pemphigus and the miliary calcified sebaceous cysts It could be considered as a nevoid ectodermal defect

A Case for Diagnosis (Sinuses, Nodules and Ulcers of the Buttock Tuberculosis Colliquativa? Actinomycosis?) Presented by DR JACOB H SWARTZ, Boston

DISCUSSION

DR JACOB H SWARTZ, Boston I have two more tentative diagnoses to add symbiotic infection with Staphylococccus and Streptococcus, and dermatitis factitia plus infection I saw this man only once, and no laboratory work was done I will be glad to report on the case at the next meeting

DR FRANCIS M THURMON, Boston I suggest the diagnosis of dermatitis factitia It is asymmetric, and there was one lesion slightly stained, as though something had been applied, there were tiny white vesicles on the top

DR JOHN G DOWNING, Boston For three years I have been treating a man with a similar eruption, which started on his legs after contact with oil I have seen these eruptions on the arms following the same event Cultures from one patient showed that he had a synergistic combination of hemolytic Streptococcus and Staphylococcus

NOTE—A second biopsy specimen was subsequently removed from the patient's thigh, and a sinus tract found in the depth of the wound was curetted to obtain additional material for mycologic study Histologic observations were nonspecific An extemporaneous preparation from curetted material revealed the "sulfur granules" of actinomycosis, and microscopic study showed the characteristic club-shaped formations Cultural studies were confirmatory

Scurvy Presented by DR GEORGE E MORRIS, Boston

E D, a 45 year old white man, formerly occupied as a welder, complained of an eruption on the feet, legs and thighs of six weeks' duration The first lesion appeared on the left thigh as a red scaly patch Three weeks ago the lower extremities rapidly erupted with dark spots all over the legs The patient has consumed considerable quantities of alcohol, and his diet was distinctly inadequate

At this time numerous fading purpuric blotches may be seen on the lower portions of the patient's legs and the dorsa of his feet The remainder of the lower extremities, the buttocks and lower portion of the trunk show a sparse eruption of small, brownish, scaly patches from 0 5 to 1 5 cm in diameter

Dr Francis M Thurmon, *President*

Dr G Marshall Crawford, *Secretary*

Dec 3, 1947

Necrobiosis Lipoidica Diabeticorum Presented by DR MAURICE M TOLMAN, Boston

Basal Cell Epithelioma, of Nose, Forehead, Left Eyebrow and Left Upper Eyelid Presented by DR JOHN G DOWNING and (by invitation) DR HARVEY B ANSELL, Boston

Tinea of Face (Microsporum Fulvum), Neurodermatitis Circumscripta of Wrist Presented by DR SEYMOUR J WHITE, Lawrence, Mass

Chronic Pemphigus of Eye with Cicatrizing Lesions of Skin Presented by DR BERNARD APPEL, Lynn, Mass

Frambesia Tropica (Yaws) Presented by DR JOHN G DOWNING, Boston

E R, an 8 year old Negro girl, has had lesions on the right heel and left gluteal fold for the past ten months The first lesion to develop was on the right sole, it appeared in December 1946 At that time the child resided in Jamaica, British West Indies, where a diagnosis of yaws was made Treatment consisted of one injection of a bismuth preparation and three of arsphenamine, and the lesion healed Another appeared on the right heel in July 1947, and the patient moved to Boston a month later She was first seen in the Boston City Hospital clinic in September 1947, and by that time another lesion had developed in the left gluteal fold There has been good response to therapy

Examination of the right heel when first seen three months ago revealed a raised, crusted, nontender granuloma, 1 5 by 1 5 cm This was surrounded by a 2 cm area of induration and scaling A similar, but smaller, lesion was present in the left gluteal fold but with less induration At this time there is little to be seen on either area The skin is slightly blacker than this moderately dark negroid integument, and a very indistinct trace of induration can be palpated

A dark field examination of material obtained from the lesions revealed organisms indistinguishable from Treponema pallidum The Hinton and Kahn reactions of the blood were positive on two occasions The hemoglobin content and red cell and white cell counts of the blood were normal, a differential smear revealed 48 per cent polymorphonuclear leukocytes, 42 per cent lymphocytes, 8 per cent monocytes and 2 per cent eosinophils Treatment consisted of intramuscular injections of penicillin, a total of 3,350,000 units was administered

Frambesia Tropica (Yaws) Presented by DR JOHN G DOWNING, Boston

D R, a 5 year old Negro boy, a brother of the preceding patient (E R), has lesions on the left heel and the buccal mucous membrane The first change appeared on this little boy's knee after an injury in April 1947 which failed to heal The ulcer was diagnosed as yaws and treated with three injections of a bismuth preparation plus seven of arsphenamine During the time of treatment several other lesions appeared on both legs, but all were healed by the time therapy was terminated He also came to Boston in August 1947 There was no further trouble

The result of the tourniquet test was positive A hemogram was normal, including a count of the thrombocytes The patient has been given 2 quarts (about 2 liters) of orange and grapefruit juice daily for the past four days

DISCUSSION

DR WALTER F LEVER, Boston I suggest the diagnosis of Majocchi's disease In scurvy one has massive bleeding into the skin Here they are hemorrhagic punctate dots and erythema, as are commonly seen in Majocchi's disease

DR JOSEPH GOODMAN, Boston I agree that the lesions resembled Majocchi's disease, but in my opinion the patient has symptomatic purpura Whether or not he had scurvy could have been ascertained by a vitamin C determination, which was not on the record Since the treatment it would be impossible to say whether he had scurvy Follicular hemorrhages are characteristics of that disease

DR GEORGE E MORRIS, Boston When this man was seen last week he had the follicular hemorrhages which are typical of scurvy One may find large ecchymoses, but it is typically a punctate hemorrhagic disease Last week the result of a tourniquet test was strongly positive The patient was given a diet rich in vitamin C against my orders, and the result of the tourniquet test is now negative The eruption is disappearing That is not typical of Majocchi's disease

Dermatophytosis of the Extremities, Due to Trichophyton Purpureum

Presented by DR SEYMOUR J WHITE, Lawrence, Mass

An intradermal injection of 0 1 cc of Lederle's diagnostic trichophytin extract (1 30) gave rise to an immediate wheal reaction, within ten minutes it measured 1 5 cm in diameter, and numerous pseudopods soon appeared This reaction remained about twelve hours and left a persistent, erythematous, scaly patch, the result of a control injection of isotonic sodium chloride solution was negative Scales removed from the right palm and planted on Sabouraud's medium produced a growth identified as Trichophyton purpureum A biopsy specimen obtained from the left knee exhibited only nonspecific inflammation A number of fungicidal remedies have been applied for prolonged periods of time without response

DISCUSSION

DR JACOB H SWARTZ, Boston I suggest that the mycologic diagnosis be held in abeyance until the culture is more characteristic These lesions do simulate those seen with infection by the organism of Trichophyton rubrum (or T purpureum), but it might be Trichophyton gypseum

DR WALTER F LEVER, Boston Dr Swartz, do I understand that T rubrum or purpureum does not cause sensitization?

DR JACOB H SWARTZ, Boston That is correct, and I would not pay much attention to the immediate reaction A diagnosis should not be made on the cutaneous test alone, and I cannot do so on the strength of the culture as yet

DR FRANCIS P MCCARTHY, Boston Is this organism a possible contaminant or a true pathogen? I should like to know whether it is found on the skin normally

DR JACOB H SWARTZ, Boston I have never seen it as a contaminant

DR JOHN G DOWNING, Boston My co-workers and I cultured 100 specimens of normal skin of patients who had never had a fungous infection Specimens were taken from the scalp, the corners of the mouth, between the toes and the soles Pathogenic fungi were found in 2 cases, neither T purpureum nor Monila albicans (Candida) was isolated

until October 1947, when a lesion appeared on the left heel which was subsequently diagnosed in the Boston City Hospital as yaws Another lesion was discovered on the left buccal mucous membrane at that time

When examined in October, this little boy revealed a superficial ulcer on the left heel It was 1 5 by 1 5 cm , with slightly elevated margins and was not tender Treatment was not started for about a week, and during that time the entire lesion became raised, with the appearance of a chronic granuloma, and was distinctly indurated The lesion on the left buccal mucous membrane consisted of a shallow ulceration measuring 6 by 6 mm , no induration could be detected There were numerous enlarged, nontender posterior cervical and inguinal lymph nodes At present there is nothing on the left heel except a trace of deeper pigmentation The buccal mucous membrane exhibits no change of any kind

Dark field examination revealed organisms indistinguishable from Treponema pallidum The Hinton and Kahn reactions of the blood were repeatedly positive The white cell count of the blood was 13,400, and the red cells numbered 3,640,000 per cubic mm , a differential smear contained 48 per cent polymorphonuclear leukocytes, 50 per cent lymphocytes and 2 per cent monocytes Treatment consisted in administration of 4,000,000 units of penicillin by intramuscular injection

DISCUSSION OF CASES OF FRAMBESIA TROPICA

DR JOHN G DOWNING, Boston At the June Meeting of the American Dermatological Association, Dr Rein reported a series of 1,000 cases of yaws, in all of which the clinical lesions disappeared under treatment, but the serologic reactions became negative in only 15 per cent He gave 1,200,000 Oxford units In the discussion of that report, others who had had experience with yaws stated that the reactions of as high as 40 per cent of their patients remained positive It was clearly indicated that large doses of penicillin are needed to cure this disease, greater quantities will result in better clinical and serologic response

Tuberculosis Luposa Presented by DR. JOSEPH GOODMAN, Boston

Idiopathic Macular Atrophy of Skin Presented by DR WILLIAM R HILL, Boston

Hemangiolymphangioma of Skin Presented by DR S J MESSINA, Boston

A Case for Diagnosis (Mycosis Fungoides or Late Cutaneous Syphilis?) Presented by DR WILLIAM R HILL, Boston

Lupus Erythematosus, Restricted to Lips Presented by DR G MARSHALL CRAWFORD, Brookline, Mass

W G , a 23 year old white American student, presents lesions on his lips of six years' duration This difficulty began as a single fissure in the center of the upper lip which refused to heal It became worse every summer and was aggravated by any exposure to heat At first it would heal in the winter, but it has become worse with the passage of time and now does not heal at any time The fissure spread to become a raw area which slowly extended inward and upward It has been most uncomfortable throughout most of this time, and the greatest discomfort is on the inner aspect of the upper lip Smaller lateral lesions appeared later Two years ago the area measured 2 cm in length (transversely) and was

Leukoplakia of the Penis. Presented by DR JOHN G DOWNING, Boston

J F, a 65 year old white man of Irish birth, a retired elevated railway conductor, is presented with the complaint of soreness and cracking of the prepuce for about two months The patient had applied only petrolatum This afforded no relief, and the condition had become steadily worse

Examination reveals a distinct thinning of the skin of the prepuce and also of the glans penis There is a constricting sclerotic band about 2 cm proximal to the free edge of the prepuce, this has been partially relieved by biopsy, and at that point where the biopsy specimen was taken there is a small crust The remainder of this band is characterized by the appearance of whitish plaques and streaks with several erosions and fissures

The diagnosis from histologic study was reported as leukoplakia There has been no treatment

DISCUSSION

DR FRANCIS P MCCARTHY, Boston Leukoplakia resembles kraurosis in the aged in the sense that there are interstitial changes and leukoplakia and erosion

DR BERNARD APPEL, Lynn The diagnosis of kraurosis of the prepuce was considered The microscopic examination ruled that out, because it did not show typical changes of kraurosis or atrophy

DR FRANCIS P MCCARTHY, Boston The depth of the biopsy specimen may be misleading A deep section is essential and special connective tissue stains are required in order to rule out kraurosis In spite of the histologic changes, I feel that this is kraurosis of the prepuce

DR WALTER F LEVER, Boston I would oppose the diagnosis of kraurosis The histologic picture of kraurosis is characterized by atrophy of the epidermis and degeneration of the collagen In this case there was neither The epidermis was acanthotic, and there was considerable hyperkeratosis The biopsy specimen extended a fair depth into the connective tissue, and it showed no evidence of degeneration There were numerous dilated capillaries and a chronic inflammatory infiltrate There was no evidence of carcinoma The histologic picture is consistent with senile keratosis or leukoplakia

DR FRANCIS P MCCARTHY, Boston In kraurosis there may be areas of atrophy and also leukoplakia with both hyperkeratosis and acanthosis

DR JACOB H SWARTZ, Boston I agree

DR JOHN G DOWNING, Boston There was no evidence of kraurosis or atrophy The skin was infiltrated, fissured and leukoplakic in appearance It probably would go on to cancerous degeneration if neglected This patient can be cured by excising the area affected

Leukoplakia of the Tongue, Buccal Mucosa and Lips, Syphilis Presented by DR F RONCHESE, Providence, R I

A D, a 38 year old white man of American birth, a truck driver, for the past three years had noted white patches on his tongue and lips and on the inside of his mouth The anterior portion of the tongue was raw for much of this time and was somewhat tender, but there was otherwise little discomfort Shortly after the appearance of these lesions the patient was found to have repeatedly positive serologic reactions to tests for syphilis No history referable to the date of infection was obtainable, previous genital or cutaneous lesions were denied No other relevant data were obtained The patient smoked from eight to ten cigars daily

about 5 mm in width The patient was subsequently on naval duty in the tropics, and his lip became so badly swollen that he was incapacitated much of the time He was finally sent back to the United States for that reason The lower lip became involved while he was in the South Pacific, but the condition has never been as severe as on the upper lip

At the present time the external appearance of the lips is grossly normal except for slight edema of the upper lip The inner aspect of the latter reveals intense erythema involving the two center fourths of the lip There is a depression within the affected area as though it had been drawn inward by scarring, but no scarring can be definitely made out A mild degree of maceration is present, and the affected area appears abraded The lower lip is similarly but much more mildly affected and only along the occlusal surface

This is a private patient who was seen in consultation, and there was no opportunity permitted for laboratory study None has been carried out elsewhere Treatment in the past has consisted of liver injections, arsenic drops, several unknown injections, great quantities of vitamins and roentgen ray therapy More recently injections of a gold preparation have been given (quantity unknown), these were stopped because of local reactions at the affected site In the last few months, the patient has received oxophenarsine hydrochloride (mapharsen®), and he feels that this has been responsible for slight improvement

DISCUSSION

Dr Bernard Appel, Lynn, Mass I have only an unhappy prediction to make In my experience in several similar cases the prognosis is bad The disease persists, and nothing I know of has done any of the patients any good

Dr John G Downing, Boston On close examination, the glandular orifices are plainly visible, owing to dilatation of the ducts There is a sticky secretion My diagnosis is cheilitis glandularis apostematosa

Dr William R Hill, Boston In the last two years I have observed 4 patients with dermatitis of the lips somewhat similar to that which this patient presents Three patients related the onset of their eruption to exposure to sun Two were sailors in the Caribbean area, and their disease was diagnosed as lupus erythematosus, they were treated with bismuth and gold preparations without response During the period of observation 1 of these men had a typical eruption of allergic eczema on the back of the hands, and the thought occurred to me that perhaps the disease was a virus infection With this in mind, I treated 2 patients with smallpox vaccine but noted no improvement

Dr G Marshall Crawford, Brookline, Mass This man is not my patient I saw him five or six years ago when his complaint first began and there was nothing present except a small fissure which had healed during the winter months and then recurred He went to war but was discharged from the service because of these lips, receiving treatment from several sources as indicated in the history I recently saw him again in consultation I was not satisfied with the diagnosis as presented, and yet I could not deny it Nevertheless, I think that there is a possibility that he may not have lupus erythematosus Without other lesions, the disease is an enigma

Dr William R Hill, Boston Does the fact that the lips respond to bismuth or gold help in the diagnosis of lupus erythematosus?

Dr Maurice M Tolman, Boston I have searched steadily for a case of lupus erythematosus discoides limited to the mucous membrane I have heard of such cases but have yet to see one I am inclined to think this is not lupus ery the-

The distal half of the dorsal aspect of this man's tongue is almost completely denuded of epithelium Within this area there are numerous small, white, infiltrated islands and some atrophic scarring The entire distal half of the tongue appears somewhat shrunken and atrophic, the margins are slightly elevated and are marked with alternate red and pearly gray striations The patient's lips and buccal mucosa also exhibit scattered small plaques of white atrophic tissue

Treatment has been carried on by the patient's family physician It consisted of fifty-five injections of bismuth salicylate and thirteen of oxophenarsine hydrochloride (mapharsen®) between May 1943 and October 1945 The dosage of these treatments was not known, there had been no clinical improvement The patient was smoking less during that time In March 1947 3,000,000 units of penicillin in oil and wax were administered, without detectable effect on the oral changes

The Hinton and Kahn reactions of the blood had both remained consistently positive up to the time of presentation Histologic examination of a biopsy specimen taken from the tongue revealed the following changes consistent with leukoplakia, acute ulceration and inflammation of the mucosa, with no evidence of malignancy

DISCUSSION

DR FRANCIS P MCCARTHY, Boston The erosion on this patient's tongue came on suddenly, and the ulceration has continued for three years As a result of inadequate treatment for syphilis there developed a smooth atrophy suggestive of glossitis luetica atrophica The failure of the ulceration to heal may be explained by interstitial connective tissue changes associated with limited blood supply from an old endarteritis I have recently studied syphilitic glossitis in postmortem specimens wherein interstitial sclerosis associated with decided narrowing of the lumen of arteries and atrophy of the overlying papillae are constantly found The granulation tissue as seen in this case does not become malignant, but the leukoplakic lesions in the periphery of the lesion may show a malignant tendency

DR JOHN G DOWNING, Boston When I first saw this man's tongue I was impressed by the sharp outline of the granulations and the intervening islands of leukoplakia I ordered two biopsies to eliminate malignancy, the diagnosis from both specimens was chronic inflammation I might suggest a diagnosis of stomatitis factitia I have seen 3 cases in which this condition was proved to be self-inflicted This man has syphilis, and I believe that he has been applying some strong chemical to his tongue to remove the previous leukoplakia

DR FRANCIS M THURMON, Boston Around the denuded areas there is definite leukoplakia of the tongue I think that the prognosis is serious, because once cancer of the tongue develops in a patient with tertiary syphilis there is no treatment that is successful

DR FRANCIS P MCCARTHY, Boston I am interested in what Dr Downing said because it seems unusual to see granulation continue so long without healing The blood supply is greatly diminished, and that may be a factor Why anyone should inflict a lesion of this kind on his own tongue is difficult to understand without some compelling motive such as the collection of compensation The patient told me that it developed overnight

DR F RONCHESE, Providence, R I If the changes on this man's tongue are regarded as potentially malignant, the entire surface should be removed with the coagulating loupe

DR JOHN G DOWNING, Boston Syphilis is in the background of this disease of the tongue, aggravated by a therapeutic attempt to cure it

matosus This man has a protruding lower lip I have seen a number of men within the ages of 18 to 25 with carcinomatous degeneration of the lower lip following extensive exposure to sun I have also seen lupus erythematosus of the lip which soon developed into carcinoma, and I think this patient will have carcinoma Lupus erythematosus of the mucous membrane does not respond well to bismuth

DR BERNARD APPEL, Lynn, Mass Several years ago I saw a middle-aged woman with lesions on the inner aspect of the lower lip that looked like either lichen planus or the climacteric type of leukoplakia The eruption turned into a more classic lichen planus and subsequently spread onto the buccal mucosa A biopsy was done and the microscopic examination showed either lupus erytnematosus or chronic inflammatory reaction of mucous membrane It was not until two or three years later that the lesions finally extended onto and beyond the vermilion borders of both lips, showing the classic cutaneous changes Although, strictly speaking, that disease was not limited to the mucous membrane, nevertheless it started there and was localized there for a long time Going back to the present case, I feel that this is more likely to be lupus erythematosus of the mucosa and less likely to be carcinoma of the lip

Pityriasis Rubra Pilaris Presented by DR LEON BABALIAN, Portland, Maine

Lichen Nitidus Presented by DR E A LAFRENIERE, Arlington, Mass

Lichen Planus Presented by DR GEORGE MORRIS, Boston

Case for Diagnosis (Nevus Linearis? Linear Lichen Planus?) Presented by DR GEORGE MORRIS, Boston

Multiple Idiopathic Hemorrhagic Sarcoma of Skin Presented by DR G MARSHALL CRAWFORD, Brookline, Mass

Pseudoxanthoma Elasticum of the Neck with Angioid Streaks Presented by DR JOHN ADAMS JR, Boston

This case provides a classic picture of pseudoxanthoma elasticum, first described by Balzer in 1884 It may be located on the flexor folds, the axillas, the upper and inner surfaces of the thighs and the abdomen, and in very rare cases the mucous membranes are also affected The lesions are asymptomatic but may persist for years Areas of calcification have been reported in the affected parts The angioid streaks of the retina, as noted in this patient, occur in about 25 per cent of the cases They are probably a part of a generally defective elastic tissue Hypertension may be found in some of the patients and also degeneration of the elastica of the larger arteries This might account for the hemorrhages which occur in various organs, including the brain The cause is unknown, and the disease is harmless

Leukemia Cutis (Type Unspecified) Presented (by invitation) by DR PAUL J CATINELLA, Boston

Lymphatic Leukemia with Herpes Zoster, Generalized Presented by DR S J MESSINA, Boston

DR FRANCIS P MCCARTHY, Boston That is a reasonable explanation, and the factitial element in this case may explain the unusual findings

Psoriasis, Keloids Following "Injections" Presented by DR LEO KORETSKY, Chelsea, Mass

A Case for Diagnosis (Erythema Multiforme Exudativum? Bullous Impetigo?) Presented by DR GEORGE SCHWARTZ, Malden, Mass

DISCUSSION

DR MILDRED L RYAN, Brockton, Mass I think that this 3 year old child has dermatitis medicamentosa She has had frequent attacks of asthma Has she been given any iodides or bromides?

DR GEORGE SCHWARTZ, Malden, Mass I saw this girl ten days ago At that time she presented bullae of ½ to ¾ inches (1 to 2 cm) in diameter, arising from normal skin They were on the arms, legs, abdomen and neck, there also were six or eight vesicles on the scalp I found nits and thought that she had bullous impetigo I have not seen her since then, and today she shows a different picture, one would think that she was another patient

DR S J MESSINA, Boston I think that this is a case of Loeffler's syndrome She had a high eosinophilic count and a history of asthma, which are characteristic of that disease There may or may not be an eruption which can suggest erythema multiforme I think that Loeffler's syndrome is a strong possibility in this case

DR JOHN G DOWNING, Boston I agree with the diagnosis of Loeffler's syndrome Recently I saw a patient with a history of asthmatic attacks, mottling on the chest and an eruption resembling erythema perstans on the chest, the blood picture showed a high eosinophil count

Dr Francis M Thurmon, *President*

Dr G Marshall Crawford, *Secretary*

New Haven, Conn, Oct 8, 1947

A Case for Diagnosis (Xanthomatosis?) Presented by DR MAURICE J STRAUSS, New Haven, Conn

E C, a 2 year old white girl, acquired a solitary lesion on the right cheek at about the age of 4 months This slowly increased in size, and gradually a few similar lesions developed around the original one The latter attained a size of 9 by 6 mm before excision six months ago They have been asymptomatic

On the right cheek there is a group of six small, solid, slightly elevated brownish red nodules each about 4 or 5 mm in diameter

Histologic examination revealed only a chronic inflammatory reaction

DISCUSSION

DR LEON BABALIAN, Portland, Me Although there is no regional enlargement of lymph nodes in this case, it is difficult to rule out lupus vulgaris

DR ALFRED HOLLANDER, Springfield, Mass My opinion is that these lesions belong to the group of localized xanthoma I did not study the slide too well, but the section did show some foam cells

Chronic Pyoderma (Staphylococcus Aureus) Presented by DR GEORGE MORRIS, Boston

A Case for Diagnosis (Sarcoid? Tuberculid?) Presented by DR BERNARD APPEL, Lynn, Mass

Hodgkin's Disease of the Skin Presented (by invitation) by DR PAUL J CATINELLA, Boston

D F, a 34 year old white housewife of Irish birth, presents a lesion on the front of the left thigh which is said to be of only nine weeks' duration It appeared first to be a small blister and then became a shallow ulcer which gradually enlarged The lesion had been asymptomatic

At the time of first examination, several weeks ago, a solitary lesion was found on the anteromedial aspect of the patient's left thigh about 4 inches distal to the inguinal ligament This proved to be a moderately shallow circular ulcer of 2 5 cm diameter The center portion of the base of the ulcer was slightly raised, granulomatous and moist on the surface The borders were firm, and the tissue about the periphery was deeply infiltrated

A biopsy specimen was obtained, and the histopathologic examination revealed changes indicating a diagnosis of Hodgkin's sarcoma The white cell count of the blood was 2,750 per cubic millimeter, a differential smear revealed 56 per cent polymorphonuclear leukocytes, 38 per cent lymphocytes, 3 per cent monocytes and 3 per cent eosinophils Roentgenologic examination of the chest, lumbosacral portion of the spine, pelvis and hips revealed nothing abnormal except a "condensing osteitis of the right ilium"

The patient's lesion was widely excised two weeks ago The scar is soft, without suggestion of recurrence

DISCUSSION

DR FRANCIS M THURMON, Boston What is the prognosis in this case?

DR JOHN G DOWNING, Boston We should raise the question of further therapy at this point Have sufficient measures been taken?

DR BERNARD APPEL, Lynn, Mass When I first saw the patient, I considered this to be syphilis, probably an unusual extragenital chancre A week or so later this was an oozing, exuberant, red, moist, granulating, mushroom type of lesion with the edges firm and curled outward, and then it looked like either a rapidly growing carcinoma or sporotrichosis, or perhaps one of the other mycotic granulomas The last thing in my mind was Hodgkin's disease, and when I heard the microscopic diagnosis I could hardly believe it, yet the slide shows cells of the immature lymphoblastoma type that are consistent with Hodgkin's disease

DR MAURICE J STRAUSS, New Haven, Conn As the patient was presented today, there was no lesion to be seen However, having now looked at the colored photograph, I feel that we would be justified in making a diagnosis of mycosis fungoides of the tumor d'emblee type It is not always easy to tell mycosis fungoides from Hodgkin's disease microscopically, and it is quite possible that this error could occur I recall a similar case presented to this Society several years ago at a meeting at New Haven, Conn The man died six years later, I believe in an accident, and had never had any known recurrences The lesion was in the lumbar region, and a simple but wide excision was performed with skin grafting

DR E MYLES STANDISH, Hartford, Conn I recall that about fifteen years ago I saw an almost exact counterpart of this lesion as far as color and induration are concerned, it proved to be lupus vulgaris

DR JOSEPH MULLER, Worcester, Mass I also thought of tuberculosis, but with pressure under a glass slide there was absolutely no sign of the typical apple jelly color that lupus vulgaris should show

DR ELLWOOD C WEISE, Bridgeport, Conn Although the light was poor where this little girl was shown, I thought that I could see a number of comedos in the affected area I have seen cases of precocious acne accompanied with chronic granulomatous lesions which were similar in appearance

DR BERNARD APPEL, Lynn, Mass I had the same first impression, but then I moved the baby into better light and saw that these pinpoint black dots were not comedos but little deposits of pigment My next feeling was that this was a nevus xanthomatosus I did not see the slide, but I do not consider the presence of foam cells essential

DR G MARSHALL CRAWFORD, Brookline, Mass There were definite small pigmentary deposits The possibility of a sebaceous nevus came to mind in view of the yellowish red color and firm consistency of the nodules I searched the section for foam cells but saw only a number of large pale reticulated structures which suggested portions of sebaceous glands cut at the edges

DR JACOB H SWARTZ, Boston This lesion may be given several different names It does not matter whether it is called nevus comedonicus or a sebaceous nevus, it falls into the same group I do not believe that a foam cell will ever be found

Granuloma Annulare Presented by DR MAURICE J STRAUSS, New Haven, Conn

Keratosis Follicularis Presented by DR ALBERT LEVENSON, Bridgeport, Conn

Dermatitis Herpetiformis Presented by DR CHARLES N SULLIVAN, New Britain, Conn

E S, a 42 year old white printer, first had severely pruritic lesions on the back of the left thigh four years ago, the eruption slowly spread and became generalized There have been several remissions and exacerbations, but the eruption has never completely cleared

There are groups of crusted papules, each lesion about 2 to 3 mm in diameter, scattered profusely over the trunk and extremities On the cheeks there are vesicles, some recently abraded and crusted There are many macular scars with pigmentation

Examination of the blood revealed nothing abnormal except 11 per cent eosinophils Microscopic examination of a biopsy specimen, reported by Dr Wilbert Sachs, of New York, showed the vessels of the middle and upper parts of the cutis dilated and the walls slightly thickened There was a perivascular infiltrate of small round cells and wandering connective tissue cells There was moderate interstitial edema in the upper part of the cutis The epidermis was regularly acanthotic, with an impetiginized cavity which had partially broken through at one point

Sulfapyridine relieved the pruritus but produced urticaria Sulfadiazine and roentgen ray treatment produced a remission, but the eruption recurred when this

For all practical purposes, that is what has been done upon the patient presented today, and it may well be all the treatment that will be necessary

DR WALTER F LEVER, Boston The histologic section was densely infiltrated with anaplastic and immature reticulum cells Some of them had large nuclei, and others were multinucleated It is perhaps best to call this lesion a reticulum cell lymphoma Concerning the prognosis, I agree with Dr Strauss It is not uncommon for reticulum cell lymphoma to start as a single lesion on the skin or elsewhere, and if this lesion is excised completely there may be no recurrence

DR LEON BABALIAN, Portland, Maine Dr MacKee advised wide excision followed by irradiation

DR WALTER F LEVER, Boston I do not believe that irradiation is generally done Most lesions are in lymph nodes, where irradiation is impractical Radical excision is best, irradiation is optional

DR BERNARD APPEL, Lynn, Mass The matter of terminology of this group of tumors is still undecided When the proponents of the various terms get together and agree on what to call these cells, they may find that they are all talking about the same thing I think that if Dr Catinella were to go to the pathology department of the hospital with which I am associated and look up the original biopsy slides, he would find that they correspond closely to the section exhibited today Many of us have seen a solitary lymphoblastoma cured by surgical excision This will probably turn out to be that type of case

DR PAUL J CATINELLA, Boston (by invitation) I am sorry that the members did not have the benefit of all of the slides Sections of specimens taken a week later showed a picture resembling reticulum cell sarcoma except for one feature which established the diagnosis of Hodgkin's sarcoma That was the presence of multinucleated and polymorphonuclear giant cells of the Dorothy Reed type Wide excision was advised in the hope that if the lesion had started in the skin, eradication of the primary focus might be followed by a cure It was a long chance If the condition were not treated, the prognosis for life would vary from one to three years

DR JOHN G DOWNING, Boston The most complete monograph on lymphomas is that of Jackson and Parker (Jackson, H, Jr, and Parker, F, Jr Hodgkin's Disease and Allied Disorders, New York, Oxford University Press, 1947) It covers about every phase of this group of diseases, is clearcut and presents a clever classification according to life expectancy The reason I inquired about treatment is that we consulted Jackson, and he suggested excision, adding that the quicker excised, the more chance this patient had of living

Sarcoidosis of the Skin Presented by DR WALTER F LEVER, Boston

treatment was discontinued Tripelennamine hydrochloride (pyribenzamine hydrochloride®), 50 mg four times a day, is of slight value at this time

DISCUSSION

DR BERNARD APPEL, Lynn, Mass I think that the case is clinically typical of dermatitis herpetiformis and accept the diagnosis as presented The patient said urticarial reactions were so severe that he was completely covered with wheals Since sulfapyridine produces such a reaction, I suggest that tripelennamine hydrochloride be used in appropriate doses, I should prescribe 600 or 800 mg daily A patient with dermatitis herpetiformis who took sulfapyridine with fairly good results was recently given diphenhydramine hydrochloride (benadryl hydrochloride®) for a comparison She noted more lasting relief and recession of the lesions than with sulfapyridine One expects some trouble from sulfonamide drugs, and it is much safer to use tripelennamine or diphenhydramine in large doses

DR MAURICE M TOLMAN, Boston Since 1938 I have had under personal observation 3 patients with dermatitis herpetiformis who have taken sulfapyridine continually without reaction, and it controlled their disease I am a little afraid of continuing its use indefinitely We decided to try diphenhydramine and tripelennamine in doses of 600 mg daily in carefully controlled patients in the hospital but observed no relief from pruritus or diminution of the lesions We then administered sulfapyridine, there was immediate response, and remission took place

DR JOSEPH GOODMAN, Boston On the other side of the picture, I should like to mention a patient who took sufficient sulfapyridine to produce a blood level of 7 mg per hundred cubic centimeters with but little effect on the dermatitis herpetiformis That patient has responded better to 400 mg of diphenhydramine daily than to the large doses of sulfapyridine One must thus conclude that some patients do better with one drug and some with the other I cannot maintain that sulfapyridine controls the disease in all patients with dermatitis herpetiformis, the same is true of tripelennamine and diphenhydramine

DR NEVILLE KIRSCH, Hartford, Conn Some physicians in general practice have treated dermatitis herpetiformis with nicotinic acid

Hemangiolymphangioma of Tongue Presented by DR MAURICE J STRAUSS, New Haven, Conn

Sarcoidosis of Skin Presented by DR E MYLES STANDISH, Hartford, Conn

Adenoma Sebaceum Presented by DR MAURICE J STRAUSS and (by invitation) DR LOUIS O'BRASKY, New Haven, Conn

H M is a 12 year old white school girl About two months after she was born, her parents first noticed thickening under the toe nails and finger nails At the age of 7 years, papules appeared on the face Both parents are living and well and have no lesions of the skin although both are mentally defective One brother has a speech defect and is classified as mentally defective but shows no cutaneous abnormality Two brothers and two sisters are mentally and physically normal The patient herself is mentally normal

On the face there are numerous groups of small discrete white papules, symmetrically distributed over the forehead, on the sides of the nose and on the zygoma All the nails of the hands and feet are thin, soft and discolored, especially the nails of the great toes, and their growth is retarded There are brown fibrotic

Jan 7, 1947

Erythema Induratum Without Ulceration Presented by Dr Maurice J Costello

P M , a Puerto Rican woman aged 27, is presented from the Dermatologic Clinic of Bellevue Hospital with an eruption involving the thighs and the lower third of each leg of about one year's duration The patient had pulmonary tuberculosis ten years ago, but she states that a recent roentgenogram of her chest showed arrested pulmonary disease, and examinations of the sputum did not reveal tubercle bacilli Her menses are normal A brother and sister died of tuberculosis

The patient states that her eruption began as small red papules which were painful and frequently broke down and drained pus (This was not verified in the four months the patient has been under observation in this clinic) The lesions become painful when she arises each morning and also on exposure to cold

The eruption is present on the lower thirds of the legs and about the ankles and consists of scattered, erythematous, scaly, nodular and plaque-like lesions, some of which are fluctuant but do not drain pus Others are indurated

A section of the skin showed mild acanthosis of the epithelium, with some downgrowth of the rete pegs into the corium In the superficial and deep corium numerous granulomatous lesions were seen These consisted of indistinct epithelioid cells with occasional multinucleated giant cells in the central portions There was some proliferation of fibrous tissues and young blood vessels about these nodules A moderate infiltration of lymphocytes and large mononuclear cells and a few polymorphonuclear and plasma cells were present throughout the corium but primarily in the granulomatous lesions In and about the lesions there were varying numbers of mononuclear cells filled with brown granular pigment Deep in the corium some normal adipose and glandular tissue was seen Elastic tissue staining revealed the absence of elastic fibers through the upper corium wherein the tubercles were seen The histologic diagnosis was erythema induratum

The patient underwent thoracoplasty about ten years previously A roentgenogram of the chest three days ago showed no activity

DISCUSSION

Dr S Irgang It is not possible to make a definite diagnosis of erythema induratum in this case because the subcutis was not included in the section That is the layer in which the typical changes of this disease are found

Dr Fred Wise The diagnosis of erythema induratum is made in this case by clinical observation alone I should say that this is the typical textbook picture of erythema induratum of the Bazin type The characteristic histologic changes occur in the deeper veins especially, but a clinical diagnosis is acceptable in this instance A histologic diagnosis can be made, even in the absence of tubercle formation

tumors under most of the nails, elevating the plate from the bed The extensor surfaces of the arms and legs, the back and the buttocks are dry with follicular hyperkeratosis

Examinations of the blood and urine showed normal conditions The Kahn reaction of the blood was negative

DISCUSSION

DR ALBERT LEVENSON, Bridgeport, Conn I should call this a case of milium Clinically the lesions do not resemble those of Pringle's adenoma sebaceum

DR ALFRED HOLLANDER, Springfield, Mass I definitely exclude Pringle's disease I feel especially that the numerous lesions on the forehead are those so often seen in the common type of acne and that if one tried to remove them, one would find some to be comedos, some to be milium-like and some to be hygromas Further inspection of the face revealed other small comedo-like lesions The lesions on the face fall partly into the acne group and partly into the hygroma group Those on the forearms should be classified as keratosis pilaris

DR G MARSHALL CRAWFORD, Brookline, Mass I agree with what has been said, but I insist on the diagnosis of tuberous sclerosis, also making a plea that all such cases be called tuberous sclerosis Adenoma sebaceum and other subsidiary diagnoses may be added as presented by each individual patient The cutaneous and visceral anomalies reported in cases of tuberous sclerosis are almost beyond enumeration A wide variety of cutaneous changes occur Most characteristic are the subungual keratoses which in this girl involve every one of her twenty nail beds She does not show the characteristic adenoma sebaceum, as every one else has said The milium-like changes do not exclude the diagnosis of tuberous sclerosis, neither do the keratosis-pilaris-like changes, which in this case are not limited to the usual areas but are diffuse The entire skin shows varying degrees of follicular hyperkeratosis There is also a background of mental deficiency and other abnormalities, which is entirely characteristic of tuberous sclerosis

DR EARL GLICKLICH, Boston I have observed a case of adenoma sebaceum in which it was necessary to have fundus examinations for additional information to make a diagnosis Such an examination usually shows a strawberry or mulberry type of growth on the fundi I suggest that an ophthalmologist examine this patient's eyegrounds

DR G MARSHALL CRAWFORD, Brookline, Mass There should also be roentgen examinations of the chest and kidneys, since polycystic kidneys and various other visceral changes are much commoner than is usually supposed

Erythroplasia of Queyrat, Penile Presented by DR MAURICE J STRAUSS, New Haven, Conn

Dermatitis Exfoliativa Presented by DR MICHAEL J MORRISSEY and DR HARRY S REYNOLDS, Hartford, Conn

Squamous Cell Carcinoma of Leg, Blastomycosis? Presented by DR ELLWOOD C WEISE, Bridgeport, Conn

Multiple Idiopathic Hemorrhagic Sarcoma of Skin Presented by DR MAURICE J STRAUSS, New Haven, Conn

DR S IRGANG In the absence of ulceration, it is not possible to differentiate erythema induratum clinically from nodular nonsuppurative panniculitis In view of the equal distribution of lesions about the legs and also because of the absence of a single ulcerated lesion during a period of fourteen months, I favor a clinical diagnosis of nodular nonsuppurative panniculitis

DR CHARLES WOLF To make a diagnosis of erythema induratum without real corroboration is rather risky I had the experience recently with a patient who had a solitary lesion on the calf of the leg for six months, with a history of pulmonary tuberculosis and thoracoplasty I took it for granted that the lesion was erythema induratum I was to perform a biopsy, but after one visit the lesion healed so much that I thought biopsy unnecessary The surgeon thought the patient should go back into the hospital for further operative treatment because of infection in the pleura I told him the cutaneous lesion was a manifestation of tuberculosis, and he removed it while operating on the chest Biopsy revealed chronic inflammatory tissue The patient presented tonight may have undergone a thoracoplasty, but the lesion on the leg may be an entirely different entity Therefore, we must have further evidence before we can accept it as Bazin's disease

DR FRANK C COMBES There is a remote possibility that this is not erythema induratum, but from a clinical standpoint I cannot favor any other diagnosis I will admit that this disease has its inception in the subcutis, but, as I understand it, the histologic section conformed to the changes seen in erythema induratum Because of its typical clinical features, I would agree with the diagnosis as presented, even if the histologic picture did not support it

DR TIMOTHY J RIORDAN I believe that is an adequate description, and the condition can be interpreted as Bazin's disease After all, the pathologic changes can be tuberculoid or tuberculous One does depend on the deep site of the biopsy material, and all that is necessary is to find changes in the region of the deep cutis, the region of the deep plexus of blood vessels It is true that it is best to include adipose tissue However, if by chance enough of the deep corium is got to correspond with the description given tonight, I would certainly accept it as erythema induratum, or Bazin's disease In my experience with erythema induratum tubercle formation or an entirely tuberculoid type of reaction may be present Often the diagnosis can be made without the appearance of classic tubercles as we know them, with caseation necrosis or pure epithelioid structure Inflammatory changes plus involvement of the blood vessels, tuberculoid reaction plus blood vessel reaction, or tuberculous reaction plus blood vessel reaction can establish the diagnosis

DR ISADORE ROSEN I agree with those who believe, on clinical grounds, that this patient is suffering from Bazin's disease When lesions of this disease break down, they frequently resemble gummas, and even on microscopic examination it is difficult to distinguish them from lesions of syphilis

DR MAURICE J COSTELLO I do not know how far Dr Irgang expected us to go in taking a biopsy, but, as Dr Rosen just indicated, I have seen lesions of papulonecrotic tuberculid accompanied with lesions of typical erythema induratum in the same patient

Blastomycosis of the Skin Presented by DR MAURICE J STRAUSS and (by invitation) DR HARRY SIGEL, New Haven, Conn

H M, a 23 year old white electrician, first noticed a "pimple" on his left shoulder about a year ago For six months immediately preceding the development of this lesion he lived in Connecticut From September 1945 to February 1946 he was in Korea and from March to September 1945 in Okinawa Prior to that he lived in Idaho While in Okinawa, some "sores" developed on the back of his neck and on the extensor surfaces of both hands These healed spontaneously within about six weeks The lesion which marked the onset of the present condition grew slowly and progressively As the border extended, the central portion partly healed

There is now a large lesion on the left shoulder, about 18 cm long and 10 cm wide The border is circinate, bluish red, raised, rolled and indurated The marginal elevation slopes gradually toward the center of the lesion The border is most prominent at its medial edge, and there it appears somewhat verrucous Several portions of the margin are tender and exude small drops of pus on pressure The lateral edge of this lesion is flatter and more cicatricial

Direct microscopic examination of exudate from the lesion showed round, thick-walled, budding cells Cultural studies yielded a typical growth of Blastomyces dermatitidis hyphal with chlamydospores at room temperature and budding cells when incubated There has been no treatment administered

DISCUSSION

DR JACOB H SWARTZ, Boston I saw the slides and culture mounts and agree with the diagnosis of blastomycosis The culture was difficult to identify, as are all cultures in such cases The one grown at room temperature showed the hyphal type of growth with chlamydospores The one grown on Sabouraud's medium at incubator temperature exhibited the typical budding cells which are characteristic of Blastomyces Clinically the lesion was also compatible, with wartlike projections from the border The question at present is how to cure it I suggest a combination of sulfonamide drugs and roentgen rays Beyond that, I suggest ethyl iodide by inhalation Excision would be satisfactory if the condition is not systemic It is advisable to have a roengen examination of the chest and other structures that are liable to be involved, together with a complete neurologic examination and study of the spinal fluid The scar from a previous vaccination also shows early lesions of blastomycosis

DR ADRIAN SCOLTEN, Portland, Maine *Must one go out of the country to* acquire this disease?

A Case for Diagnosis (Erythroderma Ichthysiforme?) Presented by DR FREDERICK REISS

E G, an unmarried Puerto Rican woman aged 39, was admitted to the dermatologic service of Bellevue Hospital in October 1945 because of a generalized exfoliating erythroderma, which, however, did not include the mucous membranes The past history and the family history were not contributory There was no history of allergy, of ingestion of drugs or of any previous antisyphilitic therapy According to the patient, the eruption started on the face and neck about eight months previously and gradually spread over the entire body At the onset, blisters were present She had always lived in Puerto Rico until the fall of 1945

The patient has remained hospitalized up to the present During this period the clinical picture has been essentially unchanged except for the progressive development of generalized erythroderma and keratoderma, particularly of the palms and soles, and pronounced alopecia of the scalp During the first year of hospitalization there was a weight loss of 40 to 50 pounds (18 to 22 7 Kg), but during the past six months the weight has remained constant at approximately 80 pounds (36 3 Kg) The appetite has been good during the entire course There have been occasional febrile episodes, with the temperature rising to 102 to 103 F for twenty-four to forty-eight hours at a time

At present the skin over the entire body is erythematous and scaly The palms and soles present a decided keratoderma The nails are dystrophic, thickened and extremely brittle In addition, there are slight generalized lymphadenopathy and almost total alopecia

Reaction of the blood to the serologic test for syphilis was negative Repeated urinalyses showed a normal reaction A complete blood count revealed a hemoglobin content of 9 5 Gm, erythrocytes 3,520,000 and leukocytes 8,700, with 53 per cent polymorphonuclear leukocytes, 41 per cent lymphocytes and 6 per cent eosinophils Routine chemical examinations of the blood all gave essentially normal findings The basal metabolic rate was +36 per cent The reaction to the congo red test for the presence of amyloid was negative

Biopsy showed a nonspecific picture of acanthosis and hyperkeratosis

Additional laboratory investigations gave the following results The blood sugar was 92 mg per hundred cubic centimeters and the nonprotein nitrogen 27 mg The albumin-globulin ratio was 3 2 to 2 6 Gm per hundred cubic centimeters The blood chloride level (expressed as sodium chloride) was 456 mg per hundred cubic centimeters The serum cholesterol level was within normal limits The blood calcium was 10 4 mg per hundred cubic centimeters, and the serum potassium level was 16 2 mg The twenty-four hour urinary output of ketosteroids was 7 mg (normal, 10 to 15 mg)

DISCUSSION

DR FRED WISE It is possible that Dr Reiss' diagnosis is the correct one, but I believe the diagnosis of pemphigus vegetans should be entertained

DR FRANK C COMBES I have observed this patient for the better part of a year, as have other members of our staff I can well understand how, on looking at her for only a short time, Dr Wise might consider pemphigus However, this patient has never had any bullae, and at no time have we entertained this diagnosis I have never observed a dermatosis of exactly this nature Her palms are remarkable Here there is some erythema, but the most prominent feature is the hyperkeratosis, which is not that usually observed on the palms and soles It actually accentuates the normal cutaneous markings No topical therapy has succeeded in

DR JACOB H SWARTZ, Boston No It is named North American blastomycosis only to differentiate it from European blastomycosis

DR MAURICE J STRAUSS, New Haven, Conn *Is there any particular sulfonamide preparation which should be chosen?*

DR JACOB H SWARTZ, Boston I have had little experience in the use of sulfonamide drugs in treatment of blastomycosis, but several drugs of that group have been successfully used Iodides should not be used until after an intradermal test with blastomycin has been made It may be necessary to desensitize the patient before administering iodine compounds The same applies to patients with moniliasis

DR ALBERT LEVENSON, Bridgeport, Conn I should like to ask Dr Swartz whether the danger in giving sodium iodide is due to the fact that the patient has blastomycosis Sodium iodide is used in many conditions

DR JACOB H SWARTZ, Boston I believe that the form of iodide does not matter It is the allergic factor that counts The principle is the same as that in giving iodides to a patient with tuberculosis The reaction is on an allergic basis and may be compared to a Herxheimer reaction Any patient with a systemic fungus infection may be a poor risk

DR HARRY SIGEL, New Haven, Conn (by invitation) I saw several patients with blastomycosis of the skin in a military hospital, and all of them were treated with iodide without previous desensitization Though they were not previously tested for allergy to blastomycosis, none of those patients had ill effects

Bowen's Disease Presented by DR WILLIAM B SWARTS, Greenwich, Conn

eradicating this keratosis The odor which has been mentioned is that observed from other patients with hyperkeratosis and vegetative dermatosis and is due to putrefaction in the sulci and crevices

DR ISADORE ROSEN As far as erythroderma ichthysiforme is concerned, the clinical features do not fit in with that disease, which is almost invariably of congenital origin I am unable to make an absolute diagnosis, but I would suggest the possibility of Darier's disease

DR PAUL GROSS It would be interesting to hear about the therapy which this patient received during her year of hospitalization

DR FRANK C COMBS At one time we entertained the same idea as the chairman—that the patient might have Darier's disease, but this was ruled out on histologic grounds The patient has received large doses of vitamin A more or less empirically More recently, we have treated her according to the suggestion of Dr Goldzieher that this dermatosis was a manifestation of some endocrine disturbance occurring during the menopause I am sorry Dr Goldzieher is not here tonight, but Dr Reiss will be able to explain the therapy administered during the last two months, which I think is more logical than the previous treatment

DR PAUL GROSS There were two features which seemed important in this case One was the tongue, which had a magenta color and was rather smooth in appearance Secondly, there was pronounced anemia, which apparently has not changed to any degree during a year of therapy In other words, we are dealing with a case of generalized exfoliative erythroderma associated with lesions of the mucous membrane and profound anemia Such cases may respond to intensive therapy with vitamin B complex and particularly folic acid The fact that the patient is a Puerto Rican further suggests dietary deficiency, since we know that many of these people avoid meat in their diet If nutritional therapy is ineffective, the diagnosis of pemphigus foliaceus could be entertained This disease seems to be more common in South American countries than in the United States

DR FREDERICK REISS I have seen the patient only during the last two months I do not believe that I can offer a definite diagnosis, but since the onset of the disease was associated with bullae, Dr Wise's suggestion of pemphigus is a possibility I was led to think, however, that the disease process could be ichthysiform erythroderma, since the wet type starts with blisters We also have to recognize the other form, the dry type without blisters This case definitely began with blister formation, which later turned into erythroderma with plantar and palmar hyperkeratosis Hyperhidrosis is emphasized by Brocq and subsequent observers as occurring in erythroderma ichthysiforme, with, at times, loss of hair and sometimes increased growth of hair and nail plates I would not say that this case fits into the description altogether, because, as the chairman emphasized, in most instances the condition is hereditary Apart from that, there are many features suggestive of erythroderma ichthysiforme, and one may consider this a tardive form

An interesting symptom which I believe led us to the present therapy with estrogens was the amenorrhea which began six years ago, which may have some relationship with the disturbed keratinization I think the majority of French observers have emphasized endocrine deficiency, either ovarian, thyroid or adrenal This patient shows a definite endocrinopathy, not only clinically but biochemically, since there is tremendously decreased excretion of 17-ketosteroids The normal should be 11 to 15 mg, whereas she excretes only 7 mg All in all, I think that there is definite indication of an endocrine deficiency, but I cannot offer a definite diagnosis

Against the diagnosis of condyloma acuminatum are the hard consistency, the broad base and the smooth surface The unusual factor is that these cancers are of long duration without metastases to lymph nodes

Epidermodysplasia Verruciformis Presented by DR MARCUS R CARO and (by invitation) DR LAURENCE L PALITZ

B G, a white girl aged 16, first had cutaneous lesions on the wrists and ankles at the age of 10, with gradual extension to the present distribution There was some improvement each summer, but the lesions never disappeared, there were no subjective symptoms There was no history of parental consanguinity

On the dorsal surface of the hands are patches of erythematous, raised papules with verrucous surfaces On the left hand these papules extend across the outer side of the thumb to involve the volar surface of the thumb for a short distance On both hands they extend around the ulnar side of the wrists to the flexor surface and then along the ulnar part of the flexor surface of the forearms to the cubital fossae There is a diffuse patch of erythematous and slightly hyperkeratotic dermatitis about the right axilla and also on the inner surface of the right arm There are also diffuse lichenified patches on the outer surface of the hips, more on the right side, and on the outer surface of the right knee, while on the front of the left knee are many small warty papules On both insteps are many pea-sized, warty papules, which extend upward to the dorsal surface of the feet, across both ankles and along the outer side of the feet A few papules are present on the dorsal surface of several toes The skin is erythematous about the papules on the feet and ankles There is also diffuse acne on the forehead, which has improved with the use of 30 per cent sulfur paste The verrucous lesions have remained unchanged with local treatment and the administration of vitamin A and paraaminobenzoic acid

Histologic examination of a biopsy specimen from the left wrist showed a thick scale in which the cornified layers were interlaced Nuclei were absent except in one small area of parakeratosis The epidermis showed irregular acanthosis except for thinning beneath the parakeratotic scale At this site the granular layer was missing Elsewhere the granular layer was thickened, and in some cells there were small vacuoles The corium was edematous, and it contained a diffuse infiltration of lymphocytes, histiocytes and connective tissue cells In many places the edema and cellular infiltrate extended up into the epidermis, and the demarcation between the epidermis and corium became indistinct The Weigert stain showed the elastic fibers to be entirely missing from the upper part of the corium

DISCUSSION

DR HAMILTON MONTGOMERY, Rochester, Minn I would agree that this is an epidermodysplasia verruciformis clinically, but the histopathologic picture shows none of the features of this disorder, especially there is no evidence of vacuolization of the cells in the granular layer This histologic picture is more that of acrokeratosis of Hopf Histologically one might regard the condition also as a form of delayed epithelial nevus, using this term in the broadest sense

DR. MARCUS R CARO I think that clinically this case fits in essentially with the description of the disease in the literature Histologically it must be granted that there is here less vacuolization in the granular layer than has been described I recall also that in a patient shown before this society by Dr Weber (ARCH DERMAT & SYPH **49** 217, 1944) there was some variation from the classic picture I wonder whether we are not trying to classify the disease in these cases

on the basis of criteria that are a little bit too rigid I think that the lesions in all of these cases are forms of tardy epithelial nevi

A Case for Diagnosis Presented by DR FRANCIS E SENEAR

M S, a woman aged 75, was seen with an eruption on the arms and legs which had been present constantly for the past five years, without any appreciable change except for extension in recent years There are no symptoms The patient states that she was seen at the Billings Clinic some years ago and that a diagnosis of purpura was made She has been seen by a number of other physicians, and a variety of diagnoses have been suggested

Biopsy shows a slight degree of intracellular edema of the epidermis with liquefaction degeneration of the basal layer in several places At these sites the blood vessels were dilated and were surrounded by a loose infiltrate of lymphocytes and erythrocytes, some of the cells extending up to the basal layer Perl's prussian blue reaction did not show any iron pigment

A Case for Diagnosis (Idiopathic Multiple Hemorrhagic Sarcoma [Kaposi] or Pigmented Purpuric Lichenoid Dermatitis?) Presented by DR O H FOERSTER and DR H R FOERSTER and (by invitation) DR D M RUCH

V S, a man aged 28, is presented because of an eruption on his lower legs, feet and toes of three years' duration He stated that in 1944 the dorsal and lateral surfaces of his great toes showed a red-brown discoloration and elevated lesions The condition remained localized until January 1946, when it extended to the dorsal surfaces of his feet and toes and to the lateral surface of each ankle In June an apparent ulceration appeared on each side of his right ankle These open lesions healed in October 1946 The eruption was first observed on his lower legs in November 1946

Examination discloses a red-brown lichenoid, diffuse, small papular eruption in patches on the sides of the first three toes of the left foot and the first four toes on the right foot, the dorsal surfaces of the feet, at the bases of the toes the heels, ankles and the anterior and medial surfaces of the lower legs directly above the ankles

The result of the Rumple-Leeds test was negative Intradermal and subcutaneous tests with congo red elicited negative reactions for amyloid

The examination of the blood showed erythrocytes 6,530,000, leukocytes 12,750 hemoglobin over 18 Gm, thrombocytes 350,000, clot retraction time 1 hour and 20 minutes, coagulation time 10 minutes and 30 seconds and bleeding time 3 minutes and 30 seconds

The histologic examination of a section taken from the dorsal surface of the right foot adjacent to the toes showed moderate hyperkeratosis and a normal epidermis There was proliferation of the walls of all the vessels of the cutis A moderately dense lymphocytic infiltrate was present in the upper and middle parts of the cutis The iron stain showed a large amount of hemosiderin in the cutis

DISCUSSION

DR HAMILTON MONTGOMERY, Rochester, Minn In Foerster's case, it was difficult to make a histologic diagnosis The section showed proliferation of capillaries and some of the smaller venules Some of the capillaries were open ended, as one sees in Kaposi's sarcoma There were also apparently some lymphocytoid cells of Marchand Against a diagnosis of Kaposi's sarcoma was the diffuse uni-

A Case for Diagnosis (Erythema Bullosum? Pemphigus Vulgaris?) Presented by DR H VICTOR MENDELSOHN

A Case for Diagnosis (Macular Atrophy? Lymphogranuloma Venereum) Presented by DR FRANK C COMBES

Sarcoidosis Presented by DR H VICTOR MENDELSOHN

A Case for Diagnosis (Periarteritis Nodosa?). Presented by DR FRANK C COMBES

A D, a woman aged 35, was first admitted to the dermatologic wards at Bellevue Hospital in June 1946 presenting irregular, erythematous, urticarial lesions, widely scattered over the extremities and buttocks The lesions had first appeared approximately two weeks prior to this admission No previous history of asthma, hay fever, eczema, urticaria or other allergic manifestation was obtained Likewise, there was no family history of any allergic disorders

The eruption began with a few urticarial lesions on the thenar eminence of one hand, the wrist of the same hand and the buttocks The gradual appearance of similar lesions on the trunk and on other extremities was subsequently noted No pertinent past history was obtained The patient had undergone cholecystectomy in December 1944 for chronic cholecystitis and cholelithiasis She gave no history of having received any of the sulfonamide drugs

During July 1946, diffuse erythema, edema and doughy induration involving the left side of the face, the shoulder girdle, the upper part of the arms and the lower eyelids developed During the course of this episode, which lasted for almost one month, the patient became toxic and continued to run a temperature which ranged between 100 and 103 F Occasional vesiculobullous lesions appeared on the soles, the dorsa of the feet and the legs This acute picture disappeared gradually, and since the middle of August 1946 the patient has continued to show the present picture of a generalized, scattered urticarial eruption, with periods of exacerbation and partial remission

The urine has repeatedly shown traces of albumin and only occasional red blood cells Studies of renal function with phenolsulfonphthalein intravenously showed a 60 per cent excretion after two hours Repeated hemograms showed mild hypochromic anemia and constant eosinophilia, which has varied between 10 and 21 per cent

Examination of the stools showed no ova or parasites Intradermal tests for trichiniasis gave a delayed positive reaction after about twelve to nineteen hours Reactions to precipitin tests for trichiniasis were negative on two occasions Aspiration of sternal marrow revealed a normal picture Roentgenograms of the chest showed no infiltrations or other evidence of pathologic changes Roentgenograms of the skull and long bones revealed no abnormalities, and there was no evidence of calcification in the muscles Chemical examination of the blood showed no abnormalities with the exception of an increase in the serum cholesterol, which has ranged from 286 to 400 mg per hundred cubic centimeters

Biopsies of skin and muscle repeated on three occasions have failed to show any specific histologic picture The most recent biopsy of the skin, performed in November 1946, showed a diffuse vasculitis throughout the reticular layer of the corium and the subcutaneous tissue In addition, there appeared to be some proliferation of the intima and a granular degeneration of the walls of the involved vessels, with an accompanying pronounced perivascular infiltration which consisted for the most part of polymorphonuclear leukocytes and eosinophils

Almost the entire scalp is affected The skin presents a dull erythema, abundant scaling and crusting There are several small yellow crusts pierced by hair (scutula) and areas of atrophy with alopecia Hairs in the affected areas are dry, grayish and lusterless On the right thigh there is a small, round, erythematosquamous lesion with a minute yellow point in the center

On microscopic examination, hairs and crusts from the scalp contained Achorion schoenleini in abundance in the hair shaft and in scutula Scrapings from the focus on the right thigh showed one lanugo hair with the same fungi

The patient's mother was born in the United States Her father emigrated from Italy in 1920 There are two other children in the family A boy, aged 8, is free from infection In a girl, aged 2, a scaly lesion developed on the scalp two months ago Microscopic examination of hairs from this lesion showed fungi of favus

Fig 1—Favus of the scalp

DISCUSSION

Dr Marion B Sulzberger One must always bear favus in mind when seeing lesions of the scalp, even in patients of American birth. About twelve years ago I saw a telephone operator with favus of the scalp in mild form resembling dandruff or mild tinea amiantacea, with some involvement of several nails She was of American birth, and I do not think I would have thought of favus of the scalp if I had not examined the nails and recovered Achorion schoenleini She had been exchanging headpieces with the other girls at the telephone switchboard On questioning the mother of Dr Muskatblit's patient, I asked her if any members of the family showed signs of favus and she said there were none Then the girl herself volunteered the information that the father, who was born in Italy, had

DISCUSSION

DR GEORGE M LEWIS The features in this case, both clinical and histologic, may be interpreted to fit into the syndrome known as eosinophilic granuloma The lesions at present have undergone involution to a certain degree, and a biopsy taken at this stage might show a mixed infiltrate and not a pure eosinophilic infiltration The development of urticaria-like lesions, with subsequent disappearance and deposition of pigment, is a picture reminiscent of a patient I presented before this Section (ARCH DERMAT & SYPH **49** 375 [May] 1944), as well as before the Manhattan Dermatologic Society (ARCH DERMAT & SYPH **48** 436 [Oct] 1943) It is interesting that our patient had a Trichophyton purpureum infection of the feet, and, from the observations of Dr Cormia and myself, this case would seem to bear an etiologic relationship Inspection of this patient's feet suggested a fungous infection While not all cases of periarteritis nodosa are fatal, the prognosis is not as good as with eosinophilic granuloma, so that it would appear important to attempt to decide the diagnosis in this case by studying more histologic sections

DR CHARLES WOLF This case is unusual, and the diagnosis is difficult I was particularly impressed with a large lesion over the right pectoralis muscle which had a polycyclic border and was infiltrated There was severe itching The patient had had hemorrhagic bullae, papules, macules and all varieties of lesions that fit in with a diagnosis of mycosis fungoides I think that she bears watching for further evidence of that disease

DR FRANK C COMBES I appreciate Dr Lewis' remarks, and if a fungous infection and hyperergy can be substantiated in this patient they may explain the periarteritis The bullae seen on the feet tonight were not there a week ago She has had recurrent bullae, however, not only on the soles but on other parts of all extremities Examination of the walls and the contents of the lesions did not reveal fungi I do not know what the results of the trichophytin test were Periarteritis nodosa does not seem to be the rare disease originally described with a mortality in excess of 90 per cent In 1937 a comparatively benign chronic form was described (Carol, W L L, and Prakken, J R *Acta dermat-venereol* **18** 102-118 [Feb] 1937), and we have seen several patients recently who might be considered to have this type If the disease is interpreted as an allergic manifestation, it might be the result of a mycotic infection I do not know Sensitization to Bacillus coli has been indicated in some previous reports This patient underwent a cholecystectomy in 1944, which may bear on the origin of her present disease There was no histologic evidence of dermatomyositis but extensive nodal periarteritis throughout the reticular layer of the dermis and in the hypodermis, accompanied with a notable perivascular infiltration consisting essentially of polymorphonuclear cells and eosinophils The constant high eosinophil count of the blood, ranging from 10 to 20 per cent, is indicative of hyperallergization I am not prepared to say whether this patient has early eosinophilic granuloma, as I have never observed an early case of this disease

A Case for Diagnosis (Epidermolysis Bullosa?) Presented by DR EMANUEL MUSKATBLIT

Palmar and Plantar Keratoses (Arsenical?) Presented by DR MAURICE J COSTELLO

a deformed fingernail I think it would be worth investigating to find whether there is a focus there I hesitate to suggest any therapy on such scant evidence, but Dr Loeb at our clinic used a preparation called dermycin® (para-nitrophenol–sodium iodate solution) which had been submitted for trial He treated 1 patient with favus of the scalp which had recurred after two roentgen ray epilations

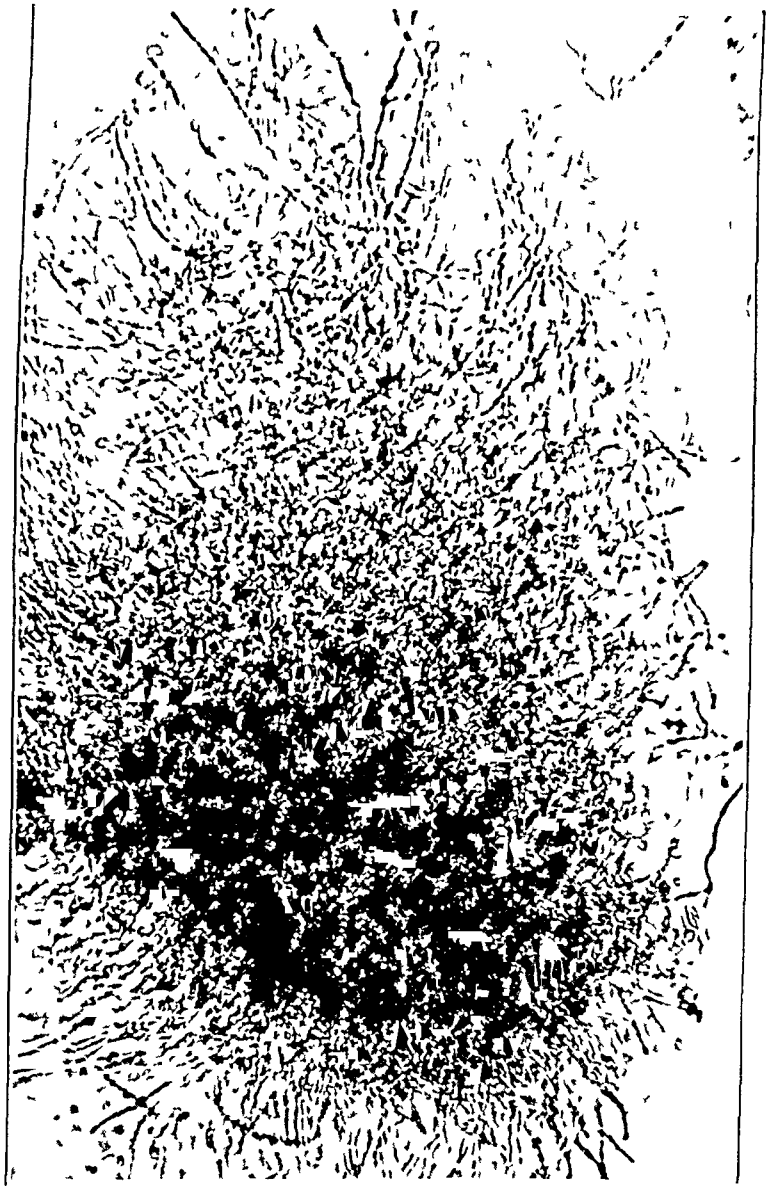

Fig 2—Achorion schoenleini in a scutulum from the scalp Potassium hydroxide preparation, × 300

with perfect results in a relatively short time Perhaps this preparation is worth trying in this case I shall be glad to see that Dr Muskatblit gets some dermycin® if he wishes to try it

Dr George M Lewis We had a patient a few years ago who had favus of the toe nail In the investigation of possible lesions in the family, the feet should

Trichophyton Violaceum Infection of the Scalp Presented by DR FREDERICK REISS

S G, a white boy aged 8, is presented from the Dermatologic Clinic of Bellevue Hospital with lesions of the scalp of four months' duration

Shortly after the patient's arrival from Greece about four months ago, small areas of alopecia were noted on the scalp These fluoresced poorly under the Wood light, and some patches had few, but noticeable, "black dots"

Potassium hydroxide preparation showed spores situated inside the hair shaft A culture on Oct 10, 1946, was sterile Culture on November 13 yielded Trichophyton violaceum

DISCUSSION

DR EMANUEL MUSKATBLIT This condition is relatively rare in the United States Such cases may escape attention when, as in this instance, there are few foci, probably a quarter of an inch (0 64 cm) in diameter, which do not show the typical broken hairs In such instances the condition may not be revealed by examination under the Wood light This case will probably require epilation with roentgen rays, and even with that the infection may not be easy to eradicate

DR GEORGE M LEWIS In Russia, Trichophyton violaceum is one of the common pathogens One of our recent visitors to this country confirmed that fact and showed me pictures of some of the generalized eruptions as well as of typical involvement of the scalp and nails I can attest to the difficulty of curing the patients They are apt to pass from clinic to clinic, they receive roentgen ray epilation in a clinic that performs epilation well, and then several foci will be found to have been left, and it is difficult to say how they escaped treatment Dr Fox, if he were here, would probably comment on a patient who had had three epilations It was a considerable time after the last epilation before the hair returned The condition finally cleared One must be careful, in considering roentgen ray epilation in these patients, to ascertain whether epilation has been done previously

DR FREDERICK REISS The point which Dr Lewis brought out about the wide dissemination of such cases in Russia is interesting, but there is another remarkable point In Russia, T violaceum was frequently the cause of a deep-seated inflammatory reaction, while this fungus according to our experience causes only superficial involvement

Extensive Pigmentary Changes Following Bismuth Therapy Presented by DR MAURICE J COSTELLO

Herman Sharlit, M D, *Chairman*

Maurice J Costello, M D, *Secretary*

Feb 4, 1947

Darier's Disease in Mother and Daughter Presented by DR SAMUEL M PECK

Granuloma Inguinale with Extragenital Lesion on the Cheek Presented by DR MAURICE J COSTELLO

DISCUSSION

DR MAURICE J COSTELLO It was interesting to note that this patient was presented at another dermatologic society the other night without a complete history, and the consensus of those present was that she might have scrofuloderma This

not be overlooked I believe that the patient should receive roentgen ray epilation without delay The longer the process is allowed to go on, the more danger of further dissemination Roentgen ray treatment would appear safe in this case, although I do not believe a patient should have a third epilation without careful consideration I doubt if local therapy is worth attempting, and I would be against experimentation when we know that local therapy is not effective When

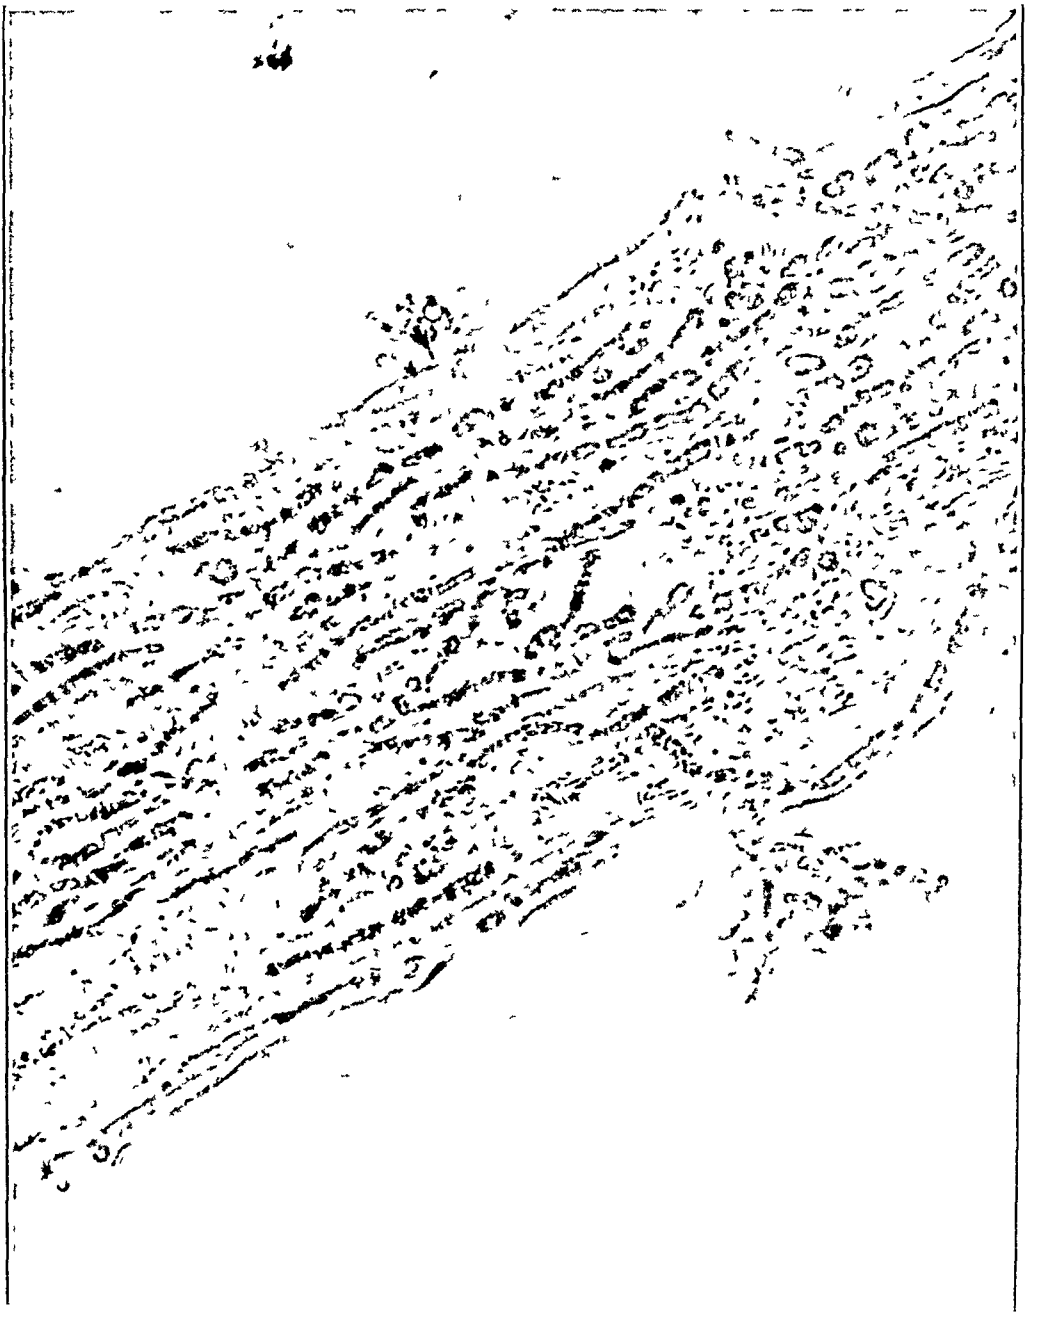

Fig 3—Achorion schoenleini in a lanugo hair from the thigh Potassium hydroxide preparation, × 770

I was examining this child, two of the younger men in the audience commented that they rather doubted the diagnosis because there were no scutula present I stated that we should censure Dr Muskatblit if the patient were presented with scutula The first step is to institute a good hygienic regimen to get rid of the bulk of crusts and scaling on the scalp before the roentgen rays are administered

confirms what Dr Chargin said, that one seldom if ever thinks of granuloma inguinale as having extragenital lesions, although I understand that the lesion in the first case ever described was extragenital I agree also with Dr Sobel I have seen several patients at Bellevue Hospital in whom the lesions began as enlarged inguinal lymph nodes, broke through the skin, and then took on the characteristics of granuloma inguinale in which Donovan bodies were found In this case Donovan bodies were found in the lesions on the neck and in the groin It would not surprise me if they could be found in the enlarged lymph node also, as suggested by Dr Bloom

A Case for Diagnosis (Lichen Planus) Presented by Dr William Leifer

Actinomycosis Simulating an Abscess Presented by Dr Emanuel Muskatblit

M A, a girl aged 17½, presents an inflammatory mass in the left mandibular area of three and a half months' duration The lesion is fluctuant and tender and discharges a grayish green, purulent material from its lower pole In October a decayed left lower molar was extracted Several weeks later a "lump" appeared which was believed to be an abscess This was incised and drained twice, with little evidence of healing The patient received ultraviolet irradiations for a while During the first week in January the cause of the disease was discovered when the granules in the pus were examined and the ray fungus of actinomycosis was seen in the fresh specimen as well as in the Gram stain Results of cultures have not yet been reported

To date the patient has received approximately 6,000,000 units of penicillin with noticeable improvement

DISCUSSION

Dr Nathan Sobel I was interested in the improvement with penicillin I understand that while penicillin is effective in most cases, some cases prove resistant to this form of therapy

Dr Emanuel Muskatblit The patient was hospitalized for a few days in one of the large hospitals, where the lesion was incised and drained, but it did not heal A few weeks later it was again incised and drained, and the patient was kept under observation for two and a half months, without any one's looking at a drop of pus under the microscope Regular surgical treatment did not have the regular effect, and there was a history of a bad tooth in addition

There is no scarring, no hardening and no typical sinuses It looks like an abscess It is confined to the skin and subcutaneous tissues, and there is no evidence of involvement of the deeper tissues Diagnosis from laboratory examination was surprisingly easy in this case Three weeks ago, every drop of pus, which could be obtained easily, showed the presence of granules which were visible in unstained preparations and also with the Gram stain The patient was given penicillin, 50,000 units every three hours, day and night 100,000 units per day She has now had 6,000,000 units or more During the last few days there has been considerable improvement The central area subsided and no more pus discharged—just a little serum and blood It is planned to continue until 10,000,000 units has been administered, and probably sulfadiazine and possibly potassium iodide will be given Roentgen therapy has been deferred because the dosage would have to be large, with high voltage, and because of the possibility of its producing radiodermatitis on the face

DR EMANUEL MUSKATBLIT The scalp should, of course, be cleaned with some desquamating preparation to dissolve all scales and crusts and the hairs cut short, almost level with the skin, before epilation If scales, crusts and long hairs are left, we will not get the roentgen rays close enough The suggestion to examine the family is excellent It is possible that the father has favus of the nails As far as Dr Sulzberger's remark about trying a new chemical is concerned, I agree with Dr Lewis It would be pretty hard to try a new chemical in such an extensive case I should like to try it on the patient's sister, who has only a small patch I agree that roentgen therapy is now perfectly safe if we know definitely that no more than eight subfractional doses were given

A Case for Diagnosis (Lupus Erythematosus? Erythema Solare?) Presented by DR MAURICE J COSTELLO

Lupus Vulgaris Improved from Treatment with Calciferol (Vitamin D_2) Presented by DR FRANCES PASCHER and DR JESSE A TOLMACH

Lichenoid and Miliary Sarcoid (Boeck) in a Negro Woman Improved After Treatment with Calciferol (Vitamin D_2) Presented by DR MAURICE J COSTELLO

DISCUSSION

DR MARION B SULZBERGER We have overwhelming evidence from many countries, including the United States, that calciferol should not be withheld in any case of sarcoidosis, scoruloderma, tuberculosis colliquativa or other tuberculoderm, unless it is contraindicated Many cases of sarcoid appear to respond well to this treatment, which lends some support to the theory that it is a form of

Superficial Epithelıomatosıs Presented by Dr S Irgang

C S, a white woman aged 55, is presented from Harlem Hospital with an asymptomatic eruption which was first noticed sixteen years ago This appeared as a single lesion on the left arm, followed two years later by another on the small of the back Other lesions developed slowly, so that at present they are on the back, left arm, left flank and face The majority of lesions on the right cheek are nevi

The eruption consists of dry, nonulcerated nodules and plaques The former are firm, smooth, elevated, mildly hyperpigmented and/or pinkish, glistening lesions varying in size from that of a pinhead to that of a split pea, while the latter consist of slightly infiltrated, superficial, well defined, pinkish or reddish, flat, slightly depressed, scaly lesions with pearly, threadlike borders and varying in size from that of a split pea to that of a dime Thirty-seven years ago the patient took orally a clear, liquid medication in drop dosage for nine months and again twenty-four years ago for a two week period On each occasion it was discontinued because of intolerance There are no cutaneous evidences of either arsenical hyperpigmentation or arsenical keratosis Histologic examination shows the typical picture of basal cell epithelioma

DISCUSSION

Dr David Bloom This patient gives a history of having received drops for acne vulgaris at the age of 18, administered during a period of eight months This was probably arsenic, and I suspect that her epitheliomatosis is a result of the arsenic ingestion

Dr Samuel M Peck We are not sure the patient received arsenic, and if one wishes to speculate on such a causal relationship, one would expect palmar and plantar keratoses A patient may take potassium arsenite solution (Fowler's solution) for no more than a few weeks or months, and twenty years later keratoses and epitheliomas may develop

Dr Herman Goodman Hundreds of thousands of persons have been given potassium arsenite solution in increasing dosage from 1 drop to 15 drops or more, three times daily, with no great number of them having superficial epitheliomas Pharmacologically, arsenic is a producer of keratin, it has been an ingredient in certain applications to the scalp as a hair grower Before the era of roentgen ray treatment for psoriasis, arsenic was given to patients with that disease In a few of them epithelioma developed on the site of the psoriatic patches A search of the literature disclosed that Arthur Alexander in 1920 assembled 18 patients with carcinoma of the skin together with psoriasis Of these, the disease in 11 was considered as malignant degeneration of arsenical hyperkeratosis or arsenical carcinomas on a psoriatic basis In the remaining 7 the lesions were considered as psoriatic carcinomas

Arsenic does foster the proliferation of epithelium, it is a keratoplastic agency It may cause the overgrowth of epithelium recognized clinically and under the microscope as epithelioma

Dr Samuel M Peck I still believe that one of the best therapeutic measures in the treatment of psoriasis is arsenic, given properly From the statistics of the incidence of epithelioma, one finds that most of the patients never received arsenic, unless food is a possible source Persons who have never been exposed to arsenic have just as much if not more epithelioma than those who have received moderate doses of potassium arsenite solution I do not mean that treatment should continue for twenty years Therefore, in presenting this case with arsenic as a possible

tuberculosis At the beginning we were careful to duplicate exactly the sterogyl 15® preparations used by Charpy and others, who emphasized that it was essential to give vitamin D_2 in alcoholic solution We now think this may not be necessary as our patients treated with ertron,® davitol,® etc, do as well as those given the alcoholic solutions The American preparations just mentioned are readily available here, whereas the alcoholic solutions are not

Follicular Atrophoderma of Body and Scalp, Chondrodystrophia Calcificans Congenita Presented by DR HELEN O CURTH

Lupus Vulgaris Successfully Treated with Calciferol (Vitamin D_2) Presented by Dr MAURICE J COSTELLO

Sarcoid of Boeck Presented by DR S IRGANG

Epithelioma Presented by DR MAURICE J COSTELLO

M G, a woman aged 84 from Lenox Hill Hospital, presents a "browsing" type of basal cell epithelioma involving the forehead, cheeks and nose It consists of nodular, waxy, shiny, ulcerating, infiltrated strands of epitheliomatous tissue involving these areas There is some distortion of the nose, especially in the region of the right ala nasi This patient has received an incredible amount of roentgen rays according to the Coutard technic to a number of the affected areas on the face during the past six years Because of the age and infirmity of the patient, the treatment has been palliative

DISCUSSION

DR CHARLES WOLF I wonder whether there was not a previous disease here, later developing into epithelioma, for example, syphilis, although her Wassermann reaction may be negative at present Epithelioma does not generally extend the way this one has It is of the ulcerative type when it becomes so extensive This has the clinical appearance of the morphea-like or scleroderma-like epithelioma which generally follows a previous disease

Dermatitis Herpetiformis (?) with Mucous Membrane Involvement and Nail Changes Presented by DR FRANCES PASCHER

P R, a woman aged 42, born in Puerto Rico, is presented from the New York Skin and Cancer Unit complaining of recurrent attacks of "blisters" on the body and in the mouth for the past year These lesions are preceded by burning and pain The patient denies the ingestion of drugs

The patient presents a multiform eruption on the trunk made up of erythematous macular and urticarial lesions varying in size and shape There are also some thin-walled bullae on a noninflammatory base, with gyrate patches of pigmentation, atrophy and scarring There is a hypertrophic scar on the right shoulder Bullae followed by superficial ulceration also appear on the lateral edges of the tongue and buccal mucosa, and leukokeratotic changes are seen in the mouth The Nikolsky sign is strongly positive The nail changes include thinning and separation of the nail plate and subungual hyperkeratosis The neurologic examination is entirely normal

Biopsy of one of the bullous lesions showed a bullous eruption, with no definite diagnosis possible, and no defect in the elastic tissue Reactions to potassium iodide and potassium bromide were inconclusive, since the skin separated with the least

causative agent, one should be cautious If, with the epitheliomas, there were typical hyperkeratoses on the palms and soles, and if, in addition, the patient had been taking potassium arsenite solution for many years, it would be more plausible to consider arsenic as a causative factor I would not hesitate to prescribe arsenic in lichen planus or psoriasis, because of the remote possibility of the development of epitheliomas Patients who have taken potassium arsenite solution for many, many years are those in whom keratoses and malignancy growths develop

DR MARION B SULZBERGER I do not agree with Dr Goodman that, because thousands of patients who take a drug have not had manifestations, the drug can be exonerated as a possible cause of trouble in a given case If that were a valid argument, one would conclude that the proved reactions from phenolphthalein, the barbiturates, antisyphilitic arsenicals, salicylates and the like were not due to those drugs because hundreds of thousands of persons have taken them with impunity I think it correct to start the other way around and ask how many persons with multiple benign epitheliomas have had therapy with arsenicals or exposure to arsenicals If one questions these patients carefully, one finds that a surprisingly large percentage have had exposure to inorganic arsenicals and an exceptional patient has had exposure to an organic arsenical The history of exposure in these cases is so high that it cannot be due to chance, so it is permissible to conclude that the lesions in some cases must be due in some way to arsenic I do not mean that all multiple superficial benign epitheliomas are due to arsenic But arsenic is not completely exonerated even in those cases without therapeutic exposure, because occult exposure is practically universal These lesions occur not only after larger amounts of the drug are given, but sometimes also after small amounts I agree with Dr Peck, on the other hand, that this is no reason for withholding a valuable drug Most of these conditions are benign, and the complications are rarely dangerous Moreover, the incidence of these disagreeable by-effects is very small, considering the large number of persons who have been exposed to arsenic Therefore, if arsenicals are valuable drugs, there is no reason for withholding them, provided that the indications are clearcut, even if it is established that benign epitheliomas are due to arsenic However, the dosage should be correct and no unnecessary risks taken Every patient receiving arsenic should be under constant medical supervision, and every prescription for arsenic should therefore be marked "no repeats"

DR DAVID BLOOM Years ago I presented from Bellevue Hospital the case of a woman who had received arsenic for psoriasis over a period of three years and in whom typical arsenical keratosis developed on the palms and soles with basal and prickle cell epitheliomas on the body

Granuloma Inguinale, Sickle Cell Anemia with Sickle Cell Ulcer of the Ankle Presented by DR SAMUEL M PECK

DISCUSSION

DR SAMUEL M PECK Here, instead of a thrombosed varicose vein and lack of a proper blood supply, there is actual thrombosis of a blood vessel due to sickle cell thrombi One of the methods of treatment I have tried which has resulted in fairly rapid improvement was keeping the patient in bed for months at a time, taking her blood serum and adding penicillin, and applying it locally as a dressing I allowed this to remain on for a period of four or five days before changing, and there was an amazing response, not only in the secondary infection as one would

trauma In three examinations of the blood the eosinophils did not exceed 10 per cent The bulla fluid was free of cells Results of serologic tests for syphilis were negative The urine was normal, and the basal metabolic rate was —11 per cent

Some improvement followed one course of treatment with potassium arsenite (Fowler's) solution, and a remission took place when therapy was discontinued Multiple vitamins have been taken three times daily over a period of months without apparent change Treatment with sulfapyridine is contemplated

DISCUSSION

DR FRANK VERO In spite of the biopsy, I think that a diagnosis of epidermolysis bullosa should be considered because of the nail changes, oral lesions and the atrophic changes and scarring on the back

DR DAVID BLOOM I believe that pemphigus should be considered, and onycholysis may be part of the eruption I do not recall having seen a case of dermatitis herpetiformis with such extensive eruption in the mouth

DR FRANCES PASCHER This patient presents a problem in differential diagnosis I do not know how one can say with finality what type of bullous eruption this might be, but I did consider all the bullous eruptions, such as epidermolysis bullosa, possible lichen planus and bullous Hansen's disease I considered the possibility of erythema multiforme bullosum, but this diagnosis was excluded because of the gyrate configuration of the patches, atrophy and pigmentation Most of the features fit in best with a diagnosis of dermatitis herpetiformis rather than the other eruptions

Hodgkin's Disease Treated with Nitrogen Mustard Presented by DR T J RIORDAN

E B, a man aged 20, is presented from St Vincent's Hospital In August 1945, there was enlargement of lymph nodes in the neck This was treated with roentgen rays In August 1946, a cluster of small papules appeared in the left axilla These persisted, grew progressively larger, coalesced and ulcerated Roentgen therapy had no effect In December, after nitrogen mustard therapy, the lesions regressed greatly In March 1947, the lesions again enlarged, reddened and drained Nitrogen mustard and roentgen therapy were again administered, and pronounced improvement followed, this has continued to date

DISCUSSION

DR A ROLLINO (by invitation) The usual cutaneous lesions observed in Hodgkin's disease are pigmentation, excoriations due to scratching and herpes zoster In a series of 75 cases of Hodgkin's disease my co-workers and I have encountered 3 patients with skin lesions similar to those demonstrated here, they appear in clusters of small nodules—in 2 cases on the chest and in the third in the axilla When the lesions first develop, they simulate pyoderma or a deep-seated vesicle They persist and may coalesce and ulcerate Biopsy establishes the diagnosis In the case demonstrated, roentgen therapy did not effect the lesion, but the response was spectacular to nitrogen mustard therapy The improvement lasted about three months, after which the lesions reappeared, grew larger and began to weep, itch and grow painful Again nitrogen mustard therapy was resorted to, and the lesions have almost cleared up

DR. DAVID BLOOM I should like to ask the presenter about the swellings of the right clavicle It seems to me there is involvement of the bone itself

expect, but in closure of the lesion Another feature is the pronounced anemia The patient was hospitalized mainly because of the very low blood cell count—as low as 30 per cent and often 50 per cent of normal

Eczema Verrucosum of the Legs Presented by DR LEWIS A GOLDBERGER

A Case for Diagnosis (Pemphigus? Bullous Eruption Due to Drugs?) Presented by DR LEWIS A GOLDBERGER

Multiple Benign Cystic Epithelioma Presented by DR S IRGANG

O D, an 8 year old Negro boy, has an eruption which was first noticed on both lower eyelids about a year ago The eruption is generalized, symmetric and nonpruritic and consists of pinpoint-sized to pinhead-sized firm, smooth, discrete, slightly elevated, flesh-colored and mildly hyperpigmented lesions, showing no tendency toward grouping The circular hyperpigmented area below the right jaw represents the end result of a recent fungous infection The child's mother has a similar eruption limited to both lower eyelids Histologic examination of lesions from the chest and right lower eyelid show the features of multiple benign cystic epithelioma

DISCUSSION

DR DAVID BLOOM Such lesions as the patient presents on his body are frequently seen in Negroes Recent histologic examination in such a case showed keratosis pilaris, mild keratosis extending also between the follicles However, the lesions on the face of this patient suggest the diagnosis as presented I am therefore inclined to consider that this patient has two kinds of lesions

DR NATHAN SOBEL I think that perhaps another pathologist would describe the eruption as syringoma, because that is closely related to benign cystic epithelioma and they may even simulate each other (Ingels, A E Epithelioma Adenoides Cysticum with Features of Syringoma, ARCH DERMAT & SYPH **32** 75 [July] 1935) It is the first case I have seen in a child I have seen a number of patients with the generalized syringoma type, but those I have seen occurred later in life, in the twenties or thirties

DR S IRGANG I agree with Dr Rosen that this disease is relatively rare in male subjects and it does not occur in so young a person Clinically, the lesions on the lower eyelids resembled multiple benign cystic epithelioma, but the others simulated micropapular tuberculid Histologically the lesions on the chest had to be differentiated from syringocystoma, but the latter was ruled out because the cells were evidently derived from the basal cell layer

Herman Sharlit, M D, *Chairman*

Maurice J Costello, M D, *Secretary*

March 4, 1947

Fixed Eruption Around the Mouth Due to Phenolphthalein or Bubble Gum? Presented by DR WILLIAM CURTH

DISCUSSION

DR WILLIAM CURTH There are various ingredients in bubble gum—cane sugar, corn sugar, cornstarch, a trace of vanillin, coumarone resin, oil of orange as a flavoring and oil of cinnamon, which is the main flavor Oil of cinnamon

DR A ROTTINO (by invitation) Yes, the clavicle is involved In no instance has the cutaneous involvement been primary, but it has been preceded by lymph node involvement The diagnosis in each case was established before the cutaneous lesions appeared

Kaposi's Sarcoma Presented by DR MAURICE J COSTELLO

A M, an Italian man aged 75, from the Lenox Hill Hospital Outpatient Department, in the early part of 1941 presented a soft, compressible, telangiectatic, marble-sized lesion on the right palm which was thought to be a pyogenic granuloma The lesion was destroyed by surgical diathermy but recurred with a number of satellite miniatures of the mother lesion Since that time numerous other lesions have appeared and are still present on the forearms, legs and thighs At present there are discrete, grouped, coalescing, purplish, globular, noncompressible, somewhat painful lesions on the legs and thighs, interfering to some extent with the venous circulation and causing brawny edema of the legs and feet There are a number of small warty excrescences on the dorsal aspect of the toes The axillary lymph nodes are enlarged Microscopic examination revealed the surface to be covered with stratified squamous epithelium surmounted by thick layers of keratinized, partially calcified material In a small area the surface epithelium was broken and missing Here and there exposed stroma showed fibroblastic proliferation and was rich in dilated small blood and lymph vessels A dense infiltration of inflammatory cells, chiefly round cells, was seen The electrocardiogram was normal

The disease has been well controlled with low, medium and high voltage roentgen rays The left palm received 1,000 r and the left axilla 1,200 r Two per cent sodium arsenate solution was administered by hypodermic injection at regular intervals, but was inferior to roentgen rays in therapeutic effect

DISCUSSION

DR DAVID BLOOM Two of my patients with Kaposi's sarcoma were treated with antireticular cytotoxic serum of Bogomolets but failed to respond

A Case for Diagnosis (Trophic Changes in the Legs and Feet Following Freezing) Presented by DR MAURICE J COSTELLO

Vaccination "Take," Left Index Finger Presented by DR TIMOTHY J RIORDAN

B D, a physician's office nurse, while assisting in numerous vaccinations two weeks ago, accidentally sustained a puncture wound from the virus capillary tube on the lateral aspect of the volar pad of the left index finger (fig 1)

Idiopathic Multiple Hemorrhagic Sarcoma (Kaposi) Presented by DR TIMOTHY J RIORDAN for DR ANTHONY ROTTINO

G M, a man aged 57, Italian, had Kaposi's disease for two and a half years Pathologic examination of a mass in the pharynx, lingual and tonsil area, removed in November 1946, and a biopsy of a cutaneous lesion, corroborated the diagnosis Treatment with seventy injections of nitrogen mustard was ineffectual

The patient was critically ill on admission to St Vincent's Hospital on Feb 25 1947, with evidence of ascites, gastrointestinal hemorrhage and peripheral

has caused cheilitis in some cases, but there is no case on record of pigmentation or fixed eruption due to oil of cinnamon

Pemphigus Erythematosus (Senear-Usher Syndrome) Treated with Vitamin A, Erythroplasia of Queyrat *Presented by* DR FRANK VERO

J W, a Russian Jew aged 73, is presented from the Vanderbilt Clinic with an eruption on the face, trunk and extremities of sixteen months' duration and a lesion on the penis which has been present for five years

In 1944, after an attack of hematuria, a diagnosis of papillary carcinoma of the bladder was made It was treated by fulguration, and there has been no recurrence since September 1944 At that time a penile lesion was discovered, which had been present since 1942 This affected the glans, corona and sulcus

Late in 1945 small vesicles appeared on the sternum and quickly ruptured From then on, new lesions have appeared on the chest, arms, back and abdomen, and six months ago they spread to his face These lesions ruptured spontaneously, and soon became covered with a rather heavy, greasy scale He experienced little pruritus He denied the use of any drugs

Examination on admission showed dull erythematous patches, varying from 3 to 7 5 cm in diameter Intact bullae were present, these were about 1 cm in diameter and flaccid Most of the lesions were covered with gray-brown, greasy scales which were readily separable Heavy crusting was most apparent on the back and chest Two weeks later the small lesions on the right cheek had spread to cover both cheeks in butterfly shape A positive Nikolsky sign was elicited at this time on the patient's back On the glans penis, extending to the sulcus, there was a well defined, dull red, eroded and infiltrated lesion, measuring 1 5 by 2 cm, with a leukoplakic patch near the frenulum praeputii

A blood cell count showed 13 0 Gm of hemoglobin, 4,810,000 red blood cells and 5,500 white blood cells, with 68 polymorphonuclear leukocytes, 31 lymphocytes and 1 eosinophil

The serum cholesterol was 300 mg per hundred cubic centimeters and the serum protein 7 2 mg The albumin was 5 0 mg per hundred cubic centimeters, globulin 2 0 mg and nonprotein nitrogen 33 mg The cephalin flocculation test gave a negative reaction

Biopsy of material from the upper region of the right arm revealed a moderately acanthotic and edematous epidermis, with fairly prominent rete pegs in the central portion but with a flattened cutiepithelial line of juncture elsewhere No bullae or vesicles were seen in the section, but in their central portions were seen areas suggesting the "corps ronds," "grains" and space formation similar to those seen in Darier's disease, Hailey and Hailey's benign pemphigoid and pemphigus foliaceous The corium was edematous, particularly in the region of the pars papillaris, the capillary vessels were engorged and surrounded by a considerable perivascular infiltrate of round cells In view of the clinical picture, it was felt that a diagnosis of pemphigus erythematosus was justified

Biopsy of material from the prepuce showed an elongated, rectangular piece of tissue composed of loosely bound, fibromatous bundles, numerous blood vessels and lymphatic vessels and mucosa which presented a number of interesting changes in several areas There was an infiltration with lymphocytes, plasma cells and round cells in the subcutaneous tissues throughout their entire length, but it was most pronounced wherever the epithelium was thickened In such places the infiltration was massive The capillaries were numerous Where the epidermis was thickened there was also dyskeratosis The stratum granulosum was indistinct The most notable change was in the prickle cell layer Here the cells

Fig 1.—Vaccination "take" on the index finger

appeared fused, with absence of intercellular bridges The nuclei were pale and irregular, but they were hyperchromic There was considerable edema Some cells were large and vacuolated, and in one area were seen cells resembling Paget cells The infiltration with lymphocytes was pronounced The basal layer was indistinct Mitosis was present

Potassium permanganate baths were prescribed Sulfapyridine, 0 5 Gm four times daily, was taken from October 1 to November 6 A slight improvement was noted after one week of treatment, but it then ceased Carbarsone, 0 25 Gm four times daily, was given from November 6 to December 8, with questionable improvement The administration of vitamin A, 200,000 units daily, was begun on December 4 and has continued up to the present, and vitamins in the form of a therapeutic formula have also been taken during this period By Jan 15, 1947, there was remarkable improvement of the lesions, and by February 10 only the pigmented residua were found

The patient refused surgical therapy for the penile lesion

DISCUSSION

Dr Beatrice M Kesten Tonight I think it would be difficult to confirm the diagnosis, but when we saw the patient in December it was one of the most typical examples of the Senear-Usher syndrome that we have encountered

Dr Fred Wise The concurrence of two different types of dermatosis in this patient is of particular interest The eruption on the trunk appears to conform to the Senear-Usher dermatosis, and the diagnosis of erythroplasia of the penis has been confirmed by the microscopic examination It is of course interesting to speculate on the possible pathogenic relation between the two eruptions

Dr Gerald F Machacek This patient was shown by me last October, and at that time there was present a typical Senear-Usher syndrome The lesions of the body followed the neoplastic lesion on the penis In fact, he had another neoplasm, for which he has been operated on several times—a papillary carcinoma of the bladder, with presumptive cure The histologic picture of the penile lesion was epithelioma in situ The other lesions at that time were typical

Dr J Gardner Hopkins I think Dr Vero was interested in presenting this case because of the patient's response to treatment We cannot be sure that the result is due to the treatment given, but the change in the appearance of this man has been striking It came after a course of carbarsone during which he had shown no visible improvement Dr Vero employed this particular therapy because of the more evident response to vitamin A in a somewhat similar case

Dr Frank Vero I cannot explain the rationale of vitamin A therapy and the result obtained I treated another patient with pemphigus (Senear-Usher type), a 76 year old patient who had had the disease for three years She had had day and night nurses and all kinds of therapy including penicillin, bismuth, iodides and vitamins, without results or with only a temporary improvement In September 1946 she had keratoderma of the feet and subungual hyperkeratosis I prescribed 100,000 units of vitamin A daily, and within three to four weeks all her lesions healed The patient is able to go out daily She has gained weight, and for the past two months my services have not been needed It is interesting that this patient has had a poor appetite all her life, so that her food had to be actually forced on her

edema Roentgen examinations revealed intraluminal masses and obstruction On March 17 operation was performed in an attempt to relieve the obstruction and control the hemorrhage The patient died five days later

A Case for Diagnosis (Keratosis Blenorrhagica? Psoriasis?) Presented by DR MARION B SULZBERGER for CAPT C D BELL and DR LIONEL RUBIN

F G, a white man aged 22, first became ill in September 1946 At this time severe pain developed in the right hip, without apparent cause, which forced the patient to stop work This was shortly followed by similar pain in the right shoulder and scapular areas and on both sides of the chest He was then acutely ill, his temperature rising as high as 101 F in the afternoon The smaller joints of the extremities, including the wrists and ankles, also became painful In October the right great toe nail became tender and elevated, accompanied by pain and swelling of the dorsum of the foot The toe nail was removed by an osteopath, with no improvement At the same time the patient had iritis of the right eye, and he was now so ill that he was admitted to the United States Naval Hospital, St Albans N Y He had lost 30 pounds (14 Kg)

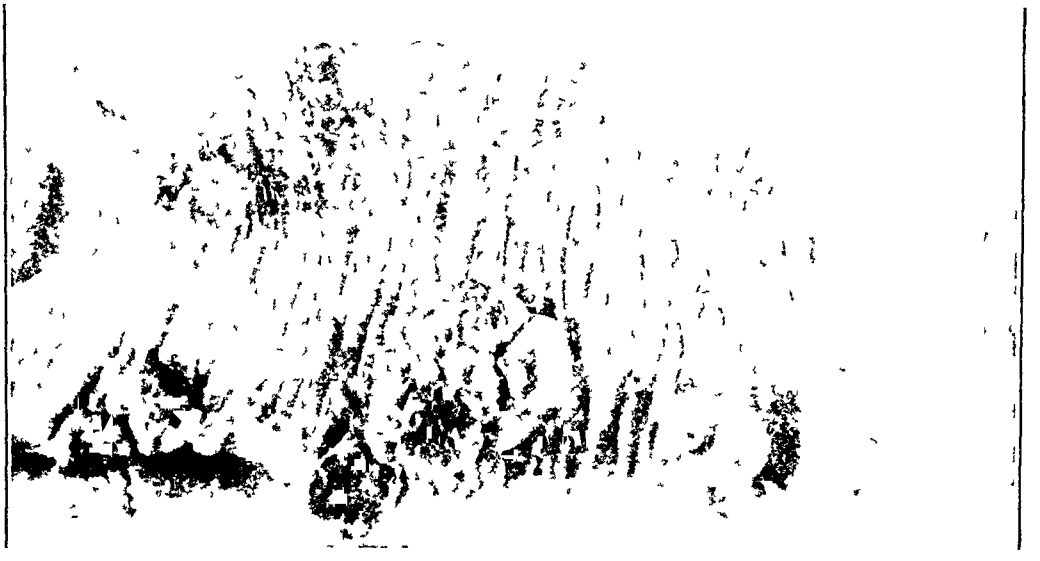

Fig 2—Gross pathologic specimen of intestinal section

The admission examination on November 18 revealed a dilated right pupil with posterior synechial pigment deposits on the lens and a cloudy aqueous blurring the fundus There were erosions on the tongue, buccal mucosa and palate and there was a discrete, papular eruption of the skin of the genitalia and inner aspect of the thighs "resembling scabies" The right scapula, left wrist, lumbar spine, right hip and right ankle were tender on pressure and painful on motion but exhibited no local heat, redness or swelling It was also noted that there was "an infected right great toe with associated cellulitis of the right foot" Otherwise the results of physical examination was normal, and, as the impression was that he had acute rheumatic fever, he was assigned to the medical service The erythrocyte sedimentation rate was 22 mm per hour, white blood cells 12,500 with polymorphonuclear leukocytes 73 per cent and lymphocytes 20 per cent, red blood cells, 4,300,000 and hemoglobin 12 5 Gm Blood cultures were negative

While on the medical service the patient continued to have a spiking afternoon temperature varying from 99 to 101 F The iritis cleared slowly with treatment, although some permanent dilatation of the pupil remained He received 6

A Case for Diagnosis (Keratosis Pilaris? Lichen Scrofulosorum?) Presented by Dr F Philip Lowenfish

A Case for Diagnosis (Hemangiopericytoma?) Presented by Dr George C Andrews

J J M, an American student aged 18, first noticed a small "pimple" just inside his left naris about one year ago This tumor has continued to grow and is painless About five weeks ago his physician punctured the mass with a needle, which caused it to bleed a great deal

A single pea-sized, moderately firm, erythematous cystic nodule is present just within the left nasal orifice on the medial anterior aspect

The Wassermann reaction of the blood was negative, and the blood count was normal Biopsy has not yet been performed

DISCUSSION

Dr Charles Wolf These banal lesions are deceptive at times, the most innocent-looking lesions have turned out to be highly malignant In this case, I am of the opinion that it is a benign lesion I would favor granuloma pyogenicum

Dr Gerald F Machacek *On the clinical basis, I agree with the diagnosis* It is a site where hemangiopericytomas frequently occur Definite diagnosis must await examination of biopsy material

Dr Fred Wise The location and clinical appearance are in favor of the diagnosis of hemangiopericytoma A young boy seen at the Skin and Cancer Unit had a lentil-sized, slightly elevated, pinkish papule on the middle of the upper lip After complete desiccation it recurred and a tumor formed, spreading peripherally and into the deeper tissues It required an extensive radical operation on the upper lip, which I believe was performed by Dr Arthur Purdy Stout

Leprosy (Tuberculoid Type) in a Puerto Rican Man Aged 72 Presented by Dr A Benson Cannon for Dr Charles Lincoln

A Case for Diagnosis (Multiple Keloids? Dermatofibrosarcoma Protuberans [*Hoffmann*]?) *Presented by Dr George C Andrews*

Favus of the Scalp and Glabrous Skin Presented by Dr Emanuel Muskatblit

V V, a white girl aged 13, born in the United States and living in Belleville, N J, is presented from the New York University Skin Clinic

The disease of the scalp began four years ago with a scaly lesion which was diagnosed as psoriasis and treated with various ointments, ultraviolet irradiation and roentgen rays (eight roentgen ray treatments were given at weekly intervals from June to September 1946) The disease proved resistant to treatment and gradually progressed until it reached the present state During these four years the hairs from the scalp have been examined six times, and it has been reported each time that they did not show fungi The patient also had several red and scaly lesions on various parts of the body These lesions disappeared without treatment *Only one focus, on the right thigh, has persisted for the last two months*

Gm of sulfadiazine daily for two weeks, followed by 6,000,000 units of penicillin intramuscularly, and boiled milk, but joint pain persisted and the cutaneous eruption gradually progressed He was first seen in consultation on the dermatologic service early in December, at which time a diagnosis of keratosis blenorrhagica was suggested and it was recommended that an investigation be made for a probable prostatic focus A genitourinary consultation disclosed no urethral discharge, shreds in the second specimen of a two glass test and a slightly boggy but not remarkably enlarged prostate, the secretion of which exhibited 50 white blood cells per high power field The patient consistently denied gonorrhea by name and symptoms He was given weekly prostatic massage and diathermy, and in January the urine was free of sediment and he had recovered from acute conjunctivitis of the left eye However, fever, tachycardia and joint pain persisted, with involvement of the right wrist and shoulder, onycholysis of all nails with hyperkeratosis of the bed and gradual extension of the skin eruption On Jan 11, 1947, the patient was seen in consultation by Dr Sulzberger, who suggested the possibility of an atypical psoriasis, the patient was transferred to the dermatologic service

The patient then received daily starch baths to macerate the heavy corneous lesions, followed by application of 50 per cent salicylic acid in petrolatum The fever, tachycardia and arthropathy continued unchanged, while a severe secondary anemia was now evident, the hemoglobin was 11 Gm, red blood cells 3,200,000, and white blood cells 8,200, with polymorphonuclear leukocytes 67, lymphocytes 25 and eosinophils 6 per cent Small transfusions of 250 cc of whole blood were administered with improvement

Biopsy revealed pronounced parakeratosis and acanthosis, migrating leukocytes in the rete processes and a heavy cellular infiltrate in the upper third of the corium The papillae were greatly elongated with thinning of the suprapapillary plates while the rete pegs were thickened, clubbed and fused These observations were felt to be consistent either with keratosis blenorrhagica or with psoriasis

The patient continued to show erosive lesions of the tongue and palate, but no vesicles were ever seen The original eruption on the genitalia had subsided, but on the lower extremities the lesions had tended to coalesce to form indurated, erythematous plaques in which the original papules could be distinguished The trunk, forearms, upper arms, nose and scalp were now involved by the process, and close study revealed that new lesions appeared first as apparent vesicles, perceptibly hard, which became pustular (cloudy) in about four days and then commenced to exhibit a tan, heaped-up, tenacious and hard crust The corneous exudate appeared to project through the skin, its base being surrounded by a slight erythematous halo Where formerly these hornlike excrescences had remained intact, they now yielded to the action of baths and salicylic acid and desquamated, leaving dime-sized, bright red papules These papules tended to coalesce to form the plaques previously described on the ankles

Prostatic secretion continued to show many pus cells Ointments of 10 per cent crude coal tar and 5 per cent ammoniated mercury had no effect, and the patient was then given bismuth sodium triglycollamate by mouth, beginning January 25, with 1 tablet (75 mg of bismuth) three times daily and increasing to 2 tablets (150 mg of bismuth) three times daily for a total equivalent of 9 7 Gm of bismuth No effect whatever was obtained On February 27 he was given potassium arsenite (Fowler's) solution by mouth, treatment commencing with 4 drops three times daily, gradually increasing to 7 drops three times daily and then decreasing to 4 drops again, for a total of 20 3 cc over a period of nineteen days Again no effect was evident

form staining of the entire section with hemosiderin rather than a spotted deposition of hemosiderin There was no evidence of any tumor stage, such as fibrosarcoma I believe that this is probably an early stage of Kaposi's sarcoma both clinically and histologically One must bear in mind that Kaposi's sarcoma can progress slowly, just as mycosis fungoides may remain in an early plaque stage simulating parapsoriasis for a period of many years

DR STEPHEN ROTHMAN The patient presented by Dr Senear was seen in the University of Chicago Clinics by Dr Stenhouse and myself in 1943 At that time the tentative clinical diagnosis of Majocchi's disease with hypertension was made The biopsy specimen did not show extravasation of blood or blood pigment I believe that the eruption has not changed much in the last four years, and it is remarkable that the hypertension, too, is rather benign and stationary

Gottron in Germany stressed the point that Majocchi's purpura is always associated with either polycythemia or hypertension I do not know whether this has ever been confirmed, but the association of a widespread telangiectatic eruption with hypertension certainly is remarkable

DR F E SENEAR Several years ago I observed 2 cases, 1 patient was shown before this society and originally presented the somewhat mammalated appearance that this patient showed on the leg Histologically the lesions in both cases were typical of Kaposi's sarcoma

DR HARRY R FOERSTER, Milwaukee In our case we had considered the possibilities of Kaposi's idiopathic hemorrhagic sarcoma, amyloid disease and lichenoid pigmentary dermatosis and, on clinical grounds, decided in favor of the last named Dr Montgomery made a histologic diagnosis of Kaposi's sarcoma without having seen the patient MacKee and Cipollaro reported a case of Kaposi's sarcoma in which only inflammatory manifestations were present, which is in accord with Dr Webster's comment I am inclined to agree with him Our patient observed his first lesions three years ago These lesions were confined to the feet, particularly the dorsa of the toes, for almost three years In January 1946, the eruption extended to the dorsum of each foot and to the ankles, and during the last five or six months lesions have appeared on the legs Today he shows lesions that have developed since our first examination of him six weeks ago These lesions are more of a purpuric type The dark red in this case contrasts with the orange in Dr Caro's case, which I thought was an example of Schamberg's disease In Schamberg's or Majocchi's disease I have not seen the papular infiltrate exhibited by our patient, nor have I seen a case of Kaposi's sarcoma with so little infiltration I therefore favored a diagnosis of pigmented purpuric lichenoid dermatitis

Extensive Morphea Presented by DR S ROTHMAN and (by invitation) DR L RUBIN

Eosinophilic Granuloma Progress with High Voltage Roentgen Therapy Presented (by invitation) by DR M PIERCE and DR S ROTHMAN

Since this patient was presented originally at the Chicago Dermatological Society, in February 1947, further search for a positive agent in cultures from biopsy specimens, inoculation into guinea pigs and on bacteriologic mediums have failed to reveal the presence of an organism

On February 28, a biopsy of the skull lesion in the right parietal bone was made The histologic picture of this lesion was similar to that found in the granulomatous lymph node tissue The microscopic report was as follows The

tissue fragments were made up for the most part of large acidophilic or nonfoamy macrophages These had large irregular-shaped nuclei with indistinct nucleoli They contained a moderate amount of cytoplasm Many of these macrophages were binucleated, and there was some infolding of the nuclear membrane Scattered among these cells were a moderate number of eosinophils, more numerous in some of the fragments There were also a few smaller cells with dark nuclei, which presumably were lymphocytes There were a few multinucleated giant cells, some of these containing vacuoles or slitlike spaces A stain for fat (sudan IV) revealed that a moderate number of the macrophages contained small or moderate-sized fat droplets, or lipoprotein granules, most of which were not anisotropic Blood lipid studies showed no elevation of the total blood lipids or blood cholesterols

Therapy consisted of external irradiation, massage and physical therapy to correct the fibrosis in the cervical region Before admission to Bobs Roberts Hospital, the child had received a total of 2,593 r between Jan 13, 1939 and June 12, 1945 Since June 14, she has received forty-three treatments to seventeen cutaneous lesions, totaling 1500 r with single doses of 300 to 500 r She has experienced no radiation sickness She improved progressively The lesions are gradually regressing, and at present there are no discharging areas She has gained 27 to 30 Kg in weight since admission The retraction of her head has improved to some degree The patient is now to be discharged from the hospital and will be followed in the outpatient department

Eosinophilic Granuloma Presented by DR EDWARD A OLIVER and (by invitation) DR E LORANT

M E C, a white man aged 42, was presented at the March meeting He is presented today to show the effect of treatment

DISCUSSION

DR H M BULEY, Champaign, Ill (by invitation) These 2 cases illustrate again that there are various etiologic entities in eosinophilic granuloma In both cases there is symptomatic involvement which would not be present in many other cases The improvement following roentgen ray treatment is remarkable In the case I observed roentgen rays had no effect I saw the patient two weeks ago, and the lesions were practically as I saw them two years ago

DR ASHTON L WELSH, Cincinnati (by invitation) I wish to report further on the patient that my co-workers and I observed in Cincinnati, who was treated in the same fashion as this one His improvement was as striking as was the improvement in Dr Oliver's patient He now has fewer lesions, has gained weight and is considerably improved His spleen, which was palpable before roentgen therapy was begun, is still palpable but decidedly smaller The few small palpable lymph nodes that he had before roentgen therapy are still palpable and have been only slightly reduced in size They were chiefly around the neck and in one axilla We have been carefully watching this man, and I cannot help feeling that this syndrome is a little different from other forms of lymphoblastoma, if it is a lymphoblastoma, particularly in that the toxic or "id" reactions in this syndrome are so pronounced Low voltage roentgen rays administered to various skin areas in the man we treated produced little change, as in Dr Oliver's case

DR HAMILTON MONTGOMERY, Rochester, Minn Eosinophilic granulomas of the skin should be differentiated from eosinophilic granulomas of the skin and bone A series of articles appeared in the February 1947 issue of THE ARCHIVES Eosinophilic granuloma of the skin may be of various types, including pseudo

At this point, Dr Lionel Rubin, consultant, suggested the use of estrogenic substance On April 3, diethylstilbestrol therapy was begun, he was given 0 5 mg daily, which was increased to 1 5 mg daily At the end of two weeks no new lesions were appearing and former lesions on the trunk were evident only as pigmented macules The mouth was clear Painful gynecomastia necessitated reduction of the dose of diethylstilbestrol to 1 0 mg daily on April 18 Improvement continued rapidly with respect to the cutaneous eruption, but no improvement of the arthritis was noticeable Roentgen reexamination on May 2 showed extensive demineralization of all osseous structures visualized, narrowing of involved joint spaces due to cartilaginous destruction and varying degrees of flexion and extension deformity Comparison of these roentgenograms with those of December 1946 revealed a fulminating type of rheumatoid arthritis

At present the patient exhibits loss of all finger nails, with hyperkeratosis of the nail bed, and an erythematous plaque on the dorsum of the right foot, which is slightly infiltrated The joint deformities persist in the fingers and toes, but the large joints are much less painful and motion is greater The patient has lost 70 pounds (32 Kg) during his illness Since April 17, the afternoon temperature has been less than 100 F

DISCUSSION

Dr E T Bernstein I think that the disease in this case is arthropathia psoriatica It seems to me that the nails and skin showed lesions of that disease

Dr Emory Ladany (by invitation) This case does not impress me as one of keratosis blenorrhagica for the following reasons In keratosis blenorrhagica there is gonorrhea This patient denies gonorrhea, and prostatic smear and cultures were negative It may be arthropathic psoriasis Since 1920, keratosis blenorrhagica has frequently been confused with arthropathic psoriasis In keratosis blenorrhagica, a urethral discharge precedes the arthritis, which is followed by the cutaneous lesions In arthropathic psoriasis there are first cutaneous lesions and then joint lesions In keratosis blenorrhagica the large joints are usually the ones involved and there is no distortion There may be a few cases with ankylosis of the involved joints, but this is rarely so Usually the arthritis is evanescent, whereas in arthropathic psoriasis the small joints are usually attacked and ankylosis and deformities are common The other diagnostic possibility is Reiter's disease, which has also been mixed up with keratosis blenorrhagica in the last decade or so This is a urethritis which is nonspecific, with arthritis and nonspecific conjunctivitis Ocular lesions are also common in keratosis blenorrhagica, and they have been reported exceptionally in arthropathic psoriasis Out of 47 cases of Reiter's disease reported, in only 13 were there cutaneous lesions, but without such great deformities of the nails and joints as in this case I reviewed 166 cases of keratosis blenorrhagica and also dealt with the differential diagnostic points of the two other diseases, and I believe that the disease in this case is arthropathic psoriasis

Capt C D Bell (by invitation) About a month ago this man's appearance was different than it is today At that time there was a generalized eruption, of which one now sees evidence in the form of pigmented macules on the trunk and upper extremities This was characterized as a vesiculopustule These lesions developed day after day, they started as vesicles, became pustular and then hyperkeratotic It is true that there is no gonorrhea On the other hand, the prostatic smear even today was loaded with pus cells, so that I think that there is fair evidence that at some time the patient did have a urinary disorder

and shoulders Vesicular encrusted lesions in plaques are seen in arciform arrangement with active borders and clearing center The old lesions seem to have left depigmented areas The Nikolsky sign can be elicited near the lesions

Results of serologic tests for syphilis were negative, the urine was normal, and no fungi could be found in scrapings The report of biopsy by Dr Charles Sims was Hailey-Hailey disease

The patient is married and has no children He does not know whether either of his parents or his brother or sister had a similar condition

DISCUSSION

DR ARTHUR B HYMAN It was suggested that this might be tertiary syphilis because of the configuration of the lesions, but they are crusted and bullous and there is a positive Nikolsky sign There is some clinical similarity to dermatitis herpetiformis, but the eruption does not itch The patient said that he has had it for six years The unusual feature is the fact that, if his story is correct, the eruption developed at the age of 67 No cases have been reported in which the disease developed as late as that Most cases are familial, but such a history was not elicited from this man His parents died years ago, and his siblings live far away, so that he would not know about the state of their skin Fortunately, the histologic picture in Hailey-Hailey disease is characteristic

DR GERALD F MACHACEK I treated a patient with a similar condition, and the patient improved with large doses of vitamin A, the improvement lasting over a period of months I do not know the ultimate outcome

As a matter of fact, the problem is older than when the Haileys posed it McCarty, in his "Histopathology of Skin Disease," wrote of these peculiar cases which have some characteristics of pemphigus and some of Darier's disease

DR WILBERT SACHS I was surprised to hear Dr Hyman call this Hailey-Hailey disease In our article my co-workers and I decided that this is a variant of epidermolysis bullosa

DR ARTHUR B HYMAN (by invitation) Whether it be epidermolysis bullosa or not, this eruption was described by Hailey and Hailey, and therefore there is no discrepancy

The lesions in Hailey-Hailey disease are found on the sides of the neck, axillas and groins with a degree of symmetry, and there is usually a familial history The disease lasts many years with frequent remissions One can generally exclude other possibilities, such as tinea by mycologic examination, syphilis and other diseases, by careful analysis of history, lesions and symptoms The histologic aspect of this disease is characteristic, and the only other eruption for which it could be mistaken at a quick glance under the microscope is Darier's disease, but in the latter one always finds corps ronds and grains In Hailey-Hailey's disease the lacunas are characteristic and are found just above the basal cell layer, corps rond are not found, and grains are rare

Sarcoid, with Results of Kveim Test Presented by DR JESSE A TOLMACH

E L, an Italian woman aged 39, is presented from the New York Skin and Cancer Unit with an eruption of six years' duration Nearly the entire scalp is involved with scaly erythematous flat patches Around the right ear and toward the back of the neck there are several pea-sized papules of light yellow-orange On the left side of the face, right arm and right thigh there are indurated telangiectatic coin-sized plaques The past history is not relevant

DR LIONEL C RUBIN (by invitation) This patient gives no history of gonorrhea, but, as Dr Bell stated, he has chronic prostatitis, before studies for bacteria were made he had already received 5,000,000 units of penicillin, so that may have prevented isolation of the Gonococcus In this case the joint changes preceded the cutaneous eruption by months In psoriasis it is the reverse Also, the cutaneous lesions were originally vesicles and pustules, becoming hyperkeratotic, of the waxy type, which is characteristic of keratosis blenorrhagica, and he had lesions in the mouth He has a history of iritis That would be difficult to fit in with psoriasis, but it would fit in well with gonorrhea He had a severe constitutional reaction, with pronounced loss of weight and a swinging temperature Why was there no response to penicillin? Such cases have been reported in the literature, and I think that Dr Ladany's patient had positive evidence of gonorrheal urethritis, yet the rash and joint pains did not respond to penicillin therapy There has been great improvement in the last two weeks I do not know whether that is coincidental or whether it was due to the diethylstilbestrol therapy Every type of therapy had previously been tried without improvement, and diethylstilbestrol was suggested because of the rarity of this condition in female subjects After the patient had received diethylstilbestrol, gynecomastia developed, he began to improve, and practically all the cutaneous lesions disappeared

DR LOUIS TULIPAN I believe that this is a case of psoriasis arthropathica In this disease hyperkeratotic lesions are prone to develop, especially on the palms and soles, plus pronounced subungual keratosis In gonorrheal arthritis one expects a monarticular involvement This man has a multiarticular involvement He has a generalized eruption on the body, which coincides with a superficial type of psoriasis, and shows fairly typical plaques I do not believe that arthropathic psoriasis can be ruled out simply because the arthritis preceded the eruption, or vice versa I feel that it is a case of psoriasis arthropathica

DR WILLIAM CURTH Was a complement fixation test for gonorrhea performed?

DR RUDOLPH L BAER Besides the complement fixation test for gonorrhea, it might be worth while to try a new procedure recently described, which might help to differentiate the present eruption from Reiter's disease In the Scandinavian literature (Storm-Mathisen, A *Acta dermat-venereol* **26** 547, 1946) is described a skin test for Reiter's disease using as test material tissue emulsions and joint exudate from a patient with "known" Reiter's disease

DR LOUIS TULIPAN I would also suggest that this man might have received medication for his arthritis—one of the sulfonamide drugs or some other drug—and that the vesicular-pustular eruption which developed all over the body may have been a reaction to that or to the penicillin Such eruptions frequently terminate in the guttate or nummular form of psoriasis

DR MARION B SULZBERGER The discussion shows that this is still a case for diagnosis I would put arthropathic psoriasis first with a question mark, keratosis blenorrhagica with two question marks second and Reiter's disease with three question marks third I have seen 3 cases almost identical to this one, and the same discussion followed in each instance One thing was not mentioned In the one biopsy, the histologic picture was characteristic of psoriasis The patient is beginning to improve since receiving diethylstilbestrol Dr Rubin is to be complimented Even though it is not yet certain that this estrogen has cured the patient, it would surely be well worth while to treat other patients with that preparation The similar case Dr Baer and I reported and depicted (Sulzberger, M B, and Baer, R L Yearbook of Dermatology and Syphilology, Chicago, The Year Book Publishers, Inc 1944, pp 202-203) terminated fatally

Results of serologic tests for syphilis were negative The urine and blood cell count were normal The tuberculin reaction was negative in a dilution of 1 100 A roentgenogram of the chest showed perhaps slight engorgement of the superior great vessels There was a slight degree of lymphoid nodulation at the hilus and root devoid of definite etiologic characteristics There was moderate generalized hypervascularity No evidence of recent parenchymatous infiltration was seen The report of biopsy was sarcoid The result of the Kveim test was negative after nine days, with the Oslo antigen With the Copenhagen antigen it appeared to be 1 plus after three days and 1 to 2 plus after seven days

DISCUSSION

DR DAVID BLOOM The patient shows typical sarcoid lesions on the back of the neck, but the other lesions are flat and not infiltrated Together with the lesions on the scalp, they form an extraordinary feature in this case

Sporotrichosis Presented by DR TIMOTHY J RIORDAN

H W, a white man aged 50, born in the United States, is presented from St Vincent's Hospital The patient worked for two months repacking novelities shipped from Mexico in what is called "Mexican hay" In reshipping, this "hay" is mixed with excelsior On Jan 7, 1947, a thorn of cactus pricked the right middle finger The patient said that when he pulled out the thorn at least half an inch (1 cm) had been embedded under the nail plate He applied iodine Three days later he complained of a red, painful swelling He was cared for by a surgeon, and after four days of wet dressings the infected area was incised and

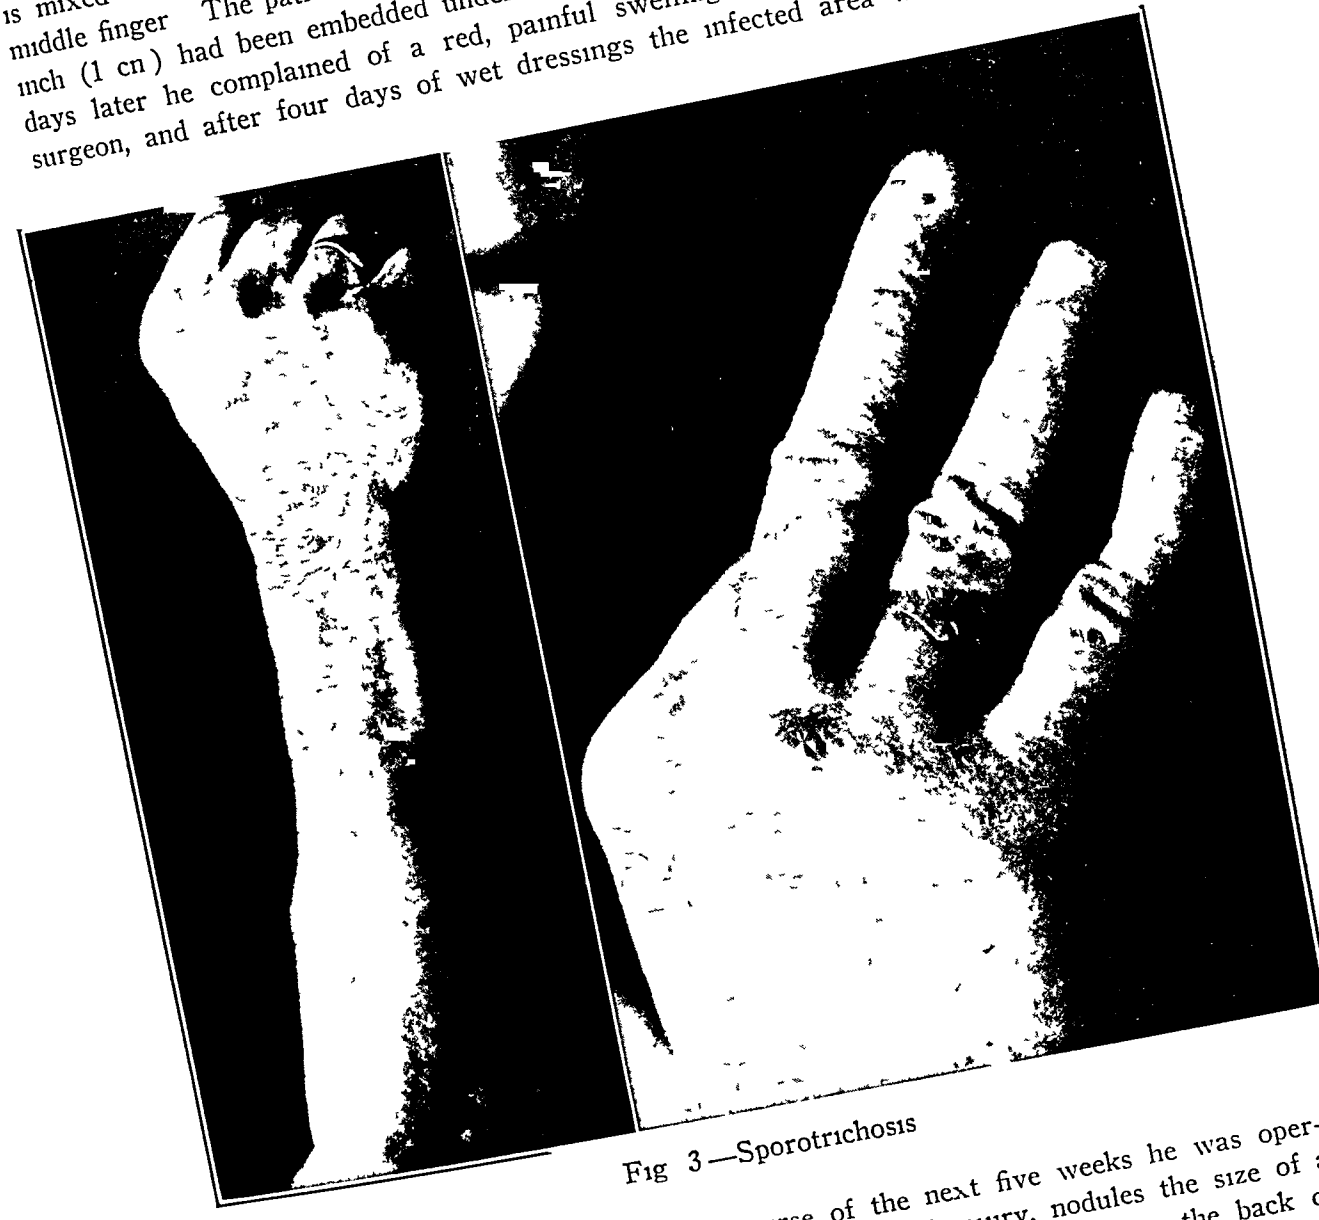

Fig 3—Sporotrichosis

the nail partially removed In the course of the next five weeks he was operated on four times Seven weeks after the date of injury, nodules the size of a pea and larger appeared, extending from the distal phalanx across the back of the hand and forearm to above the elbow These nodules were in linear arrangement, apparently following the course of the lymphatics They were dusky and firm, and subsequently one or two broke down Microscopic examination of the material discharged failed to reveal evidence of fungi Cultures from the nodules were positive, corroborating the diagnosis It is important to note that there was no enlargement of the epitrochlear or axillary lymph nodes Prior to the spread of the infection penicillin therapy was used without effect

NEW YORK DERMATOLOGICAL SOCIETY

George C Andrews, M D, *President*

George M Lewis, M D, *Secretary*

March 26, 1946

Axillary Hidradenitis Suppurativa, Pyoderma, Cystic Acne in a Girl Aged 15 Presented by Dr Fred Wise

Nevus Cerebriformis Presented by Dr Fred Wise

B G, a single girl aged 18, in good general health, presented a birthmark involving the skin of the posterior and external lateral surfaces of the right thigh It extended from the gluteal fold down to about one third the length of the thigh, it was roughly rounded in outline, with well defined borders and was approximately 8 inches (20 cm) in diameter In addition to the primary growth, there were a few scattered satellite, pea-sized nodules at a distance from the main lesion The tumor consisted of groups of soft, light brown, partly pedunculated and partly sessile nodules, some of which exhibited cerebriform and cauliflower-like surfaces, while others consisted of yellowish white, rounded, easily compressible "lumps" resembling superficial deposits of fatty tissue, covered with clinically normal skin

The birthmark produced a pronounced degree of disfigurement of the affected region, the patient was presented for the purpose of obtaining advise as to therapy

DISCUSSION

Dr. Howard Fox I would do nothing at all for this lesion It is fortunate that it is not situated on the face, neck or arms To perform an extensive skin graft would be ridiculous, as the lesion does not bother the patient in the slightest degree

Dr. Eugene F Traub The lesion in this case is too extensive in my opinion for surgical intervention Furthermore, since the lesion is a spreading and extending one, I feel sure that it would certainly promptly appear beyond the line of surgical excision This in itself would be most distressing to the patient and would, in my opinion, argue against surgical removal Superficial desiccation, on the other hand, could be carried out on each of the lesions, and, because of the large amount of intervening skin between the patches, this would strike me as being the treatment of choice Microscopic examination of one of the lesions would prove that this is probably a benign type of growth, and, if the desiccation is carried out properly, it could be done with safety and great improvement to the patient

Dr A Benson Cannon I agree with Dr Fox This lesion should be untreated, but, should treatment be demanded, it might be possible to remove the lesion in successive steps, leaving only a linear scar eventually

Dr. George M MacKee I suggest leaving the lesion alone, or else complete excision, with plastic repair I know of several instances in which epithelioma developed in this variety of nevus after it had been severely traumatized with solid carbon dioxide

The patient was given sodium iodide, 1 Gm daily the first week and every other day thereafter, with potassium iodide by mouth He has responded well, and eruption is almost clear, but there is still evidence of nail changes and residual nodules are present on the forearm

This is the first compensation case of sporotrichosis in the state of New York

NOTE —One year later the patient was completely cured

George M Lewis, M D, *Chairman*

Marion B Sulzberger, M D, Secretary

Nov 5, 1947

Follicular Lymphoblastoma Presented by DR FRANCES PASCHER

H R, a man aged 44, complains of lymphadenopathy of three years' duration A node was excised for histologic examination from the right axillary chain two years ago There has been no palpable change in the size or consistency of the nodes during the three months in which the patient has been under observation A red patch appeared near the left temple one year ago A few weeks later a similar lesion appeared near the right temple The patient has lost about 10 pounds (4 5 Kg) during the past three years He has been well enough to work but does not feel as energetic as formerly

There is a well defined plaque of erythema and infiltration in both preauricular areas The nodes in all superficial chains are enlarged The liver and spleen are not palpable

A biopsy specimen was taken from the right temple on August 8 The section showed masses of cells not surrounded by any inflammatory exudate The collagen fibers within the lesion were edematous and broken The cellular exudate consisted of small round cells containing highly pigmented nucleoli There were no eosinophils or mitotic multinucleated cells The diagnosis was lymphoblastoma

The section taken from the lymph node was examined by Dr M Richter, and the diagnosis was malignant lymphoma, follicular type

A roentgenogram of the chest revealed no abnormalities Scout roentgenograms of the abdomen showed a slightly prominent liver and spleen Study of the sternal marrow was attempted, but a suitable specimen could not be obtained Three complete blood counts were normal, as were the results of urinalysis The Wassermann reaction of the blood was negative

DISCUSSION

DR DAVID BLOOM Years ago I saw all the patients for whom this diagnosis was made at Bellevue Hospital All the patients showed universal erythroderma with pronounced enlargement of the lymph nodes This patient shows only a few circumscribed cutaneous lesions in association with generalized adenopathy The diagnosis as presented should therefore be questioned

DR GERALD F MACHACEK I have seen several patients without erythroderma and without glandular involvement—1 with the lesions localized, 1 more diffuse and both of them evidently cured by total excision Reexcision was necessary for 1 a year after the first operation, but ultimately the entire disease process was eliminated and the patient cured

DR MAURICE J COSTELLO I should like to confirm what Dr Bloom said, that all patients observed during the time Dr Symmers was making his studies of this disease had generalized or universal erythroderma I cannot recall a case in which the eruption was limited to a small area I think that the patient must have

Universal Scaling Erythroderma Presented by DR HOWARD FOX

Lichen Sclerosis et Atrophicus, Accompanied with a Bullous Eruption Involving Vitiliginous Areas of the Vulva and Anus Presented by DR MAURICE J COSTELLO

Dermatitis Herpetiformis Refractory to Treatment with Sulfonamide Drugs Presented by DR MAURICE J COSTELLO

Nevus Pigmentosus et Pilosus Presented by DR ANTHONY C CIPOLLARO

D W, aged 2 months, was first seen on March 21, 1946, because of an extensive nevus involving the major portion of the body The father and mother have no similar lesions, and there is one other child in the family, who is well The pediatrician informed the parents of the possibility of cancer developing in these lesions and of the possibility that the child may grow up with mental defects

The patient now presents a lesion which is black and thick, and involves the bathing trunk area and halfway up the trunk There is hair in all parts of the lesion On other portions of the body are isolated black or brown pigmented hairy lesions

DISCUSSION

DR HOWARD FOX This case of bathing trunk nevus is not the typical brown hairy type The pigment is rather dark, almost black, and, in addition, there are other defects There is nothing that can be done for this child

DR A BENSON CANNON I believe that this is a benign type of lesion

DR EUGENE F TRAUB There are two types of nevi present in this case One, an ordinary brownish black, pigmented lesion with some slight fine downy hair, and the other, a deeper-seated bluish black or slate black mass It is possible, therefore, that there are a blue nevus and an associate nevus of another type, possibly a junction To further complicate the picture, there are some nodular masses underlying several of the bluish lesions, and they may be part of the bluish nevus, or they may perhaps represent areas of subcutaneous fat necrosis of the newborn The child is just a few months old, and the masses have been present since directly after birth As subcutaneous fat necrosis of the newborn is a self-limited process and usually clears up in a month or two, keeping this patient under observation will settle the diagnosis without the need of a biopsy

DR FRED WISE Is it the consensus of the members that the nevus be untreated?

DR HOWARD FOX None of the patients with subcutaneous fat necrosis that I have studied had pigmentation like this, and there always was a definite hardness which this child does not have In subcutaneous fat necrosis of the newborn, the skin is practically normal in color The location of the disease is also different from that in this patient

DR MAURICE J COSTELLO I think that the masses represent the fibrolipomas rather frequently observed in this type of pigmented hairy nevus I agree with Dr Fox that there is nothing in these tumors to suggest subcutaneous fat

enlargement of the mediastinal nodes, because dilatation of the superficial cutaneous veins was a prominent feature, producing a caput medusae effect

DR WILBERT SACHS The patients that I have seen had not only generalized erythroderma but also severe itching Any such extensive eruption associated with prolonged itching may give a similar picture Some believe that the constant scratching results in the enlarged lymph nodes and that Symmers' disease is not an entity per se

DR EUGENE F TRAUB I am not sure whether the history stated whether the other lymphoblastomas, such as leukemia and mycosis fungoides, had been excluded, as the nodules in this case seem unusually firm I, too, have had the experience of seeing only generalized erythroderma in patients with this microscopic picture and have followed 1 case for approximately fifteen years, during which the patient had about three severe exacerbations and then the disease cleared up as a result of local therapy only It seemed to me that in these cases the lymph node involvement was secondary to that of the skin, but that does not seem to be the case in this patient, in whom the lymph nodes enlarged before the cutaneous lesions appeared Perhaps the presenter can tell us what has been done to exclude the other types of lymphoblastomas

DR ELSE A BARTHEL The condition in the biopsy specimen of the skin definitely resembled leukemia rather than a lymphoblastoma The appearance of the biopsy specimen of the lymph node was that of a lymphoblastoma Since the node reactions offer more of a diagnostic picture than the skin, it was thought preferable to accept the diagnosis based on the pathologic changes in the lymph node

DR FRANCES PASCHER The concept of giant follicular lymphadenopathy, or Brill-Symmers' disease, is still in an evolutionary phase It is now regarded by Craver and others at Memorial Hospital as "an early setting for lymphosarcoma" rather than a disease entity In 1938 Symmers pointed out that in some cases of universal chronic erythroderma there is local or general enlargement of the superficial lymph nodes with the histologic characteristic of giant follicular lymphadenopathy Similar histologic changes in the lymph nodes have also been described in association with other dermatoses Hurwitt *(J Invest Dermat, 1942)* stated that the benign follicular hyperplasia in the lymph nodes associated with dermatoses differs definitely from that in follicular lymphoblastoma He designated this benign follicular hyperplasia as dermatopathic lymphadenitis Differential diagnoses can be made only after careful study

My impression is that the patient presented has a follicular lymphoblastoma which has developed into a lymphosarcoma with cutaneous metastases The mediastinal nodes are not enlarged, and the blood cell count is normal

(NOTE—A lymph node was later excised, and the histologic report was lymphosarcoma)

Postvaccinal Erythema Multiforme Bullosum? Epidermolysis Bullosa? Presented by DR JOSEPH L MORSE

Multiple Superficial Basal Cell Epitheliomas Presented by DR JOSEPH L MORSE

M H, a woman aged 65, is presented from the Skin and Cancer Unit with a history of having taken potassium arsenite solution (Fowler's solution) at intervals for many years for the treatment of "eczema" The lesions first developed about thirty-five years ago, and since then new ones have continued to appear Many were treated years ago at the Vanderbilt Clinic with roentgen rays and radium

necrosis of the newborn The duration and age of the patient is against it A malignant melanoma may develop in this infant

DR ANTHONY C CIPOLLARO I do not believe that there is any fatty necrosis here I do not believe that this shows any lipomatous tissue I think that it is a mass of nevus cells I feel, as do most of us here, that the lesion should not be treated and that nothing can be done for the child, I agree with Dr Cannon that it is a relatively benign type of lesion

Mycosis Fungoides. Presented by DR FRED WISE

Chronic Lichenoid Discoid Dermatitis, Arrested; Dermatophytosis, Erythroplasia Presented by DR A BENSON CANNON

Universal Scaling Erythroderma Presented by DR HOWARD FOX

L S, a man aged 62, a dress shop owner, first noticed an eruption ten years ago It began on his legs and within six years had become universal The eruption is red, scaly, dry and nonpruritic In each axilla there are two partly fused, firm lymph nodes, the size of a pigeon's egg and a hen's egg, respectively

Laboratory examinations showed a faint trace of albumin in the urine The Kline and Mazzini reactions of the blood were negative A blood examination on Nov 10, 1944, showed 6,500 leukocytes, with 52 per cent polymorphonuclear neutrophils, 44 per cent lymphocytes and 2 per cent eosinophils A second blood examination, on March 7, 1946, showed essentially normal observations, except for 12 per cent monocytes

A biopsy specimen taken on Feb 1, 1946, was examined by Dr Wilbert Sachs, who made a microscopic diagnosis of tuberculosis cutis His report was as follows Throughout the middle and upper parts of the cutis there is a diffuse intense cellular infiltration composed of wandering connective tissue cells, small round cells, occasional plasma cells and many epithelial giant cells, the latter arranged in tubercle formation The overlying epidermis is irregularly acanthotic Part of the basal cell margin is washed out and part is intact There is some parakeratosis No lepra organisms were found

Four years ago, and again one year ago, the patient was operated on for inguinal hernia, on each occasion by a different surgeon Both operations were failures and were followed by large elephantiasic masses in the upper third of the thighs On one of these occasions, an inguinal (or femoral?) node was excised and examined microscopically It was said to have shown nonspecific adenitis

The patient appeared to be in fairly good general health He never takes drugs, including vitamins He has had a good deal of roentgen treatment without any benefit, which would tend to exclude either psoriasis or mycosis fungoides

DISCUSSION

DR FRED WISE Generalized tuberculous erythroderma was described by Jadassohn (Volk, R Tuberkulose der Haut, in Jadassohn, I Handbuch der Haut- und Geschlechtskrankheiten, Berlin, Julius Springer, 1927 vol 10, pt 1, p 420)

The patient now has several discrete crusted lesions on the forehead, sides of the cheeks, back and abdomen and small superficial erythematous macules scattered on the trunk and extremities There are several whitish atrophic scars and telangiectatic atrophic areas on the forehead, cheeks, abdomen and thighs Numerous keratoses are present on the back and abdomen The palms and soles are free of lesions

A report of biopsy of a lesion on the abdomen was basal cell epithelioma

Multiple Superficial Basal Cell Epitheliomas with Arsenical Keratoses

Presented by Dr Jack Wolf

C B, a man aged 60, was previously presented before the Manhattan Dermatological Society on Oct 14, 1947, with multiple lesions on the trunk and legs of about twenty years' duration

DISCUSSION

Dr Eugene F Traub This type of case is not uncommon, and one sees some who have taken arsenic and others who have not A relationship to psoriasis has also been observed, or, at least, patients have been seen in whom the multiple epitheliomas were perhaps mistaken for psoriasis, in others, psoriasis had been treated with arsenic and later multiple superficial epitheliomas developed In 1 case, the multiple epitheliomas had been mistaken for tinea and in a laboratory fungi were found in each of the lesions This in itself should have made any observer suspicious, because fungi are not found so readily in every lesion It is not known exactly how arsenic influences or brings about these lesions or just what the effect of sunlight may be A great deal has been said about treatment, and it has been said that the lesions are sometimes more difficult to cure than the ordinary basal cell lesion on the face This has not been my experience, as improvement occurs with desiccation and curettement, either with or without roentgen therapy, and sometimes a sufficiently large dose of roentgen rays clears up the early lesions also

Dr Joseph L Morse What is the consensus as to treatment?

Dr J Gardner Hopkins I believe that roentgen rays are effective in this type of basal cell epithelioma Atrophy does occur in the area, but it is not a particularly threatening type In desiccating lesions on the trunk one is apt to see secondary infections My inclination would be to treat these lesions with roentgen rays first and then use desiccation for recalcitrant areas

Dr Wilbert Sachs The patient has different types of lesions seborrheic dermatitis, lesions similar to Bowen's disease, superficial basal cell epitheliomas and arsenical keratoses on the palms The lesions on the lower extremities are basal cell epitheliomas, corroborated by the microscopic observations The quantity of radiation necessary to destroy lesions which have been present for twenty to thirty years is large, and such therapy is rather radical However, such lesions occasionally do become active and heroic methods are needed

Dr David Bloom I have had occasion to observe patients with psoriasis who took organic arsenic and had arsenical keratoses on the palms and soles and, in addition, basal cell epitheliomas on the trunk and squamous cell epitheliomas on the extremities I believe that in this case there is a causal relationship between the ingestion of arsenic and the development of epitheliomas

Dr Charles Wolf These cases illustrate the fact that disseminated epitheliomas are always caused by drugs or actinic exposure Fortunately, in these cases the history is straightforward One does encounter cases in which the patient denies taking arsenic, but it must be remembered that it may be ingested in an occult way, as through the food or occupation As to therapy, I feel that where there are so many lesions on the body it is inadvisable to give radium or roentgen

DR GERALD F MACHACEK In the sections one finds microscopic evidence of the formation of tubercles I am, however, not certain that from this evidence alone one should accept the diagnosis of tuberculosis cutis Not so long ago I saw a similar case, that of a young person suffering from exfoliative dermatitis for many years Microscopic examination of sections from his skin showed not dissimilar tuberculoid infiltrations, but I was able to show to my own satisfaction that they were foreign body reactions to epidermal inclusions Others have reported and I have seen "tubercles" in cutaneous lesions of leukemia

DR HOWARD FOX I may say that the patient has no evidence of tuberculosis as far as I can find out He is perfectly well and has no itching, the only peculiar fact is the surgical reaction which he had on two successive occasions after herniorraphy

Squamous Cell Epithelioma, Grade 3 Presented by DR JOHN C GRAHAM

Juvenile Acanthosis Nigricans Presented by DR FRED WISE

Vitiligo with an Elevated Border Presented by DR FRED WISE

A L, a boy aged 13, registered at the Skin and Cancer Unit on Feb 26, 1946, presenting depigmented patches of two months' duration A vitiliginous spot first appeared on the penis, about one to two weeks later a spot appeared on the forehead, two weeks later on the left eyebrow and a month later on the left side of the forehead at the hair margin

The patient presents depigmented white patches on the forehead, left side of the neck, left eyebrow, shoulder and penis They vary in size from 1 to 3 cm The depigmented spot on the left side of the forehead is round, of silver dollar size and encircled by an evenly, slightly raised, threadlike border In the middle of the forehead is a blackish, depigmented, half-dollar-sized, round spot, which has been present since birth, surrounded by a depigmented zone of 0 5 cm The results of the routine laboratory tests were normal

From a section taken from the depigmented patch with the raised border Dr Charles F Sims made the diagnosis of superficial exudative inflammatory process The description follows The epidermis is slightly irregular Its surface is covered in part by a very mild, loosely laminated horny layer At several points the granular layer has all but disappeared The basal margin is pigmented throughout one portion of the section and relatively nonpigmented in the remaining portion There are scattered chromatophores The rete pegs are somewhat irregular, and at some points of the basal layer liquefaction has taken place At the latter point there is a mild cellular reaction composed for the most part of small round cells The vessels of the upper part of the corium are moderately dilated and surrounded by a sparse cellular reaction composed for the most part of small round cells Numerous vacuoles apparently due to edema are present at several points in the corium

DISCUSSION

DR EUGENE F TRAUB A similar case was presented at the American Dermatologic Association, Inc, meeting in Chicago about two years ago I do not recall exactly how the peculiar border was explained, except that there may be some inflammatory process at work and with the peripheral extension of this inflammatory and slightly elevated border an area of depigmentation is

treatment for fear of sequelae which are irreversible, especially in the later decades of life Bone marrow activity is at a low ebb, and, therefore, administration of actinic rays is fraught with greater danger than when they are given to a younger skin I would therefore advise local excision as the better and safer procedure with so many lesions

DR JOSEPH L MORSE We all realize that arsenic has some relation to the production of basal cell epithelioma It is interesting that 2 such patients should be encountered at one meeting, one showing arsenical keratoses and the other not, but both with a history of ingestion of potassium arsenite solution, and it seems more than a coincidence that in both patients epitheliomas should have developed I have treated some of these lesions, and I think that they can be easily destroyed by electrodesiccation and curettage, certainly with better cosmetic results than this woman shows, and at the same time with no chance of radiation sequelae

Allergic Eczematous Cross Sensitization to Paraphenylendiamine and Several Azo-Dyes Certified for Use in Foods, Drugs and Cosmetics (Contamination of an Innocent Cosmetic with Paraphenylendiamine.)

Presented by DR RUDOLF L BAER and DR MORRIS LEIDER

S B, a woman aged 38, a worker in leather sundries, presented an eczematous eruption on the hands, arms, back and chest of eight months' duration Initial patch tests with a series of common eczematogenic allergens revealed a strongly positive (3 plus) reaction to paraphenylendiamine With this lead, additional tests were done, with the results noted in table 1

At this presentation the patient exhibits the results of patch tests applied forty-eight hours ago (table 2)

DISCUSSION

DR BEATRICE M KESTEN There is a crisscross sensitivity to adhesive tape I am not impressed by the cutaneous reaction to a test to nylon This woman wears nylon stockings, and she has no dermatitis on the legs I wonder whether she is so cross sensitive The results of patch tests as seen tonight do not exhibit it Perhaps she is sensitive to some of the ingredients in adhesive tape, and it might be well to test that possibility Instead of incriminating the numerous substances of which Dr Baer speaks, it might be that the patient is sensitive to paraphenylendiamine, a substance with which she comes in contact and to which she gives a positive reaction in patch tests

DR MARION B SULZBERGER If it can be shown that there are cases of cross sensitization between ordinary certified food dyes and other dyes commonly encountered in objects which come in contact with the skin from without, this might have a most important bearing on the difficulty of clearing up certain eczematous dermatoses when one has removed the offending external dye allergens Such refractoriness could perhaps be caused by relatives of the dyes being encountered in foods Moreover, it is possible that some eczematous or fixed eruptions which were reported as due to foods were really due to the dyes in these foods Because of the far reaching importance of these observations, I would again ask the presenter whether he considers the patch test reactions, as seen tonight, significant? I am inclined to agree with Dr Kesten that the patient tonight does not show any unequivocal reactions to nylon-dyes or other dyes

DR RUDOLF L BAER I agree with Dr Kesten and Dr Sulzberger that the test results in this patient are poor examples for demonstration I observed that several such "certified" azo dyes produced more strongly positive reactions in a

left Incidentally, this boy had a pigmented hairy nevus on the forehead, near the hair margin One of the patches of depigmentation involves this nevus, which is rapidly losing its pigment as a result.

DR A BENSON CANNON This is totally unlike any vitiligo that I have ever seen The linear rim around the white area is raised, red and firm, and the depigmented center is most likely the result of previous inflammation I think that we shall have to depend on the histologic examination for the diagnosis The raised lichenoid margin somewhat resembles lichen planus

DR FRED WISE It is interesting to call attention to the fact that a similar case was reported by Becker and Obermeyer (ARCH DERMAT & SYPH **36** 216 [July] 1937, and **37** 99 [Jan] 1938) Today the border is less elevated than when it was seen in the clinic, about two weeks ago Another interesting fact is that the patient has typical vitiligo of the penis and scattered vitiligo on other parts of the body, there are no signs of lichen planus and no signs of a border on the other lesions

A Case for Diagnosis (Poikiloderma? Localized Scleroderma?) Presented for DR GEORGE C ANDREWS by DR A BENSON CANNON

Neurodermatitis with Cataract and Asthma *Presented by* DR FRED WISE

F S, a young man aged 17, registered at the Skin and Cancer Unit on March 19, 1946, presenting lesions since infancy He has also been suffering with asthma since then The asthmatic attacks have been mild for the past several years The cataract in the left eye formed about three years ago He has five brothers and sisters who are well A cousin of his mother has asthma and had eczema The patient had chickenpox, German measles, scarlet fever, whooping cough and pneumonia in childhood and appendicitis at the age of 13 His general health has been good He complains of itching

The patient presents an almost perfectly symmetric and extensive eruption on the lower half of the forehead, face, front of the neck and upper and lower extremities On the face the lesions are distributed on the lower half of the cheeks, with the chin comparatively free On the upper extremities they commence just above the elbows, envelop the arms and end on the volar surfaces at the wrists, but include the dorsal surfaces, the hands and the terminal phalanx of the right middle finger The lesions are most pronounced on the lower extremities and encircle almost completely and uninterruptedly, except for the inner and upper surfaces of the thighs, the thighs and legs down to the distal half of the dorsal surfaces of the feet, terminating in a sharp margin They consist of heavily crusted oozing vesicular fissured patches, infiltrated and thickened to several millimeters The soles are hyperkeratotic, particularly the heels and the anterior metatarsal arches The back is uninvolved except for isolated spots On the chest, elbows and arms are fairly numerous pinpoint-sized to pinhead-sized, irregular, dry crusted patches on the back of the scalp In the groins the lymph nodes are enlarged to the size of goose eggs and in the axillas to cherry size

NOTE —The patient is hospitalized at the New York Post-Graduate Hospital Laboratory reports will be given later

DISCUSSION

DR GEORGE M MACKEE It is important, for medicolegal reasons, to know that spontaneous cataracts occur in this disease, otherwise roentgen treatment is likely to be unjustly blamed, as has not infrequently happened

number of patients with paraphenylendiamine hypersensitivity than in a series of "normal" control subjects Some of these dyes have primary irritant properties on human skin

There are many azo dyes that are certified by the Food and Drug Administration for use in food, drugs and cosmetics and others which are certified for use only in drugs and cosmetics Those azo dyes which were tested in this patient are certified for all three uses Their use is widespread, they can be encountered in such diverse products as nail polish, sausage casings, raspberry syrup and other beverages

We do not know yet what is the clinical importance of these reactions It is possible that these cross sensitizations to azo dyes may account for some of the chronicity in cases of dermatitis due to paraphenylendiamine, and perhaps also for

TABLE 1 —*Results of Tests*

Test Substance	Reading	Source of Contact

* Food drug and cosmetic dyes

some of the unexplainable flare-ups This particular patient showed a very mild reaction to tests with the dyed nylon stockings In most cases of paraphenylendiamine hypersensitivity, reactions to nylon stockings containing these azo dyes are much stronger However, the fact that the patient gives a positive reaction in a patch test but does not have a stocking dermatitis is not surprising, because even in cases of dermatitis due to dyes in nylon stockings, with strongly positive reactions, the entire leg is usually not involved In most cases only the dorsa of the feet and the popliteal spaces are involved, showing that the eruption tends to develop in sites where maximal extraction is likely to occur

As far as the deodorant cream is concerned, it is possible that the patient contaminated it with the nail polish, which may contain one of the azo dyes

DR EUGENE F TRAUB Why was the deodorant considered to be contaminated by nail polish rather than by paraphenylendiamine?

DR MAURICE J COSTELLO I had a patient who had received a great deal of roentgen rays (from another physician) to the face, and even though the eyes were covered with lead protectors bilateral cataracts developed The ophthalmologist attributed the cataracts to the roentgen ray therapy until he was informed of the association of juvenile cataracts with neurodermatitis He had never heard of spontaneous cataracts forming in young persons with the dermatosis and had always thought that they were caused by roentgen rays This is of medicolegal importance

George M Lewis, M D, *Secretary*
April 23, 1946

Sycosis Vulgaris Presented by DR HOWARD FOX

C V W, aged 38, a guard by occupation, was discharged from the Army five years ago, after three years of service During the last fourteen months in the Army he was constantly receiving treatment in various hospitals He now presents an eruption confined to the upper lip and entire bearded area, which was previously of pustular type and now resembles a scaling eczema

Treatment in Army hospitals consisted chiefly of penicillin, roentgen rays and ultraviolet irradiation He received an enormous amount of penicillin, administered both by intramuscular injections and as an ointment He received a total of three hundred and fifty injections, in three courses of treatment, which completely failed to influence the eruption He also had seven fractional doses of roentgen rays (without causing epilation) at the Walter Reed Hospital, after which he was practically well for two months The disease then recurred in the same severe form He was at one time given general and local ultraviolet radiation for six weeks, which was followed by a deep tan on the body, but had no effect on the eruption On another occasion, he used quinolor® ointment (contains 10 per cent benzoyl peroxide and 0 5 per cent quinolor® [a mixture of three chlorine derivatives of 8-hydroxyquinoline] in a base of equal parts of petrolatum and wool fat) in various strengths for two weeks with slight benefit The patient appears to be in good general health and is again working full time He was first seen by me on April 1, 1946, and since then he has used quinolor® ointment once a day with slight improvement

DISCUSSION

DR ANTHONY C CIPOLLARO Cases of sycosis vulgaris tax the resourcefulness of the dermatologist I find that manual epilation of infected hairs is effective Tyrothricin, penicillin and other new antiseptics in easily absorbable bases, combined with injections of toxoid and small weekly doses of roentgen rays improve or keep under control most cases of sycosis vulgaris I certainly oppose the use of roentgen rays for the purpose of producing permanent epilation

DR PAUL E BECHET I believe that the local use of penicillin in sycosis vulgaris should be discontinued if no improvement occurs after it has been applied for a week, as cutaneous reactions from penicillin are, in my experience, greatly increasing in number—so much so as to become almost commonplace I have

DR RUDOLF L BAER It is possible that some of the occupational materials had contaminated the old jar of deodorant cream However, it is conceivable that certified azo dyes contained in the nail polish might have been responsible

Lupus Vulgaris (Treated with Calciferol). Presented by DR MARION B SULZBERGER

A S, a woman aged 33, was previously presented at the New York Dermatological Society, on Oct 24, 1939 She is shown tonight to illustrate the good results of calciferol (crystalline vitamin D_2) therapy and the simpler dosage schedule employed

In 1924 the patient first noted an eruption on the right cheek consisting of small erythematous and tumid nodules which healed with central whitish depressed scars The eruption gradually spread to involve the entire right cheek, chin, nose, forehead and both lips Previous treatment included radium, roentgen rays, electrodesiccation, tuberculin, Kromayer lamp, generalized ultraviolet irradiation and gold sodium thiosulfate, given by various dermatologists and clinics, with no great improvement

On May 3, 1946, vitamins A and D_2 (100,000 units of each daily) were given, in addition to tuberculin and ultraviolet irradiation On October 4, all other treatment was discontinued and the patient was given ertron® (concentrated vitamin D preparation) capsules daily (50,000 units) plus calcium lactate (4 0 Gm daily) Since that time she has shown gradual, consistent and finally great improvement No new nodules have appeared, and there has been no peripheral spread The skin has become less erythematous and has assumed a more normal color In addition, it has been more flexible, and the patient stated that there is increased mobility of the circumoral tissues especially, which previously interfered with mastication and speaking

Lupus Vulgaris, Improved with Calciferol Therapy Presented by DR JACK WOLF

V T, a man aged 47, is presented from the New York Skin and Cancer Unit with an eruption in the left postauricular region of approximately fifteen years' duration He was born in Italy and has lived in the United States for the past twenty years The eruption has never been troublesome, and the patient presented himself only recently because of the gradual extension of the process

He presents an erythematous, well marginated, brownish red patch involving the posterior auricular region and extending on to the temporal and mastoid regions The lobe of the ear is involved, and well developed small nodules are present in this location The process has improved greatly since calciferol therapy was instituted about four weeks ago, the nodular lesions have regressed considerably

The Wassermann reaction of the blood was negative, and the urine revealed no abnormalities There was no reaction to the intradermal tests with tuberculin in dilutions of 1 100,000 and 1 10,000

A histologic report by Dr A Hyman stated that in the upper part of the cutis there were groups of epithelioid and giant cells in tubercle arrangement There was a banal infiltrate around the tubercles

DISCUSSION

DR MAURICE J COSTELLO Calciferol is a good medicament for lupus vulgaris I have also treated patients with generalized lichenoid sarcoid with calciferol with equally good results and think that it is worth a trial in this dermatosis also

observed two types of reaction caused by penicillin in sycosis, some patients showing a great increase in pustules and inflammation after its local use for a few days and others an acute vesicular outbreak with much redness and discomfort within forty-eight hours after its first application

I have used quinolor® in sycosis plus roentgenotherapy, 75 r once a week, with such satisfactory results that this method is used by me almost exclusively

DR MAURICE J COSTELLO I think that the best treatment for these cases is compound quinolor® ointment, and, if properly rubbed in three times daily, before and after shaving and at night, it is effective

DR JOHN C GRAHAM I have had poor results with penicillin in the treatment of sycosis vulgaris I have had better results with compound quinolor® ointment, but have had few permanent cures

DR FRED WISE I share the views of those who favor manual epilation, it is one of the most important methods of therapy The patient should be taught not to pull the skin out with the hair and to allow his beard to grow for two or three days I feel that some of these cases are almost incurable A fluid preparation known as intraderm® (antifungal agent) combined with tyrothricin is of considerable value in the treatment of this disease

DR EUGENE F TRAUB This patient has had much treatment, but the best remedy for so severe a condition has not as yet been used, and I see no reason why a careful roentgen epilation should not be done It has been my practice to do this in the bearded area, using a divided dose and alternating with ultraviolet rays from a cold quartz lamp to control and prevent a pustular flare-up This has always been successful, and the patient is free of eruption in approximately six weeks from the date of the first treatment I believe that the aftercare from this point on is also extremely important because there is a tendency to relapse Therefore, while the new hair is growing back, I usually have the patient use either quinolor® ointment, ammoniated mercury or some other similar mildly antiseptic cream If the new hair is kept free of infection, the patient is permanently cured

DR A BENSON CANNON Any case of folliculitis is difficult to cure While manual epilation is the method of choice in treating localized areas, in cases with generalized sycosis, it is almost impossible and certainly impractical to pull out all the hairs About a year ago I presented a patient with generalized sycosis of several years' duration who was cured with wet dressings and injections of penicillin and frequent potassium permanganate baths I had 3 cases of generalized sycosis cured with this treatment within three to six months

DR GEORGE M LEWIS In order to obtain maximum results from penicillin applied locally, some individualization in the strength of the application is desirable Cormia has found tests of sensitivity to the bacteria found in culture to be helpful in gaging the concentration of the penicillin to be used Empirically, one may use higher percentages of penicillin when the response is poor to standard strengths

DR GEORGE C ANDREWS I was impressed by the apparently infected lower teeth All the upper teeth have been pulled out The patient never had roentgenograms taken of his lower teeth His gums are retracted and show definite gingivitis, and I suspect that he has root abscesses I agree with those who prefer manual epilation and quinolor® ointment If sulfonamide drugs were not

DR FRANCIS PASCHER We now have 9 or 10 patients at the Skin and Cancer Unit who have been treated with calciferol for lupus vulgaris for approximately six months to one year About 75 to 80 per cent improvement is attained in about six to eight months of treatment, and then progress is much slower, or seems to come to a standstill The problem of how to treat the residua presents itself

DR ANTHONY C CIPOLLARO Calciferol certainly is not a cure-all for cutaneous tuberculosis, but it is the best remedy that dermatologists have ever had to combat this disease, as well as lupus erythematosus and other tuberculodermas It is also interesting to note that calciferol is derived from irradiated vegetable ergosterol and so is related to ultraviolet irradiation Up to the present the only effective treatment for lupus vulgaris has been ultraviolet irradiation, especially as carried out at the Finsen Institute at Copenhagen Now there is a remedy derived through the action of ultraviolet irradiation on ergosterol

DR RUDOLF L BAER In connection with the superficial nodules remaining after treatment with calciferol, Lomholt has recently advised a combination of calciferol and Finsen treatment Apparently the deep nodules cannot be reached by the Finsen treatment, and the superficial ones cannot be reached by calciferol He believes that the combined treatment may solve the problem

DR CHARLES WOLF One must always be on the lookout for atheromas of the capillaries of the kidney especially, and also of the smaller vessels of the myocardium Patients given calciferol and calcium should have frequent determinations of the blood calcium Where there are residua, an ointment containing 3 per cent calciferol is effective

DR MARION B SULZBERGER The answers to most of the questions asked are to be found in the recent literature At the New York Skin and Cancer Unit we used dosage schedules of 600,000 units, three times for the first week, twice for the second, third and fourth weeks and once weekly thereafter because we think it essential to work along the exact lines a predecessor has followed, to repeat as accurately as possible what was done originally, in order to see whether we obtain the same results as the original observer So we went to great pains to use the same doses and preparations as Charpy, getting the solutions of sterogyle 15® (vitamin D preparation) from France and treating our patients in the same way as was done there Then, having fully confirmed what earlier observers have said, we then used other preparations of vitamin D_2 and used modified dosage schedules I would hazard a guess that the optimum dosage might be different in each case, as with gold compounds and the arsenicals I think that the future and fundamental study of this form of treatment is important We know that this vitamin schedule is effective in some cases of sarcoidosis Is that an added argument in favor of the thesis that sarcoid is some form of tuberculous infection, or is vitamin D_2 (calciferol) also good for other types of granulomas not due to tubercle bacilli? If so, it might be good for tuberculoid leprosy, and many other important granulomatous infections At my suggestion, Dr Wade is planning to try it out in the tuberculoid and lepromatous forms of leprosy Will vitamin D_2 be valuable in treatment of any types of tuberculosis of the viscera, and if so, which forms? These and many other questions can be answered only when many investigators take up and extend this new form of treatment introduced by European dermatologists

Chronic Benign Familial Dermatosis (Hailey-Hailey) Presented by DR NATHAN SOBEL

R M, a man aged 72, is presented from the New York Skin and Cancer Unit with a rash which has been present intermittently for six years It started on the left side of the neck and now involves the dorsum of the chest, sides of the neck

used and sensitivity of the Staphylococcus to penicillin has not been tested, I would advise that this be done

DR HOWARD FOX I am grateful for this discussion I shall see that the man has a roentgenogram of his lower teeth in a search for abscesses He has certainly had penicillin to the limit From what I have read, I have come to the conclusion that penicillin is often a poor remedy for sycosis vulgaris As to fractional doses of roentgen rays, I have had poor results I think that quinolor® ointment is the best remedy, though it may have to be continued for months As Dr Cannon said, it is not feasible in cases of profuse eruption to pull out all the hairs I shall advise the patient to rub in the quinolor® ointment vigorously three times a day

Lymphogranulomatosis Benigna (Schaumann's Disease) Presented by DR FRED WISE

A A, a Negro woman aged 35, registered at the Skin and Cancer Unit April 4, 1946, presenting lesions of four months' duration The patient had smallpox at 8, therapeutic abortion at 16 and supravaginal hysterectomy at 28 years She complains of weakness, cough, anorexia, constipation and nocturia During the past eight months she lost 33 pounds (15 Kg) in weight

On both parotid areas are symmetric hen's egg-sized fixed swellings Axillary and epitrochlear lymph nodes are enlarged The liver is enlarged to 3 finger-breadths below the costal margin The spleen is palpable and hypertrophied

Examination showed a pea-sized, raised, painless, nontender nodule on the upper lip and one on the chin, ten similar nodules are located on the small of the back and scattered isolated growths on the trunks and extremities Herpes zoster, in the form of a vesicular erythematous eruption, extends along the entire left sixth rib

The hemogram was normal Routine examination of the chemical content of the blood revealed 8 5 mg of urea nitrogen (normal 25 to 35), 21 mg of nonprotein nitrogen in one hundred cubic centimeters of whole blood (normal 160 to 230), 230 mg of cholesterol in one hundred cubic centimeters of plasma The icteric index was 7 1 The cephalin-cholesterol flocculation test gave a plus-minus result

Roentgenograms of the long bones showed small cystlike areas at the heads of several phalanges of both hands Examination of the eye revealed an enlargement of the peripheral portion of both lacrimal glands The orbital portion on the left side had a shotty feel On retracting the lower eyelid several match-head-sized nodules are exposed and hyaline-like excrescences at the upper borders of the tarsi of both lids are present There is no uveitis or iridocyclitis

The patient has chronic atrophic nasopharyngitis with suspicious small nodules on the uvula and a nodule on the laryngeal surface of the epiglottis and on the anterior commissure of the subglottis

The histologic section from one of the lesions showed Boeck's sarcoid Dr Charles F Sims interpreted the observations as follows The epidermis is somewhat flattened Throughout the upper middle part of the cutis and extending downward into the deep part of the corium are numerous well defined cellular masses composed of epithelioid and giant cells These masses do not appear to be undergoing necrosis There is little small round cell infiltration

Hodgkin's or lymphoblastoma type and the type described by Lewis, which seemed to be on an allergic basis and simulated changes seen in periarteritis nodosa In the case of eosinophilic granuloma of the bone reported by Curtis there were elevated granulomatous cutaneous lesions I saw a patient today with ulcerative lesions with decided changes in the bones of the skull which makes the disease in this case similar to Hand-Schuller-Christian's disease and Letterer-Siwe's disease My co-workers and I have observed a patient with multiple small granulomatous lesions with similar cystic lesions and rarefaction in the bones In another case in which our original diagnosis was histiocytoma, there were multiple small nodular lesions in the skin resembling xanthoma and bony lesions subsequently developed in the mandible Farber of Boston groups eosinophilic granuloma of the skin, Letterer-Siwe's disease and Hand-Schuller-Christian's disease together as variants of the same process and regards any evidence of deposition of fat in the tissue as a secondary degenerative phenomenon He therefore would differentiate these conditions from xanthomatosis and diseases of lipid metabolism Some years ago, however, Weidman reported a case of xanthoma disseminatum in association with Hand-Schuller-Christian's disease, and there are other such cases in the literature so that the exact classification of eosinophilic granuloma of the bone and skin remains to be determined

Noduloulcerative Syphilid of the Chest Wall Presented by Dr Herbert Rattner and (by invitation) Dr H Rodin and Dr N L Baker

Ulceronodular Syphilis of the Abdomen Presented by Dr James R Webster and (by invitation) Dr J Graffin

A Case for Diagnosis (Pyoderma Faciale?) Presented by Dr Theodore Cornbleet and (by invitation) Dr D Cohen and Dr J Graffin

Bromoderma, Granulomatous and Acneform Presented by Dr David V Omens and (by invitation) Dr Harold D Omens and Dr J Graffin

A Case for Diagnosis (Blastomycosis? Bromoderma?) Presented by Dr Francis E Senear and staff

Lymphangiectasis of the Vulva Presented by Dr Herbert Rattner and (by invitation) Dr H Rodin and Dr N L Baker

A Case for Diagnosis (Lichen Striatus? Nevus?) Presented by Dr Theodore Cornbleet

A Case for Diagnosis (Meleney's Ulcers or Pyoderma Gangrenosum?) Presented by Dr Theodore Cornbleet and (by invitation) Dr H Shorr and Dr N L Baker

Squamous Cell Epithelioma at the Site of Old Lupus Vulgaris Which Had Been Treated with Roentgen Rays Presented by Dr Theodore Cornbleet and (by invitation) Dr David Cohen

Pityriasis Lichenoides of Juliusberg Presented by Dr E A Oliver

Parapsoriasis Guttata (Pityriasis Lichenoides Chronica) Presented by DR STEPHEN ROTHMAN and (by invitation) DR Z FELSHER and DR R SNAPP

Pityriasis Lichenoides Chronic Varioliformis Presented (by invitation) by DR MAURICE OPPENHEIM and DR W A YACULLO

Pityriasis Lichenoides et Varioliformis Acuta Presented by DR EDWARD A OLIVER and (by invitation) DR A B HENNINGSEN

Lupus Miliaris Disseminatus Faciei Presented by DR EDWARD A OLIVER and (by invitation) DR H F GARRARD

Sarcoidosis, Cutaneous Lesions of Boeck and Darier-Roussy Type Presented by DR FRANCIS E SENEAR and staff

A Case for Diagnosis (Acrodermatitis Atrophicans Chronica?). Presented by DR FRANCIS E SENEAR and staff

A Case for Diagnosis (Keratosis Pilaris?) Presented by DR M H EBERT and (by invitation) DR VERA LEAF

Pustular Psoriasis Presented by DR M R CARO, DR STEPHEN ROTHMAN and (by invitation) DR R SNAPP

Cicatrizing Alopecia Presented by DR DAVID V OMENS and (by invitation) DR HAROLD D OMENS

Leukemia Cutis Presented by DR FRANCIS E SENEAR

Francis W Lynch, M D, *President*

Leonard F Weber, M D, *Secretary*

May 21, 1947

A Case for Diagnosis (Erythrasma?). Presented by DR T CORNBLEET and (by invitation) DR H SCHORR and DR J GRAFFIN

Granuloma Inguinale Treated with Streptomycin Presented by DR M H EBERT and (by invitation) DR N BAKER

O N, a Negro aged 46, has been ill for fifteen years He has been a bed patient in the Cook County Hospital for the past twenty-eight months He was admitted in January 1945 with extensive ulceration of the inguinal areas, scrotum and perineum Smears of these areas showed Donovan bodies From July 1946 to February 1947 he was treated with podophyllum solution (20 per cent in liquid petrolatum) with some improvement On April 18 treatment with streptomycin was begun and given for one month, 120,000 units every three hours The process on the inguinal areas and scrotum has healed, on the perineum there is still a small ulcer (3 by 5 cm)

DISCUSSION

DR HENRY E MICHELSON (by Invitation) I was glad to have the opportunity of seeing this patient I agree with the diagnosis of Schaumann's disease, and I think that some common term should be used for all of these sarcoid conditions, like sarcoidosis I think that this disease is a general condition, not necessarily a system disease, for the various systems most commonly involved are the lymph nodes, skin, lungs and bones However, even the meninges may be involved There is still much studying to be done on the subject It is strange that the Scandinavians see so much in their country and here the disease is seen so commonly in Negroes I feel that one should take a broad view of this disease, have an open mind as to causation and not expect the histologic picture to be as precise as has been believed in the past The course of sarcoidosis is variable some patients having complete remissions and some having the disease for many years

DR. MAURICE J COSTELLO I think that the herpes zoster in this case is an interesting feature and that it is due to pressure on the posterior nerve roots by the lesion of this disease A similar mechanism occurs in Hodgkin's disease

DR. ANTHONY C CIPOLLARO It is my understanding that in a number of these cases pulmonary and even miliary tuberculosis develops later

DR FRED WISE I am grateful for this discussion, from which I have gained considerable knowledge The only point against the established diagnosis of Schaumann's disease is the absence of uveitis perhaps the process is not sufficiently advanced to have caused this symptom I have in mind fever therapy for this patient

A Case for Diagnosis (Annular Atrophic Lichen Planus? Scleroderma?). Presented by DR FRED WISE

Epidermolysis Bullosa, Spina Bifida Occulta, Vitamin Deficiency Associated with Ichthyosis Presented by DR A BENSON CANNON

A Case for Diagnosis (Sarcoid? Granuloma Annulare?) Presented by DR. FRED WISE

Epidermolysis Bullosa Confined to the Palms and Soles Presented by DR MAURICE J COSTELLO

L C, a girl aged 19, has had recurring large thick-walled painful bullae on the bearing surface of the feet and on the palms since she was 3 years of age The eruption on the soles is present mainly in the spring and summer, when she is more inclined to walk Blisters occur on the palms at points of pressure after such household duties as ironing clothes In addition, she presents a number of calluses on the pressure points of the dorsal aspect of the toes There is some redness and scaling of the dorsal aspect of the last phalanx of the fingers The feet have an aged appearance Yesterday it was observed that, in addition, the patient complains of chapping, redness and scaling of the lower third, anterior surface of the legs and the tip of the nose in cold and windy weather Treatment has been palliative, consisting of rupturing the vesicle and use of potassium permanganate foot baths

A Case for Diagnosis (Lichen Planus Pilaris? Parapsoriasis? Premycotic Stage of Mycosis Fungoides?) Presented by DR MAURICE J COSTELLO

Eosinophilic Granuloma of Pituitary Gland, Lungs, Bones of the Skull, and Skin Presented by DR GEORGE M LEWIS

M T, a woman aged 33, is presented from New York Hospital She was well until ten years ago, at which time she had severe polydipsia, polyuria, amenorrhea and loss of libido, clinically typical of diabetes insipidus Roentgen studies disclosed a normal sella turcica, but there were multiple rounded areas of destruction in the occipital and parietal bones, compatible with the diagnosis of eosinophilic granuloma of bone Similar lesions were demonstrated in the frontal region three years later At this time a necrotic area was found in the mandible, and on section it was found to be typical of eosinophilic granuloma of bone with "fairly dense connective tissue which was diffusely infiltrated by myelocytes of various forms and a great number of eosinophils" Four years after first observation, roentgen therapy, in a dosage of 400 r, was given to the osseous lesions of the skull and resulted in their complete involution There was no improvement in the diabetes insipidus following roentgen therapy, and symptoms, partially controlled by pitressin® (a preparation of the pressor principle of the posterior lobe of the hypophysis), have persisted to date

Granulomatous vulvar lesions were first noted four years after the onset of the disease These have gradually become more pronounced and extensive to date, six years later Eighteen months ago burning and redness were noted in the axillas and have been followed by the gradual development of granulomatous lesions similar to those on the vulva During the past four months low grade paronychial lesions and gradual destructive changes in the finger nails and toe nails have occurred

The axillas, vulvar region, perineum and adjacent aspects of the thighs are the seat of an extensive, moist, hypertrophic and vegetating granulomatous process The paronychial tissues are reddened and exude purulent material The nail substance has largely disappeared Chronic gingival lesions, now cleared, have resulted in the gradual loss of all the teeth

Repeated blood cell counts have revealed slight secondary anemia and inconstant, moderate leukocytosis Eosinophilia has never been detected Sternal marrow study was within normal limits Results of serologic tests of the blood were negative on several occasions Total protein was 8 Gm, the albumin-globulin ratio was 4 9 to 3 1, cholesterol values were normal Cultures from the granulomatous lesions have revealed hemolytic Staphylococcus aureus and Staphylococcus albus, nonhemolytic streptococci and a gram-negative bacillus resembling Bacillus Ducreyi Results of examination of curetted tissue for Donovan bodies were negative The reaction to the Frei test was negative Routine roentgen examination of the chest eight months ago showed a diffuse generalized eosinophilic infiltration in both lungs Results of examinations of the stool for ova and parasites have been negative on two occasions

A section taken from granulomatous lesions showed numerous large mononuclear cells, plasma cells and eosinophils, the latter occurring both perivascularly and diffusely through the section Moreover, eosinophilic granules were noted lying free in the tissue The blood vessels were the seat of extensive endarteritis

While the eosinophilic granulomas of bone disappeared after roentgen therapy, there has been no improvement in the diabetes insipidus to date The patient has

DISCUSSION

DR GLORGE C ANDREWS I have as patients a brother and sister who have this disease limited to the palms and soles They have atrophy of the phalanges and the skin of the hands and feet The brother has some other lesions on his body but the sister has lesions only on her palms and soles My patients have atrophy and bullae, and atrophy of the digits, and present definite epidermolysis bullosa of fifteen years' duration This patient to my mind has hyperkeratosis and bullae I am not sure whether she has epidermolysis bullosa I presented a similar case before the New York Dermatological Society on Jan 23, 1945

DR J GARDNER HOPKINS This case reminds me of one reported in the November issue of THE ARCHIVES, also under the same diagnosis, with the disease limited to the palms and soles, but with no other signs of epidermolysis bullosa, and I wonder whether it was really that disease

DR HOWARD FOX I agree with Dr Hopkins I have received a number of articles from men in the Army or Navy describing cases with the condition limited mostly to the soles These men have eventually had to be discharged from the service They were often considered to be suffering from dermatophytosis at the outset, but eventually the correct diagnosis was made

DR MAURICE J COSTELLO This patient presents lesions almost at will After ironing clothes for a time large bullae develop on her palm, and always after walking three or four blocks bullae develop on her soles I have seen quarter-sized and half-dollar-sized, thick-walled bullae on her palms and soles

Widespread Papulosquamous Eruption, Neurosyphilis Presented by DR A BENSON CANNON

V V, a 42 year old Puerto Rican woman, was admitted to City Hospital for a generalized rash of three months' duration She had been in good health until three months prior to admission, when she suddenly began to experience severe frontal headaches, fever, malaise and anorexia At the same time there appeared a rash on the flexor surfaces of the arms and forearms The rash spread rapidly and became generalized The patient did not receive any therapy She was admitted to the hospital on April 15, 1946, having been referred from the Vanderbilt Clinic

The patient has been a widow for three years She has five children, all in good health The oldest is 25 years of age and the youngest 9 years One miscarriage occurred seven years ago

Physical examination discloses a well nourished Puerto Rican woman There is a generalized papulosquamous eruption involving the entire cutaneous surface, including the palms, feet and face Lesions are symmetric and superficial They are brownish red and covered with adherent scales The lesions resemble psoriasis The mucous membranes are not involved There are no lesions in the throat There are no lesions in the genital or anal regions The pupils react in accommodation but not to light The knee jerk is exaggerated, the ankle jerk is present The Romberg reaction is negative

The Ducrey and Frei reactions were negative Examination of the spinal fluid showed 12 cells, 0 01 per cent protein, colloidal gold 4444321000 Results of dark field examination of material from the lesions were negative on April 16 The Kline reaction of the blood was 4 plus on April 12 The Wassermann

gained 25 pounds (11 Kg) in the past ten years The cutaneous lesions have shown gradual improvement following various types of local therapy and the administration of roentgen rays

DISCUSSION

DR GERALD F MACHACEK I do not wish to take issue with the diagnosis, but there are indications here of what might be called multiple myeloma From a section of the skin, and taking into consideration that the blood cell count was within normal limits, I think that the changes suggest aleukemic leukemia, from the many monocytic cells within the vascular lumens

DR MAURICE J COSTELLO I think that Dr Lewis, about three years ago, presented a case of eosinophilic granuloma confined entirely to the skin, with a large tumor mass on the back

DR GEORGE M LEWIS This case is almost unique in that there is authenticated involvement of bones, lungs and skin It is interesting that roentgen therapy is rapidly successful in curing the bone disease and apparently in curing the lung disease Roentgen therapy has also helped the cutaneous lesions in this patient The essential histologic changes appear in the blood vessels, which at first show swollen endothelial cells with progressive endarteritis with narrowing of the lumen The infiltrate at first is focal but later diffuse through the tissues The infiltrate also changes from a polymorphous type to one predominantly eosinophilic

Solid Edema of the Face and Neck Occurring in the Course of Infectious Eczematoid Dermatitis Presented by DR MAURICE J COSTELLO

Eugene F Traub, M D, *President*
George M Lewis, M D, *Secretary*
Jan 28, 1947

A Case for Diagnosis (Melanoma?) Presented by DR PAUL E BECHET

V P, a woman aged 53, stated that sixteen years ago she noticed a small tumor on her right cheek which increased considerably in size within a year It was removed but in what manner she does not remember Two years later it recurred, and in the past thirteen years no attempt has been made to treat it In the past year the patient states that the lesion has increased in extent On inspection, she presents a dark red patch about 50 mm in diameter, with a distinct, elevated and indurated border and in its upper part a black, sharply outlined, somewhat raised, rounded area about 30 mm in diameter The patient states that the melanotic features have been present for six years Her health is good, and there is no evidence of metastasis anywhere There are no similar lesions elsewhere on her body

DISCUSSION

DR JOHN C GRAHAM I would have a plastic surgeon remove the lesion, which is commencing to show malignant changes It is undoubtedly melanotic, and I think it should be widely removed and a graft set in

DR MAURICE J COSTELLO As the lesion has been present for sixteen years, I would be inclined to do nothing radical It may last another sixteen years

reactions of the blood and the spinal fluid were both 4 plus on April 16 The patient has received 4,000,000 units of penicillin, 100,000 units every three hours

DISCUSSION

DR RAY H RULISON It is rather curious that, in a person obviously with neurosyphilis and with Argyle Robertson pupils, there should be such an extensive syphilitic eruption as this Cutaneous eruptions are relatively rare in neurosyphilis How would this eruption be classified, assuming it to be a syphilitic eruption?

DR A BENSON CANNON One frequently sees involvement of the nervous system in cases of early syphilis and especially in the late secondary stage This patient's cutaneous lesions have greatly improved with penicillin

NOTE—The diagnosis from biopsy of the cutaneous lesion was syphilis All lesions disappeared after the penicillin injections

Acanthosis Nigricans Presented by DR FRED WISE

A S, a boy aged 12, registered at the Skin and Cancer Unit on April 16, 1946, presenting cutaneous lesions of eight months' duration He has two brothers, aged 5½ and 3½ years, who do not have any cutaneous disease He had measles, chickenpox, scarlet fever, German measles and mumps during childhood and a streptococcic infection of the throat and recurrent infections of the left ear His appendix was removed at the age of 10 He was also subject to mild attacks of hay fever His maternal grandmother died at the age of 56 from a tumor of the kidney which became polycystic The paternal grandmother had a kidney removed "for some ailment," and two years later the other kidney became affected and she died at 52 The paternal uncle died at 35 after a kidney removal Both grandfathers died of "heart attacks" Obesity is a familial trait Most of the members of the family from the grandparents down have been and are obese

The mother stated that the child's neck was always darker than the rest of the body, and this was thought to be due to exposure to the sun The boy is of average intelligence He feels strong and well, except for occasional attacks of frontal headaches

A "sore" area first developed on the right side of the neck, this would clear up for a week or two and then recur after he wore rayon shirts or used soap When he avoided rayon shirts and soaps the soreness would regress, leaving rough areas which would become rougher after each attack of soreness Two months later the patches began to spread around the neck The pigmentation in the axillas appeared at the same time as those on the neck The patch on the left cubital region developed about two months ago

Examination shows blackish pigmentation on the neck, axillas and left cubital region The neck shows black dry nontender somewhat infiltrated patches which are irregular in outline, ill defined and intermingled with depigmented patches They feel rough, like sand paper The pigmented areas blend gradually into the surrounding integument There are similar symmetric patches in both axillas, blackish brown, and well defined, silver dollar-sized, dull brownish patch in the

I have had at least half a dozen patients in my practice for whom the diagnosis of malignant melanoma was made and confirmed by histologic study who have done well One has survived six years, a second nine years and a third ten years

DR GEORGE C ANDREWS I have seen superficial lesions of this character which continue for a long time However, I believe that the histologic diagnosis would be melanoma

DR. GEORGE M LEWIS If melanoma is seriously considered here, transillumination is a valuable method to demonstrate the extent of the lesion It is my impression that the lesion is a pigmented basal cell epithelioma or possibly a pigmented nevus and not a melanoma

DR PAUL E BECHET I greatly appreciate the discussion because of the involved therapeutic problem The fact that the lesion has been continuously present for thirteen years, with increase in size only in the past year, does in my opinion prove the presence of a low grade or transitional type of malignant process The patient denies the existence of any lesion on her cheek prior to the present one, so that it apparently occurred d'emblée sixteen years ago The opinions expressed in the discussion are somewhat divided as to whether or not one should intervene I shall take them carefully under consideration before making a decision, but my impression is that we are dealing with a malignant lesion which, though present for sixteen years with no apparent metastasis or much increase in size, remains potentially dangerous and that it would be better to excise it widely and subject the tissue to microscopic examination than to leave it severely alone, with possible fatal results in the future

Necrobiosis Lipoidica (Without Diabetes) Presented by DR GEORGE M LEWIS

Leukoplakia of Buccal Mucosa (Excellent Result from Treatment with Electrodesiccation) Presented by DR A BENSON CANNON

Tuberculoid Leprosy. Presented by DR. MAURICE J COSTELLO

E P, a boy aged 5, from Willard Parker Hospital, was born in Puerto Rico His father died of pulmonary disease, and his mother is in a leprosarium in Puerto Rico She has had the disease at least seven years The boy was brought to New York by plane via Miami on June 23, 1946 He had about a dozen somewhat hyperpigmented, sharply circumscribed, dime to quarter-sized lesions with a thin, raised border These lesions are anesthetic to cold, heat, touch and the prick of a pin The ulnar nerves are enlarged, and the greater auricular nerve can be palpated

The Wassermann reaction of the blood was negative, as were the reactions to the Kline diagnostic and Kline exclusion tests Nasal scrapings were sterile Biopsy of one of the lesions showed the corium in the center of the section to be granulomatous, consisting of pale mononuclear cells, some with foamy cytoplasm, and a small number of lymphocytes Occasional fibroblasts were present in the periphery of the lesion The character of the granuloma was identical with the leprous lesions from our material at the hospital, but no acid-fast bacilli were found in the section with Fite stain (Dr Vero Dolgopol)

left cubital region On diascopic pressure there is no change in intensity of color

He is overweight His height is 5 feet and 5¾ inches (164 4 cm), and he weighs 172 pounds (78 2 Kg) stripped The abdomen is pendulous The breasts are prominent and the nipples retracted The genitals are small for his age Scrapings of the patches in the cubital region and axillas were negative for tinea on direct examination and culture

A histologic section taken from a hyperpigmented lesion on the neck according to Dr Charles F Sims showed the features of acanthosis nigricans for the most part, except for the absence of pigment He suggested that avitaminosis A be considered He stated that the epidermis was verrucous The granular layer was in part thickened and in part thinned, and at one or two points absent The epidermis was moderately and irregularly acanthotic with considerable interlacing of the rete pegs The basal margin did not present much pigment, as suggested by the clinical diagnosis There was a diffuse reaction in the papillary zone and a perivascular one in the subpapillary zone composed of small round cells, wandering connective tissue cells and scattered chromatophores Some interstitial and parenchymatous edema of the papillary zone were observed

DISCUSSION

DR HENRY E MICHELSON (by invitation) One reads in the literature of children with acanthosis nigricans occasionally experiencing something like the Cushing syndrome, but I think that the lesions of children with this disease will heal without any trouble

DR HOWARD FOX The opinions that these lesions are benign are different from those expressed at the last meeting At that time, some members stated the opinion that some of these cases terminate fatally

DR HANS J SCHWARTZ The case that I reported some time ago was not of the juvenile type The patient was followed up at the Memorial and New York hospitals and died at the age of 53 years The case had been regarded as one of juvenile acanthosis nigricans, but autopsy showed an enlarged liver which proved to be carcinomatous

DR WILLIAM CURTH (by invitation) I think that most of these cases of benign diseases continue without becoming cancerous In the cases of malignant disease there can be an interval of eight to ten years between the appearance of the cutaneous lesions and the manifestation of the cancer

DR FRED WISE The consensus is that in these juvenile cases as a rule complications do not develop, but the patients have to be kept under observation until they reach maturity and adulthood

A Case for Diagnosis (Dermatitis Factitia of Both Feet) Presented by DR EUGENE F TRAUB

Rosacea-like Tuberculid of Lewandowsky Presented by DR FRED WISE

Tuberculous Ulcerative and Fungoid Lesions of Buttocks and Perineum Presented by DR FRED WISE

Dr Jackson claimed that she isolated gram-positive, non-acid-fast forms from the cutaneous lesions It is interesting to note that this patient, though exposed to acute contagious diseases while at the hospital, did not become infected with any of them

DISCUSSION

Dr Gerald F Machacek I saw the child several months ago and suggested treatment with streptomycin with hesitation, as this is a "benign" form of leprosy

Dr Frederick Reiss (by invitation) I believe this case is one of typical minor tuberculoid leprosy

Dr A Benson Cannon I suggest that the patient be treated with diasone® by mouth, beginning with small doses and gradually increasing the dosage Dr Faget reports excellent results in the treatment of leprosy with that drug and states that it is less toxic than other preparations He states that the patient must take the medicine for six months or longer before improvement can be noticed

Dr Maurice J Costello I have tried streptomycin in cases of this disease, without the slightest benefit

Granuloma Inguinale of the Mouth and Genitalia Presented by Dr A Benson Cannon

E S, a Puerto Rican woman aged 26 who has been in the United States for six years, was admitted to the City Hospital on Jan 9, 1947, complaining of sores in the mucous membranes of the mouth, lips and anal-genital region of twelve months' duration The patient has been separated from her husband for five years She has never been pregnant. The past and family histories are essentially noncontributory

The present disease began with a small ulcer near the anus twelve months ago, which gradually increased in size, spreading around the anus and the crotch to the front and involving the inguinal regions and the vulva with an extensive ulceration which is painful on motion

Note—Donovan bodies were subsequently found in the oral lesions and also in the genitocrural ulcer The patient was given three small blood transfusions of 250 cc each and an injection of fuadin® every day The improvement has been spectacular There was immediate relief from pain, so that the patient eats well, can walk and has gained 20 pounds (9 1 kg) in weight On February 24 most of the oral lesions were gone and those in the groin were noticeably better Of the last 65 patients with granuloma inguinale admitted to hospitals, this is the second to have lesions of the oral cavity

Fox-Fordyce Disease Alopecia Areata Presented by Dr George C Andrews

R M W, a Negro woman aged 20, single, is presented from the Vanderbilt Clinic She was first seen in October 1946, with a pruritic eruption of one year's duration, which had appeared after taking injections from her private physician to "stimulate hair growth" Episodes of partial loss of hair had recurred over a period of ten years The eruption began in the axillas and had spread to involve other areas There has been no exacerbation at the time of the menses, which have been regular until the past month, when a mild metrorrhagia occurred

Eugene F Traub, M D, *President*
George M Lewis, M D, *Secretary*
Nov 26, 1946

Lupus Erythematosus Presented by DR ANTHONY C CIPOLLARO

R P, a boy aged 3, was first seen by me on Nov 15, 1946, with an eruption on the face which the mother thought followed mosquito bites The eruption appeared on both cheeks and finally spread across the nose After about two weeks the child was taken to the Skin and Cancer Unit, where a blood cell count, tuberculin tests and a biopsy were performed

The blood cell count showed mild secondary anemia The reactions to tuberculin tests were negative in dilutions of 1 1,000,000, 1 500,000 and 1 100,000 The report of biopsy of the right ear lobe was "inflammatory phase of lupus erythematosus"

The patient now presents an erythematous eruption involving both cheeks and most of the nose The shape of the eruption roughly resembles a butterfly There are telangiectatic vessels, and the scales are dry and adherent The lesions are sharply demarcated

Iodized salt was prescribed and the application of a sulfur preparation to the affected areas Within two weeks the eruption improved at least 75 per cent

DISCUSSION

DR PAUL E BECHET There is no doubt that the location is the usual one for lupus erythematosus and the scaling is characteristic, but the eruption lacks the follicular keratoses that one sees in the discoid type of lupus erythematosus This may be explained by the fact that the skin of young children is less apt to have keratotic lesions than the skin of adults I agree with the diagnosis The interesting thing is the age of the patient It seems to me that the incidence of lupus erythematosus in young children is greater today than it was years ago, and I believe that this is due to the increased tendency to exposure to the sun

DR RAY H RULISON I think that it is lupus erythematosus, probably of a superficial type

DR HOWARD FOX I agree with the diagnosis, particularly because histologic examination of one of the lesions confirmed it I do not agree with Dr Bechet that this disease is frequently seen in children It is most extraordinary to see 2 cases in babies at one meeting At least, it has never happened in my experience

DR GERALD F MACHACEK I do not know what else I would call this but lupus erythematosus Several years ago I saw 2 fairly well nourished children of this age group with lesions that were not as scaly as these but had the same distribution and also developed after exposure to sunlight The diagnosis was lupus erythematosus These children were on a diet of bananas, but appeared well nourished I do not know what ultimately happened, but I understand that they improved after the diet was varied The only clinical diagnosis I could make in the case presented by Dr Cipollaro would be lupus erythematosus, but I should consider the possibility that it might be due to or precipitated by some dietary imbalance, perhaps avitaminosis

DR A BENSON CANNON I agree with Dr Fox that lupus erythematosus in infants must be an exceedingly rare disease I do not recall having seen a typical

There are many areas of alopecia in the occipital region of the scalp An eruption consisting of discrete conical papules is present over the lower mandibular region and on the sides of the neck, axillas, breasts and periumbilical, pubic and perianal regions Secondary lichenification is present

Histologic examination of tissue from between the breasts was consistent with a diagnosis of Fox-Fordyce disease A second biopsy has recently been made of material taken from the side of the neck, but the results have not yet been reported

Treatment has consisted of antipruritic agents locally, and administration of roentgen rays, which gave only temporary relief Pyribenzamine® and benadryl® have been given since Dec 16, 1946, and the patient has experienced considerable relief since the dosage has been increased to 100 mg of pyribenzamine® three times daily with 100 mg of benadryl® at bedtime

DISCUSSION

DR A BENSON CANNON This patient was presented at the Vanderbilt Clinic conference, and the consensus of the group was that while the eruption might be that of Fox-Fordyce disease it was certainly most atypical While the lesions in the axillas did simulate Fox-Fordyce disease, there was so much lichenification of the skin and the eruption was so widespread on the neck, chest and abdomen, where no apocrine glands are supposed to exist, that one should suspect an additional dermatitis probably caused by treatment I think that benadryl® is most beneficial in relieving highly nervous patients, and especially those with pruritus, but I doubt whether it has any desensitizing effect in allergic states There is an increasing number of reports of unfavorable reactions and even addiction to benadryl,® so that one should be cautious in prescribing it, especially over long periods

DR GEORGE M LEWIS I should like to suggest the diagnosis of alopecia marginalis

DR MAURICE J COSTELLO We see Negro women at Bellevue Hospital rather frequently who have this condition I think it is traumatic marginal alopecia They put up their hair at night in tight crimpers I have seen it in white women also who fix their hair in a similar manner and dress it in the so-called up-sweep fashion

DR GERALD F MACHACEK I am of the opinion that it is Fox-Fordyce disease The material taken for the second biopsy did not go deep enough to include the acini of the gland, but most of the pathologic change is around the outlets The first biopsy showed an apocrine gland and the neurodermatitic changes which I would not expect in Fox-Fordyce disease

Bowen's Disease (Two Large Lesions, One on the Shoulder and the Other on the Leg). Presented by DR MAURICE J COSTELLO

ALSO PRESENTED

A Case for Diagnosis (Tuberculosis?) Presented by DR EUGENE F TRAUB

Lymphocytoma Presented by DR GEORGE C ANDREWS

case of lupus erythematosus in a child under 3 years of age I think that it is necessary to observe such an eruption for some months and to have a biopsy made before one can be certain of the diagnosis of lupus erythematosus in infants Recently a baby was admitted to the hospital with the diagnosis of lupus erythematosus, but it proved to be infantile eczema In the case presented, the location and character of the lesions suggest the diagnosis of lupus erythematosus and the report of biopsy supports that diagnosis I should suggest, however, that the patient be observed longer and that another biopsy be made

DR JOHN C GRAHAM I think that it is lupus erythematosus, clinically at least I have never seen a similar case

DR MAURICE J COSTELLO I think that the patient has lupus erythematosus, and I think that it is the disseminated type, as there are lesions on the external surfaces of the forearms as well as on the face and neck It is the type of lupus erythematosus that will have to be watched carefully It would not be advisable to administer gold salts to this patient

DR FRANK C COMBES I agree with the diagnosis Of course, the youngster does look undernourished I agree with Dr Machacek, and there might also be an investigation as to tuberculosis in this family and in the child himself

DR GEORGE C ANDREWS The delicate character of this child's skin should be noted About two summers ago I saw 2 children, about 2 or 3 years of age, with lupus erythematosus One was in New York Hospital for a month under observation, and the diagnosis was well established These patients have both improved I have seen them within the past six months The improvement was great with proper diets, with a great deal of vitamins, wheat germ and injections of crude liver extract Both have slight traces of disease but are greatly improved They had the extensive discoid type of lesions on the face

DR NIELS DANBOLT, Oslo, Norway (by invitation) I agree with the diagnosis It is surprising to see lupus erythematosus in such small children I am of the opinion that you see more of this disease here than we do in Norway I can not understand why you use the name "lupus" In Scandinavia we have dropped that misleading term altogether and call it just "erythematodes"

DR GEORGE M LEWIS From the clinical features presented, I would favor lupus erythematosus over other diseases with which the disease could be confused

DR EUGENE F TRAUB My co-workers and I saw this patient at the New York Skin and Cancer Unit several months ago, within a short time following his summer exposure to sun He presented a classic type of discoid lupus erythematosus, and the features that were present then, namely, the dilated follicular plugs and what appeared to be superficial atrophy, are not so apparent now A biopsy was performed to confirm the diagnosis chiefly because of age of the patient

DR ANTHONY C CIPOLLARO I also thought that lupus erythematosus was extremely rare in children of 3 and under, and for that reason I am presenting 2 cases I think that the diagnosis has been well established in this case, both clinically and histologically, and I should also like to emphasize the improvement which followed treatment with iodized salt

Ulcer (Postdesiccative, Left Thumb) Xeroderma Acarophobia Neurotic Excoriations Presented by DR GEORGE M LEWIS

A Case for Diagnosis (Behcet's Syndrome? Pemphigus? Leukemia Cutis?) Presented by DR EUGENE F TRAUB

I M, a man aged 52, has been previously presented He was first seen at the Skin Clinic of the New York Post-Graduate Hospital in 1930 when on otolaryngologic examination bullous lesions were discovered on his palate About the same time the patient noticed a sensation of stiffness of the upper lip He then reported to my office, where he has since been a private patient

On Aug 7, 1931, the patient presented an ulcerative lesion on the roof of the mouth, of long duration, which finally healed after wide endotherm removal In 1932, erythematous, scaly lesions appeared on the upper lip and in both nasolabial folds Tonsillectomy was performed Apart from the period 1932-1934, during which time the patient was entirely free of lesions, there was a continuous appearance of lesions in the mouth and buccal mucosa, as well as on the mucosa of the hard and soft palate, together with erythematous, scaly, psoriasiform lesions on the lips, nasolabial folds, eyebrows and penis

On the buccal mucosa at present there are several rounded, denuded areas about 1 to 1 5 cm in diameter The uvula is thickened and shows small ulcerations There are ill defined, confluent, polycyclically outlined ulcerations on the eyebrows, lips and glans penis, with flat, necrotic, scaling, moderately infiltrated, erythematous lesions The region around the chin is diffusely involved by a brown-red, scaly, infiltrated erythema

Results of urinalysis and Wassermann tests of the blood on many occasions have been negative, as were smears for Vincent's organisms and cultures for

baby was 3 months old, and since then it has spread persistently, without remissions, up to its present extent About four months ago lesions appeared on both forearms The child is decidedly undersized At the age of 15 months she weighed only 13 pounds (6 Kg) The baby was born without complications, and there were no unusual symptoms either before or after delivery

The patient presents an erythematous eruption involving both malar regions and extending across the bridge of the nose There are telangiectatic vessels and dry adherent scales, and the lesions are sharply demarcated There is one small lesion on the scalp and one small patch on each forearm A biopsy was not performed The patient was seen by me once, and then not again until the present time

Bismuth compound injections were advised, but the baby's pediatrician had read of the toxic effects of bismuth, causing death in 1 case, and he was therefore hesitant about using it Injections of crude liver extract were then recommended

DISCUSSION

DR GEORGE C ANDREWS I agree with the clinical diagnosis, although I am not as positive as in the other case I should like to call attention again to the fact that the child's skin is delicate and different from that of the mother, who has a coarse skin That was true in my 2 cases

DR FRANK C COMBES I agree with the diagnosis and think it represents a remarkable improvement

DR MAURICE J COSTELLO I question the diagnosis This child must have some developmental defect which also affects the skin She does not appear to be a sick child I think that it is a cutaneous manifestation of a developmental defect, such as the telangiectatic type of streaking seen in some major ectodermal congenital defects

DR J GARDNER HOPKINS I could not see much reason for calling it lupus erythematosus except for the involvement of the flush areas I saw no follicular plugging or hyperkeratoses There was a lesion in the elbow flexure which was eczematous, and I wondered whether it were not infantile eczema

DR A BENSON CANNON I agree with Dr Costello and Dr Hopkins that the eruption looks more like infantile eczema than lupus erythematosus The lesions are too diffuse, red, swollen and exudative for lupus erythematosus A further study of the case, including a biopsy, might help to make the diagnosis

DR GERALD F MACHACEK I am less inclined to accept this as lupus erythematosus in view of the inanition and general underdevelopment My previous remarks are even more applicable to this case

DR HOWARD FOX I agree that it is difficult to make a diagnosis in a child who is as restless as this one was The fact that the eruption began when the child was 3 months old makes it an exceedingly rare case of lupus erythematosus, if it is that disease The obvious developmental defect may have something to do with this eruption

DR RAY H RULISON Aside from the distribution, I did not find much evidence to warrant a diagnosis of lupus erythematosus

DR EUGENE F TRAUB If we are to accept this as a case of lupus erythematosus, it would have to fit into the acute disseminated type, because the patient certainly does not present any of the characteristics of the discoid type As a matter of fact, Dr Hopkins and the others are probably correct in their feeling

Monilia Results of roentgen examination of the chest, gallbladder and gastrointestinal tract were essentially normal except for a suggestion of periduodenitis and colonic hypermotility with general irritability and spasm The result of cystoscopic examination was negative for infection or tumor The results of Pels' tests on three occasions were positive

Ophthalmologic examination has shown chronic blepharokeratoconjunctivitis of unknown cause, which has recurred about every three months Topical application of penicillin has produced only temporary improvement

Blood cell counts have shown leukocytosis, with the count varying from 8,200 in 1933 to 23,500 in September 1946, with lymphocytes varying from 35 to 82 per cent

Treatment has included vitamins, acetarsone, and sulfonamide drugs given orally, with parenteral administration of neoarsphenamine, oxophenarsine hydrochloride, bismuth compound, liver, eschatin® (an extract of the adrenal cortex), moccasin venom, autogenous mixed vaccine, penicillin and typhoid vaccine and autohemotherapy His condition is essentially unchanged

DISCUSSION

DR HOWARD FOX I think that Dr Traub's suggestion of Behcet's syndrome is correct The eruption involves the three favorite areas of this disease, namely, the mouth, eyes and genitalia The disease has been extremely chronic, as it always is, and treatment has been of no permanent benefit Dr Traub has been persistent for seventeen years in trying various methods of treatment, without success

DR A BENSON CANNON This is one of the most interesting cases I have seen for a long while, and I cannot offer any better suggestion than has already been brought forward I would classify the case as one of lymphoblastoma I believe that the location of the lesions is common in leukemia, and their infiltration, the deep, verrucous ulceration on the palate and the blood cell counts would cause me to think of leukemia rather than any other form of lymphoblastoma I should suggest that another biopsy be made of the skin and one of the ulcer on the palate and that the blood and bone marrow be studied by a hematologist The slowly progressive nature of the disease, the increased total white blood cell count and lymphocyte count indicate a bad prognosis Leukemic states can last for years

DR GERALD F MACHACEK My conception of Behcet's disease is that it is a condition which recurs and is essentially vesicular The infiltration on the face makes me agree with Dr Cannon that leukemia is certainly one of the differential diagnoses that must be considered I would also suggest that the presenter check the history again to ascertain whether the patient is not taking phenolphthalein in some occult form

DR J GARDNER HOPKINS I believe that the lesions of Behcet's syndrome are ulcerations resembling aphthae This man's lesions on the penis have never ulcerated The ulcerations described by Behcet do not extend in a serpiginous manner as the lesion on the palate has done in this case Dr Cannon's suggestion that this is leukemia seems more plausible, though it is a little difficult to reconcile with the history that thirteen years ago he had a chronic ulceration on the cheek without blood changes

DR. GEORGE C ANDREWS I do not think that it is Behcet's syndrome Iritis and hypopion are not present The lesions in Behcet's syndrome, as Dr Hopkins

that this patient may not have lupus erythematosus at all, but that the hyperactivity of this child may be responsible for some of her cutaneous lesions It appears that the child rubs the face and in this manner brings about some, if not all, of the erythema and irritation The lesion on the flexor surface of the forearm is definitely edematous and vesicular and suggests either a patch of eczema or possibly even an artefact My suggestion would be for Dr Cipollaro to hospitalize the child and restrict the motions in such a way that she cannot rub her face or roll the head on the pillow and observe whether this does not cause an amelioration of the symptoms

DR ANTHONY C CIPOLLARO My diagnosis is based on two hasty observations When I saw the child the first time, I thought of several diagnoses, such as developmental defect, psoriasis, eczema and lupus erythematosus In favor of lupus erythematosus are the persistence, steady spreading, demarcation, dry adherent scales, absence of remissions and lack of vesiculation The child's pediatrician has never thought of eczema in this case The diet has been carefully supervised There is no history of atopy in the family. It is true that I did not find keratotic plugs, but in a child with a delicate skin one does not expect to find the same degree of scaliness or follicular plugging as in an adult Against eczema is the lack of vesiculation and crust formation As far as developmental defects are concerned, I could not see any evidences of nevus flammeus, and it is not like any other developmental defect I know I think that the fact that the mother is small has a good deal to do with the child's small size The evidence as I see it favors a diagnosis of lupus erythematosus I shall discuss the question of performing a biopsy with the pediatrician, and if he and the mother consent, I shall proceed with biopsy

Chronic Discoid and Lichenoid Dermatosis Presented by DR GEORGE C ANDREWS

J G, a Jewish man aged 50, was first seen Oct 9, 1946, with an eruption which had had its onset fifteen years previously, beginning with a small lesion on his thigh This had spread gradually The dermatitis had cleared with roentgen therapy, ultraviolet irradiation and various injections Exacerbations occurred at intervals but responded with the described treatment The patient has noticed also that healing occurred spontaneously during vacations in Florida There was a history of eczema during infancy Allergy testing in 1931 revealed a positive reaction only to orris root

Examination shows a patchy, vesicular, papular, erythematous discoid and lichenoid dermatitis on the body and particularly on the extremities and penis

A complete blood cell count revealed 96 per cent hemoglobin, 4,720,000 red blood cells and 5,850 leukocytes The differential smear showed 16 per cent eosinophils The urine was normal

The patient has shown no improvement with the parenteral use of penicillin, oral use of sulfapyridine, an elimination diet or arsenic trioxide solution given intramuscularly Local treatment has consisted of mild antipruritic applications and superficial roentgen therapy

DISCUSSION

DR FRANK C COMBES This man presents practically all of the characteristics one usually associates with this disease In all cases the question comes up as to

DISCUSSION

DR EUGENE F TRAUB Clinically this is not a case of pseudoxanthoma elasticum, because, in addition to being more yellowish, this disease tends to run in transverse striations along the neck and the lesions, while slightly elevated, appear to be atrophic I do not believe that the patient has poikiloderma of Civatte The characteristic telangiectatic vessels, recticulated network, small papules and peculiar pigmentation accompanying that disease are lacking here I agree that this patient has some changes which suggest either scleroderma or dermatomyositis, and there are some deep-seated, thickened rather than atrophic lesions present The patient should be studied further

Psoriasis, Granuloma Annulare, Urticaria Presented by DR ANTHONY C CIPOLLARO

Atopic Eczema, Congenital Abnormalities, Vascular Nevus, Elephantiasis, Undescended Testes Presented by DR EUGENE F TRAUB

Chronic Lupus Erythematosus (with Associated [?] Deafness) Presented by DR GEORGE M LEWIS

Infected Preauricular Branchial Cysts Presented by DR MAURICE J COSTELLO

T B, a boy aged 15, has in the preauricular regions two nearly dime-sized, slightly elevated, red, somewhat infiltrated lesions In the center of each is a tiny hole from which pus exudes on slight pressure Above and posterior to these are two oval indentations measuring about 3 mm, located at the root of the helix The latter are seen from time to time in persons with or without other congenital anomalies They are often familial They are the upper openings of the partially obliterated branchial clefts The explanation of the sinus openings is that the purulent material in these cysts drains by gravity through the skin in these locations The patient has been referred to an otolaryngologist for excision of the cysts

DISCUSSION

DR HOWARD FOX I agree with the diagnosis This infection did not go through the normal channel, and it caused an impetiginous patch where it broke through the skin

DR GERALD F MACHACEK Cancers are known to arise in branchial clefts Oncologists place special emphasis on this observation

DR EUGENE F TRAUB Injections of iodized poppyseed oil might cause trouble The tract may go much further or branch off in a different direction than is taken by the oil, so that a false impression might be obtained In addition, there are other complications from this process that render it inadvisable

DR GERALD F MACHACEK I have seen iodized poppyseed oil forced into tissue with the resultant formation of granulomas which look like sarcoids but are really similar to paraffinomas

Bullae of Epidermolysis Bullosa Occurring on a Vaccination Site Presented by DR MAURICE J COSTELLO

Mrs S B, aged 70, from the Bellevue Hospital outpatient department, was vaccinated in the left deltoid region April 14, 1947 A week later a dime-sized

whether this is a definite disease entity I think that we have seen enough cases now to justify its distinction from other dermatoses which it simulates I was interested to know that the man did not respond well to sulfapyridine We have had several patients who had good remissions definitely related to the administration of that drug

DR MAURICE J COSTELLO The only therapy I can think of which has not been tried is nonspecific therapy with triple typhoid vaccine injected intravenously I think that it would be beneficial, especially if combined with sunlight and salt water bathing, preferably in a southern climate

DR A BENSON CANNON The diagnosis of chronic discoid and lichenoid dermatosis had never occurred to me The patient is a wealthy business man with a happy disposition He has consulted me at infrequent intervals since 1933 for various minor dermatologic complaints Three years ago, I saw him for a few macular, pea-sized to five-cent-piece-sized, round to oval, scaly and crusted patches that were slightly itchy I diagnosed it as an eczematoid dermatitis due, probably, to a local irritant The lesions cleared with a few fractional doses of roentgen rays and tar ointment Since that time I have seen him every few months for a recurrence of the lesions, and there were never more than a couple of dozen After taking ocean baths in Florida and being in the sun, the patient noticed that all lesions disappeared, but these returned a few months after his return to New York Cultures for fungi were negative Patch tests elicited a strong reaction to pyrethrum, tar, phenol salicylate ointment, sulfur and several soaps Itching was never a pronounced symptom, and the lesions were always of the same character—macular, exudative, crusted areas There were never any nodules, plaques, pigmentation, lesions of the glans penis or adenopathy, symptoms that are usually found in chronic discoid and lichenoid dermatitis Tonight the patient presents many more lesions than I have observed before, but even now they are of the eczematous and crusting type

DR GERALD F MACHACEK I am of the opinion that many persons suffering from so-called chronic discoid and lichenoid dermatosis also suffer from an element of contact hypersensitivity and an element of cutaneous infection Recently in a biopsy in such a case I found a curious change in the coil glands, which appeared to be hypertrophic The inflammatory reaction seemed to reach well down into the secreting element of the gland

DR GEORGE C ANDREWS This man came to me in October, when he was worse than he is today At that time the lesions were widespread and oozing, and he was in a miserable condition He had been in Florida and knew the eruption would clear up if he went there again He said that the eruption came in cycles He is unmarried and worries a great deal He is in the textile business I have talked with his employer There is not much doubt in my mind that this is a case of chronic discoid and lichenoid dermatosis Dr Sulzberger examined him and agreed It interests me that he handles textiles, because I have another patient, a man who is a cotton goods salesman, and I know that Dr Sharlit had a patient sensitive to silk I have performed patch tests with cotton, rayon and silk, and all results were negative

DR EUGENE F TRAUB I should like the presenter to explain why these patients, particularly this one, appear to have been benefited by the warm climate Does he get anything by such a change except removal from his environment?

vaccination "take" developed, surrounded by a palm-sized area of erythema and edema The following day two marble-sized, thick-walled, tense bullae appeared on either side of the vaccination These are diagnosed as bullae of epidermolysis bullosa occurring on a site of edema and erythema and probably caused by trauma, such as scratching They were not secondary vaccination inoculations The patient has epidermolysis bullosa of the acquired type for which she has been treated for some months in the clinic Typical lesions of the disease were found on the nails, elbows, knees and other points of trauma

DISCUSSION

DR HOWARD FOX The patient shows signs of epidermolysis bullosa of the nails It does not seem like a spread of the vaccination or autoinoculation The lesions are in a region which has been more or less traumatized, and one should accept the possibility that these bullae are part of her old disease

DR PAUL E BECHET I agree with the diagnosis The trauma involved in the performance of a vaccination is enough to cause an extension of lesions of epidermolysis bullosa, which is precipitated in any location by trauma

DR RAY H RULISON I agree with the diagnosis, and I agree with Dr Combes that the trauma arises not from the superficial scarification but from the virus I can readily see how irritation and infiltration would precipitate lesions in a patient with this disease, but I have seen almost as severe reactions in persons without this disorder

DR JOHN C GRAHAM I do not quite agree with Dr Combes that scratching could not cause the lesions If her vaccination itches as mine does, she could get the blebs of epidermolysis bullosa from scratching I think that she has traumatized it

DR EUGENE F TRAUB This could well be an example of a dystrophic type of epidermolysis, and in that type particularly blisters will appear spontaneously and with the least provocation I feel that this insult was more than adequate to cause such a change and agree that vaccination was responsible

Neurofibromatosis, Ichthyosis Presented by DR GEORGE M LEWIS

Dermatitis Medicamentosa (Demerol®), Addisonian Pigmentation (Arsenical Keratosis and Pigmentation?) Presented by DR GEORGE M LEWIS

A A, a man aged 45, a former taxicab driver, had minimal pulmonary tuberculosis five years ago Two years ago a diagnosis of Addison's disease was made at the New York Hospital, and this has been treated with 6 Gm of salt and 4 Gm of desoxycorticosterone acetate daily One year ago keratotic lesions on the palms and soles were first noted Two months ago the patient had severe neuritic pains in the legs, for which he has been taking 50 mg of meperidine hydrochloride (demerol®) daily About three weeks ago a pruritic, burning, erythematous, diffuse eruption developed on the extremities and later on the trunk, and this eruption soon became dry and scaling There is no obtainable history of arsenic ingestion

A diffuse, erythematous, dry, scaling eruption over the extremities and trunk is present There are keratotic lesions on the palms and soles, and keratotic

DR GERALD F MACHACEK It is my impression that a number of the patients that Dr Cannon sent to Texas were persons who handled textiles, and particularly tailors who handled dirty garments

DR GEORGE C ANDREWS My other patient was in Presbyterian Hospital for several months and was seen in consultation by Dr MacKee, who agreed with the diagnosis of chronic discoid and lichenoid dermatosis The eruption cleared up temporarily after electric shock treatments He stayed well for about three weeks and then started worrying, and the eruption recurred He went to a doctor in New Jersey who continued shock treatments and telephoned me that the man was completely cured I said that I would like to hear from him again in about six months Later he told me that the patient was again ill There is certainly a large psychic element in this disease

Knuckle Pads Presented by DR J GARDNER HOPKINS

E M, a married woman aged 40, presents thickening of the skin over the proximal interphalangeal joints of all fingers, but not of the thumbs or toes These have gradually developed over a period of eighteen months There have been no subjective sensations The patient works as a secretary and office nurse There is no history of injury or of rheumatic fever

The lesions form disks 10 to 15 mm in diameter These are firm, inelastic and apparently formed by thickening in the cutis or subcutis without notable epidermal change

Roentgen examination showed no changes in the bones Biopsy showed dense collagen with some evidence of degeneration but no characteristics on which to base a diagnosis

DISCUSSION

DR FRANK C COMBES The only treatment I know of is protective—the lesions should be covered with elastoplast for several months Knuckle pads do not respond well to irradiation

DR MAURICE J COSTELLO This woman has knuckle pads on the second, third and fourth fingers, but none on the thumb I think that if her household activities were carefully studied one could find the cause

DR HOWARD FOX I agree with the diagnosis, but I do not know of any treatment that cures the disease We talk the problem over perennially and get nowhere, except that we agree that none of us has ever seen a case in which it could be proved that trauma was causative

DR RAY H RULISON Some patients have Dupuytren's contracture, which is apparently not a part of the picture and yet it does occur later in some cases

DR GEORGE M LEWIS In a patient with a rather typical lesion temporary improvement was obtained by the use of moleskin adhesive plaster, continuously applied, as first advocated by Kest Moleskin seems more effective than ordinary adhesive plaster

A Case for Diagnosis (Pemphigus Vulgaris? Dermatitis Factitia?) Presented by DR GEORGE C ANDREWS

A Case for Diagnosis (Dermatophytosis? Pustular Psoriasis? Bacterid?) Presented by DR EUGENE F TRAUB

lesions arise from the skin of the body, especially on the shoulders Many pigmented brown macules are present, especially on the back and shoulders

A complete blood cell count showed 4,400,000 red blood cells, 3,800 white blood cells and 13 Gm hemoglobin, with 59 lymphocytes, 7 monocytes, 14 eosinophils, 20 polymorphonuclear leukocytes (mature forms 16 and band forms 4) Blood sodium was 325, potassium 16 25, and cholesterol 185 mg Results of biopsies have not been reported

DISCUSSION

DR HOWARD FOX This man has a striking and profuse pigmentary eruption As the pigment is in the form of small macules and not a diffuse pigmentation, it is certainly not typical of Addison's disease and looks more like arsenical pigmentation Arsenic, however, does not produce pigment in the mouth, whereas Addison's disease does, and there is one small pigmentary patch opposite one of the patient's molars I still think that the whole picture is probably one of arsenical pigmentation

DR PAUL E BECHET There is no dermatologic condition I know of that presents this picture of lentiginous pigmentation, particularly on the shoulder blades The few patients with Addison's disease I have seen show more diffuse pigment, with generalized bronzing The patient does not have the dry skin and furfuraceous scaling so common in arsenical dermatoses

DR RAY H RULISON If this case had been presented as one of arsenical pigmentation and keratosis, with no history of Addison's disease, I think that one would accept it without question However, this case has been carefully studied, and, as I understand it, the patient has never been given arsenic and no excessive arsenic has so far been found If this man has Addison's disease I do not believe that it is fair to say that he must have arsenic retention and that the pigmentary changes are due to that, because they conceivably could be Arsenic should not be part of the diagnosis until it has been demonstrated

DR JOHN C GRAHAM Could the amount of treatment he has had affect his pigment?

DR GERALD F MACHACEK Pigmentary changes in Addison's disease need not be characteristic I saw photographs of patients with Addison's disease that curiously showed leukoderma Dr Potelunas tells me that the patient was admitted to the hospital in a crisis at one time

Eugene F Traub, M D, *President*

George M Lewis, M D, *Secretary*

May 27, 1947

Cavernous Hemangioma (Angioma Venosum Racemosum) Presented by DR MAURICE J COSTELLO

Hairy Nevus of the Scalp Presented by DR FRED WISE

A Case for Diagnosis (Parapsoriasis? Iododerma?) Presented by DR PAUL E BECHET

DISCUSSION

DR ROBERT BARTON, Dubuque, Iowa (by invitation) Since 1946 at the Chicago Intensive Treatment Center 9 patients with granuloma inguinale have been treated with streptomycin In every case the lesions disappeared within forty-five days after treatment was instituted In 3 of the cases there have been relapses Streptomycin as my co-workers and I have used it may or may not cure granuloma inguinale, but to date it is the most effective drug for that disease The pattern in Dr Ebert's case conforms to that in ours After treatment was stopped the lesions continued to heal without additional therapy The patients returned perhaps a month or two later with the lesions completely gone It appears that once treatment is given, the effects are protracted

Werner's Syndrome (Progeria of Adults) Presented by DR T CORNBLEET and (by invitation) DR D COHEN and DR J GRAFFIN

Pigmented Purpuric Lichenoid Dermatitis Presented by DR T CORNBLEET and (by invitation) DR D COHEN and DR N L BAKER

T B, a white man aged 30, has had purplish spots on the legs and dorsum of the feet for two years These are asymptomatic In January 1945 the right testis and epididymis were removed because of tuberculosis

On both legs, mainly on the anterior aspect, there are lichenoid purpuric papules Similar lesions are present on the dorsa of the feet, in groups There are pigmented macules, 2 to 5 mm in diameter, among the papules of the legs and dorsa of the feet

Roentgenogram of the chest reveals a soft fuzzy infiltration in the right apex Biopsy by Dr Caro showed Gougerot-Bloom's disease

DISCUSSION

DR H E MICHELSON, Minneapolis Pautrier said that if we wish to advance dermatology, it would be well if we eliminated ten names a year instead of adding ten new ones Following his suggestion, I would like to eliminate the name Gougerot-Bloom's disease now Sooner or later, we must decide that all of these diseases that are characterized by localized hemosiderosis are one and the same thing and differ only in their extent and their localization Gracing them with long names is one of the troubles that dermatology has had to contend with for many years

Scrofuloderma, Pott's Disease and Retrosternal Abscess Presented by DR T CORNBLEET and (by invitation) DR H SCHORR and DR N L BAKER

A Case for Diagnosis (von Recklinghausen's Disease?) Presented by DR I M FELSHER, DR JULIUS E GINSBERG, DR A SLEPYAN and (by invitation) DR I EIRINBERG

Mrs L P, a well nourished, well developed, Negro woman aged 49, was first seen at Mandel Clinic, Michael Reese Hospital, on May 15, 1947 On the left buttock and left thigh there are present two large, well circumscribed tumors measuring 4 5 by 3 inches (11 by 7 cm) and 7 by 3 inches (18 by 7 cm), respectively These tumors have been present since birth but have caused the patient no difficulty with the exception of occasional discomfort when pressure is applied

The tumors are extremely flaccid, lobulated and pendulous The skin covering them appears lighter and atrophic and at the periphery of the lesions is filled with giant comedos On palpation the lesions are firm and nodular

Microscopic sections taken from the edge and center of the lesion show hyperkeratosis, deep brown pigmentation of the basal layer, flattening of the rete processes and some hyperplastic sebaceous glands containing comedos The corium is replaced by a tumor mass of connective tissue cells containing many small blood vessels There are numerous mast cells present With the Van Gieson stain, the tumor tissue is essentially the same color as that of normal collagen The orcein stain shows absence of elastic fibers throughout the tumor

Lesions on the buttock and thigh of patient with diagnosis of von Recklinghausen's disease

Granuloma Fungoides, D'emblée Presented by DR THEODORE CORNBLEET

F S K, a white man aged 74, presents mushrooming tumors on the right wrist and posterior hair line Near the scalp lesion and on the left ear lobe there are several infiltrated plaques that are sharply outlined and of various sizes There is itching The lesions appeared eight months ago There were no preceding lesions of any kind or any itching The patient was in the hospital about the time of onset of the skin changes

Mycosis Fungoides Treated with Sodium Paraaminobenzoic Acid Presented by DR JAMES H MITCHELL

Mrs L McC, aged 52, was first seen on Jan 18, 1945, with a huge exuding tumor on the left ramus of the jaw There had been a generalized pruritic eruption for the past two years Various lesions of the type on the left cheek had appeared and had healed spontaneously with scarring

A clinical diagnosis of mycosis fungoides was made and confirmed by biopsy Intensive roentgen ray treatment was given to the point of tolerance on various occasions with good immediate response Intramuscular injections of chaulmestrol were begun on Jan 28, 1947, which were followed by an intense generalized toxic eruption

Pustular Psoriasis Presented by DR GEORGE M LEWIS

H J, a white woman aged 36, has had a recurrent pruritic vesiculopustular eruption on the soles for the past five years The pruritus is worse during the menses She was treated for three years with benzoic and salicylic acid (Whitfield's) ointment, aluminum acetate (Burow's) solution and ointment, boric acid and salicylic acid powders, naphthalan, ichthammol, crude coal tar, ammoniated mercury, sulfur, brilliant green, tannic acid, boric acid ointment and roentgenotherapy, with little if any improvement

When I first saw her, two years ago, penicillin ointment was used without success Thereafter for six months she was given intravenous injections of 1 per cent antimony potassium tartrate, supplemented with four fractional doses of roentgen rays and quinolor® ointment (a mixture of three chlorine derivatives of 8-hydroxyquinoline in a base of equal parts of petrolatum and wool fat) This therapy resulted in almost complete involution of the eruption The patient then used chrysarobin ointment and stannoxyl® (a combination of metallic tin and its oxide) tablets There was considerable improvement for several months, with only a few transient vesiculopustules and mild pruritus One year ago another exacerbation occurred Pyorrhea was treated at this time Results of roentgen examination of the teeth were normal The eruption gradually subsided, and the patient was free of lesions until three months ago, when the present relapse began A course of sulfadiazine, 4 Gm daily for two weeks, was given and an ointment containing resorcinol, salicylic acid and chrysarobin was prescribed

An extensive vesiculopustular eruption is present on the palms and soles The lesions are grouped in patches on the soles The nasal and oral cavities are normal, and there are no other evident foci of infection The result of urinalysis was normal, the Wassermann reaction of the blood was negative and cultures were negative for fungi

DISCUSSION

DR EUGENE F TRAUB I have tried antimony potassium tartrate, with the same results Dr Lewis reports temporary slight improvement followed by a return of the eruption I do not believe that it is possible to determine whether the tonsils are actually a focus in a given case even if pus is aspirated from them While it is certainly better to determine in advance that there is an infection in the tonsils, removing infected tonsils does not necessarily cure the eruption In 1 instance in which this was the case I discovered that the patient had an infection in his prostate which was thought to be secondary to the tonsillar infection Improvement followed prostatic massage

DR GEORGE M MACKEE According to histologic work that has been done recently, these conditions can be divided into two varieties One is psoriasis histologically, and the other is not Differentiation may make a therapeutic difference What was said about antimony potassium tartrate therapy is true about every possible treatment for this disease Everything tried has been successful only temporarily, except perhaps removal of foci of infection In spite of the fact that there is no cure, the majority of patients eventually recover

DR HOWARD FOX I agree with the presenter that it is proper to tell the patient, as Dr Andrews does, that it is not certain that he will get well after tonsillectomy, regardless of what organism is found on aspiration I should certainly suggest that this patient have her tonsils removed

Frances M Keddie, M D., *Secretary-Treasurer*

April 26, 1946

A Case for Diagnosis (Thymoma). Presented by DR FRANCES A TORREY

Lymphoblastoma. Presented by DR FRANCES A TORREY

Lupus Erythematosus (Lichen Planus?) Presented by DR HIRAM E MILLER

C F S, a 56 year old white man, was first seen in the Dermatology Clinic of the University of California Hospital on Jan 7, 1946 He gave a history of a reddish scaly dermatitis on the face and neck for the past seventeen or eighteen years and of elevated purplish nodules on the backs of the hands for about one year

The physical examination revealed no abormalities A blood cell count and urine were reported normal The Kolmer and Kahn reactions were negative A fairly symmetric erythematous and scaly eruption involves the ears, nose and sides of the neck Whitish retiform lesions are present on the buccal mucosae, and the lips showed some deformity from atrophic scarring On the dorsa of the hands are groups of large, elevated, flat-topped and rounded violaceous papules

Biopsy specimens were obtained from the dorsum of the left hand and from the side of the neck Studies of a section from the neck showed slight parakeratosis and relative acanthosis The granular layer was prominent, and the basal cell layer of the rete pegs showed some liquefaction degeneration A fairly dense round cell infiltrate was present and was confined to the papillae and upper part of the cutis

The section from the dorsum of the hand showed prominent hyperkeratosis and an increased granular layer There were decided acanthosis with some liquefaction degeneration of the basal cell layer A moderately dense round cell infiltrate was present in the papillae and upper part of the cutis

Bismuth subsalicylate was given, 0 2 Gm intramuscularly weekly for a total of sixteen injections During this period there has been gradual regression of all cutaneous lesions

DISCUSSION

DR ERVIN EPSTEIN I had the opportunity of seeing this patient ten years ago in Los Angeles At that time he had typical lupus erythematosus on the nose and lips and no other lesions

DR. F G NOVY JR I agree with the diagnosis of lupus erythematosus

DR REES B REES I think that someone should point out the remarkable bandlike infiltrate in the sections from the hand and neck and the prominent

Psoriasis Following Smallpox Vaccination in a Seven Year Old Boy Presented by DR GEORGE M LEWIS

A Case for Diagnosis (Ulcus Vulvae Acutum of Lipschutz?) Presented by DR ANTHONY C CIPOLLARO

T L, a woman aged 35, first consulted me on Nov 15, 1946, because of recurrent ulcerative vulvar and oral lesions of eighteen months' duration The lesions began as small blisters and soon ulcerated The patient has used a number of remedies, but the lesions have continued to recur A month before consulting me the patient went to the Lahey Clinic for a complete medical check-up Her general physical examination was entirely normal except for slight obesity and the lesions of the mucous membranes of the mouth and vulva The result of the Hinton test was negative, and all laboratory studies gave normal results A smear from the vagina contained a moderate number of gram-negative bacilli, a few gram-positive bacilli and extracellular gram-negative diplococci No intracellular gram-negative diplococci were seen Smears from the mouth showed a moderate number of fusiform bacilli and gram-negative bacilli There were also a few gram-negative diplococci A positive diagnosis was not made, but the following diagnoses were considered Vincent's angina, aphthous stomatitis, Behcet's triple symptom complex, erythema multiforme, dermatitis herpetiformis and pemphigus

When I first saw the patient she had discrete pinhead-sized to pea-sized, deep, ulcerative lesions on the mucous membrane of the labia minora and some in the posterior part of the fourchet The mucous membrane surrounding and underlying the lesions was painful, red and somewhat edematous A few ulcerative lesions, much smaller and less severe, were seen in the mouth, and the gums appeared to be inflamed The tongue and the roof and floor of the mouth were essentially normal On clinical grounds the diagnosis of ulcus vulvae acutum was made There was no biopsy

The patient was treated with antiseptic solution, penicillin ointment and acetarsone and showed quick response There has been a recent exacerbation of the gums, and the patient was given vitamin C and riboflavin

She is presented for diagnosis and for suggestions regarding therapy

DISCUSSION

DR. A BENSON CANNON I suspect that the case is one of pemphigus Pemphigus sometimes remains limited to the mucous membranes for many months, and it is difficult to diagnose before it becomes generalized For example, a patient was admitted to the Vanderbilt Clinic several months ago with a severe, widespread, bullous eruption, conjunctivitis and lesions in the mouth and pharynx and on the labia, and a diagnosis of bullous erythema multiforme of the Stevens-Johnson type was made She now has typical pemphigus vulgaris with vegetating lesions Dr Cipollaro's patient is similar to the one I presented this afternoon The lack of pain and the number of lesions are against the diagnosis of ulcus vulvae acutum

DR FRED WISE It is difficult to make a definite diagnosis in cases of this kind, unless one has the opportunity of keeping the patient under observation for a long time Patients with a diagnosis of ulcus vulvae acutum sometimes have

follicular plugging in the epidermis There are some plasma cells in addition to small round cells

DR HARRY J TEMPLETON The lesions on his hands are deep violaceous and are thickened They are classic lesions of lichen planus hypertrophicus There may be two conditions

DR NORMAN EPSTEIN It is of interest that biopsy specimens from the hands and neck in this case are much alike Although the bandlike infiltrate in the upper part of the corium suggests lichen planus, the lesions on the face could hardly be anything but lupus erythematosus

DR ARNE E INGELS I agree, the sections verify that

DR HIRAM E MILLER I examined sections from this patient and made a diagnosis of lichen planus, but after examining the patient I feel reasonably certain that he does not have this disease The microscopic observation must be correlated with the clinical picture The patient certainly has lupus erythematosus on the face, and the lesions on the dorsa of the hands resemble lichen planus but could be, and probably are, lupus erythematosus The sections showed an increase in the granular layer, and the infiltrate was certainly bandlike The histologic changes are compatible with the diagnosis of lupus erythematosus, and the clinical appearance, I think, is also that of lupus erythematosus

A Case for Diagnosis (Necrotic Nodules on the Face?) Presented by DR ERVIN EPSTEIN

DISCUSSION

DR G V KULCHAR The diagnosis for the older woman of the 2 patients, I think, is factitious dermatitis, which is especially apparent from the linear scarring The disease of the other woman might be what is called pyoderma faciale

DR REES B REES I believe that both women have neurotic excoriations The case that Dr Kulchar discussed first is interesting and classic, because of the patient's elaborate description of the manipulation of her lesions

DR MERLIN T-R MAYNARD, San Jose, Calif I agree with the diagnosis of neurotic excoriations Both women admit picking and squeezing their skin The scars are typical of those produced by persistent manipulation I tried the pharyngeal reflexes in each of them Each has a rather active pharyngeal reflex

DR. ERVIN EPSTEIN The diagnosis of dermatitis factitia presupposes a method of producing the lesions These lesions started subcutaneously as hard nodules There is no question that the lesions have been altered mechanically, but I still find it difficult to believe that the lesions could be produced by any chemical, physical or mechanical agent

DR E J RINGROSE (by invitation) I think that these excoriations were produced by finger nails I believe that one should differentiate between neurotic excoriations, of which the lesions in these cases are typical, and dermatitis factitia produced by chemical or other destructive agents Have you not seen a primary lesion produced by pinching and squeezing?

DR E K STRATTON I think that these patients can be helped by a psychiatrist if they wish to be helped However, most of them are not willing to cooperate I believe that in any event they belong in the office of a psychiatrist and not in the office of a dermatologist

remissions and exacerbations over a period of several years, and the condition is resistant to therapy

DR EUGENE F TRAUB Does the patient take aminopyrine?

DR ANTHONY C CIPOLLARO She does not take any medicine A culture for Monilia was made at the Lahey clinic, and it was negative I considered pemphigus, as did some of the men at the Lahey Clinic, but thus far she has had no more manifestations than she showed tonight I shall have to observe her further

Multiple Vaccination of the Face (from Barber Shop?) Presented by DR EUGENE F TRAUB

G R, a man aged 68, was first seen May 7, 1947, complaining of an eruption of eight days' duration He had not been vaccinated but had been shaved by a barber twice weekly prior to the appearance of the eruption It was not determined whether the barber had been vaccinated or whether he had had recent contacts which might have resulted in the vaccination of the patient An adult son had been vaccinated but lived separately from the father, and little or no contact had occurred between them preceding the infection The probability is strong that the vaccination occurred in the barber shop

The patient's appearance was striking, as all lesions were located in the bearded area There were at least thirteen lesions, but several on the right side of the chin had become confluent, so that there was now one huge, inflamed and necrotic mass Most of the other lesions had remained discrete and were present on the left side of the chin and on both cheeks All had the appearance of strong vaccination "takes," and consisted of inflamed bases with pustular and necrotic centers Some were slightly crusted Healing was uneventful, and most of the lesions, including even the large confluent one, had disappeared completely in ten to fourteen days Deep scarring marks the site of the confluent area, but the remaining lesions have left only superficial redness, which may disappear entirely

DISCUSSION

DR HOWARD FOX I think that it is possible that the patient acquired the vaccinia in the barber shop A number of years ago I was lecturing at New York University on eczema and mentioned that one of the dangerous sequelae was vaccinia, saying that no child with eczema should be vaccinated While lecturing I got a note from the pediatric department asking me to come to Bellevue Hospital to see a child The child was a 2 year old Negro with typical lesions of vaccinia on a large part of the body, which he had contracted from an older sister who had recently been vaccinated He died in about six days

DR ANTHONY C CIPOLLARO The thought came to me that these sequelae might be prevented by covering vaccinations Patients rub and scratch and reinoculate, and for this reason I have covered vaccinations in members of my family and in my own case I think that it prevents this sort of accidental vaccinia

DR EUGENE F TRAUB I thought that I had fairly well excluded all sources of inoculation but the barber shop The only other member of the family who had been vaccinated was an adult son, who did not use the same bathroom as his father

Sarcoidosis in a Negro Woman Aged 33 Years Presented by DR. A BENSON CANNON

DR HIRAM E MILLER In general, I believe that these patients will be seen by the psychiatrist for a visit or two, and then they will come back to the dermatologist If their delusions are well established, little can be done for them by the psychiatrist or the dermatologist

DR E J RINGROSE (by invitation) Favorable results have been achieved with patients with dermatitis factitia who would submit themselves to interview Most of the patients, under the influence of sodium amytal® (sodium isoamylethylbarbiturate) given intravenously, will admit what they have been using

DR MERLIN T-R MAYNARD, San Jose, Calif One of the patients admitted the use of needles and pincers Her euphoric personality fits into the diagnosis readily The other one started talking about herself and her troubles immediately, which fits into the picture of a neurosis of the neurotic excoriation type, a typical picture Nodules particularly can be produced by a traumatic agent We all see children pick and squeeze their skin, but it does not result in hemorrhage into the areas

DR ERVIN EPSTEIN I realize that the condition in such cases is usually diagnosed as dermatitis factitia, and I am willing to accept that diagnosis for these patients However, I am unable to see how the primary subcutaneous nodules could be produced mechanically

A Case for Diagnosis (Bacteremia?) Presented by DR FRANCES A TORREY

A Case for Diagnosis (Dermatitis Medicamentosa?) (Purpura Annularis Telangiectodes?) Presented by DR FRANCES M KEDDIE

V D C, a 47 year old Portuguese woman, was first seen in the University of California Dermatology Clinic in March 1945, at which time a diagnosis of black hairy tongue was made No cutaneous eruption was present at that time

On April 1, 1946, she returned to the clinic because of lesions of both legs of about ten months' duration There are numerous pigmented purpuric macules of various sizes and shapes Many of these lesions show telangiectasia The patient states that she had taken "sleeping pills" regularly for many years The physical examination revealed no abnormalities

Laboratory examination revealed 4,400,000 erythrocytes, 90 per cent hemoglobin and 8,900 leukocytes, the differential count was normal The sedimentation rate was 11 mm in 1 hour The capillary clotting time was 8 minutes The tourniquet test at a pressure of 80 mm of mercury for 15 minutes caused numerous petechiae The prothrombin time was 80 per cent The urine was normal

Microscopic sections showed increased deposition of pigment in the basal cell layer and occasional deposits of hemosiderin in the cutis Extravasation of red blood cells and hyalinization of several vessel walls were noted A perivascular infiltrate consisting of lymphocytes and polymorphonuclear leukocytes was present

DISCUSSION

DR NORMAN EPSTEIN This case suggests Majocchi's disease

DR STUART WAY A diagnosis of dermatitis medicamentosa is in order, but not Majocchi's disease This case has none of the characteristics of purpura annularis telangiectodes in the cases that I have reported

DR HIRAM E MILLER This is a good example of purpura, but not of purpura annularis telangiectodes There is no definite annular appearance, and there are no telangiectases It may be a toxic purpura, but not Majocchi's disease

A Case for Diagnosis (Lichen Planus? Lupus Erythematosus?) Presented by Dr Maurice J Costello

Hereditary Hemorrhagic Telangiectasia with Hemangioma Presented by Dr John N Graham

A Case for Diagnosis (Lichen Planus Hypertrophicus? Amyloidosis?) Presented by Dr Anthony C Cipollaro

Psoriasis Exacerbation Following Vaccination Presented by Dr George M Lewis

B O, a woman aged 23 from New York Hospital, has had psoriasis since the age of 6, limited to the elbows, scalp and sacral region, with mild exacerbations and remissions Five weeks ago she was vaccinated, and three days later numerous small psoriasiform lesions developed on the trunk, face, neck and extremities A confluent nummular patch of psoriasiform lesions appeared at the vaccination site, and the long-standing patches on the elbows and scalp became larger One sister also has psoriasis

There are numerous dime-sized to quarter-sized erythematous scales distributed over the face, neck, trunk and extremities The vaccination area shows a dollar-sized psoriasiform patch The Mazzini reaction of the blood was negative The results of biopsy were compatible with acute psoriasis

DISCUSSION

Dr George M Lewis This is the third patient we have seen with an acute attack of psoriasis developing immediately after vaccination Since the cause of psoriasis is not known, one could consider that in some way the virus infection had had a specific effect on the disease

Lichenoid Miliary Sarcoid Presented by Dr Maurice J Costello

A Case for Diagnosis (Pemphigus?) Presented by Dr A Benson Cannon

Vaccinia, Generalized, Following Vaccination for Smallpox Presented by Dr A Benson Cannon

Leprosy, Lepromatous Type, with Tufted Destruction of the Tips of the Terminal Phalanges Presented by Dr Maurice J Costello

B O, a man aged 20, a Puerto Rican, is presented from Willard Parker Hospital, to which he was transferred from Harlem Hospital He had sought attention at the latter institution on March 13, 1947, because of pain in the right groin, severe nausea and vomiting Intestinal obstruction was considered on admission, but the gastrointestinal symptoms subsided with conservative treatment

While the patient was in Harlem Hospital, a cutaneous eruption was noted, although his skin was reported to have been clear on admission He had noted scaling of the feet in October 1946 No one in the family has a similar eruption and there has been no known contact with leprosy The patient has been in the United States for about eight months

DR FRANCES M KEDDIE When the patient was first seen the lesions were annular and telangiectatic, now they are purpuric and diffuse Tonight she stated that she had been taking "sleeping pills" for one year only This eruption is certainly of not more than one year's duration and may be a toxic reaction to self medication

Dissecting Cellulitis of the Scalp (Perifolliculitis Capitis Abscedens et Suffodiens) Presented by DR GRANT MORROW

A Case for Diagnosis (Psoriasiform Eruption? Lymphoblastoma?) Presented by DR FRANCES A TORREY

A Case for Diagnosis (Keratosis Palmaris et Plantaris Associated with Carotenemia? Pityriasis Rubra Pilaris?) Presented by DR H V ALLINGTON

Hodgkin's Disease and Cutaneous Torulosis Presented by DR FRANCES A TORREY (previously presented by DR TORREY at the April 1945 and October 1945 meetings of the San Francisco Dermatological Society)

A Case for Diagnosis (Localized Scleroderma?) Presented by DR NORMAN EPSTEIN and DR. JULES KEY (by invitation)

A Case for Diagnosis (Melanosis of Riehl?) Presented by DR H V ALLINGTON

V G, a white woman aged 46, was seen first on April 11, 1946 She presented a brownish pigmentation of the face, the neck, the exposed portion of the upper part of the chest and to a lesser degree of the arms The skin also showed irregular telangiectasia and erythema and on the cheeks was shiny and glazed The patient stated that this condition had been present a little over two years

The patient attributed this to exposure to the fumes from hot lubricating oils in her work for an oil company Her work consisted in running viscosity tests and gaging tanks of hot oil She had done this work for about four years She stated that exposure to the fumes from the hot oil caused her skin to burn and sting and become "purplish pink" After work, cool applications were required to quiet the burning sensation Recently she used vinegar for relief She had not done anything previously about her problem because she was anxious to hold her job, which she liked She had also noticed that exposure to sunlight caused increased redness, burning and stinging However, her work was indoors, and exposure to light was kept at a minimum She further stated that exposure to the fumes of heavy oils was more irritating than to that of light oils

She is for the most part a vegetarian She does not eat carrots or other carotene-containing foods to excess, however, and the character of her pigmentation is not that of carotenemia

I believe that this patient is one who is sensitive to the fumes from hot oils and that her reaction is primarily on this basis An endocrine or dietary deficiency may be present and may increase the sensitivity of her skin

DISCUSSION

DR HARRY J TEMPLETON I saw this patient with Dr Allington, and at that time there was a question of industrial liability The patient has some

Biopsy at Harlem Hospital showed cutaneous nodular leprosy

Roentgen examinations at Willard Parker Hospital showed destruction of the tufted ends of all terminal phalanges of the fingers and toes There was periostitis of the proximal phalanges of all four fingers of the right hand

Results of roentgenographic examination of the chest were normal, ruling out sarcoid The Kline reaction of the blood was 4 plus, and the Mazzini reaction was negative Determinations of the chemical content of the blood showed a reversal of the albumin-globulin ratio, the albumin being 2 Gm and the globulin 6 Gm A blood cell count revealed 4,260,000 red blood cells and 11,500 white blood cells, with 65 per cent polymorphonuclear leukocytes, 24 per cent lymphocytes, 7 per cent eosinophils and 3 per cent large mononuclear cells The urine was repeatedly normal A nasal smear showed lepra bacilli

DISCUSSION

DR HOWARD FOX The man who made the original diagnosis, probably Dr Irgang at Harlem Hospital, is entitled to much credit The patient comes from a country where leprosy is endemic, but one must examine him carefully to discover any changes The ulnar nerves are unquestionably enlarged all the way to the axillas, and one may press on them hard without causing any pain, which is much in favor of leprosy There are nodules on the ear and some enlargement of the great auricular nerve, although there is no anesthesia In a recent article Arnold expressed the belief that examination of the nasal smear for lepra bacilli is of little diagnostic help It is not the best way to prove a diagnosis of leprosy The radiologic changes in the phalanges in this case are significant

George M Lewis, M D, *President*

John C Graham, M D, *Secretary*

Nov 25, 1947

Lichen Planus Limited to the Oral Mucosa Presented by DR GEORGE M LEWIS

E S, an American lawyer aged 43, discovered an asymptomatic white lesion on his tongue eleven months ago Six months later he saw his physician and then an oncologist, both of whom made a diagnosis of leukoplakia

The patient smoked two pipes and fifteen cigarets daily, used magnesia magma as a mouthwash and a magnesia magma tooth paste He took a "vitamin pill" daily and a "sleeping pill" every two weeks In June 1947, when I first saw him, there was a bluish white lesion on the dorsum of the tongue about 2 by 1 cm in extent, an area similar in appearance was present inside the cheek opposite the lower right molars A circinate lesion was found near the oral commissure on the buccal mucosa of the left cheek

The patient has not smoked since June He is using a bland mouthwash Partial involution of the lingual lesion has occurred, but those on the buccal mucosa have remained unchanged

DISCUSSION

DR HOWARD FOX It is sometimes difficult to differentiate between leukoplakia and lichen planus, but as Dr Combes said, leukoplakia tends to be thickened and rough and even verrucous, which lichen planus does not Without biopsy, it is difficult to tell in some cases I think that this patient probably has lichen planus

sort of poikiloderma I do not know whether it is melanosis of Riehl or poikiloderma of Civatte or whether it is primarily an abnormal reaction to light and to tar and oil I think that Dr Fasal is able to tell us more about melanosis of Riehl since he worked in the Riehl clinic, with both the elder and the younger Riehl

DR PAUL FASAL I think that this is a case of melanosis, but not melanosis of Riehl Riehl included in his description only cases due to ingestion of toxic products Those cases were seen after World War I when people used various food substitutes containing toxic products I consider this disease a tar melanosis, but not melanosis of Riehl

DR F G NOVY JR In a generalized Berloque dermatitis there is the same problem of perfumes plus sunlight This woman is probably a sensitive person who has been exposed to various tar products and sunlight and has reacted with the formation of pigment

DR HIRAM E MILLER I agree with Dr Fasal It is melanosis, but not melanosis of Riehl or poikiloderma Dr Templeton made the statement that he thought it was melanosis of Riehl or poikiloderma and that there was a question of industrial liability I believe that if either of these two diagnoses were accepted, there would be no question about industrial responsibility The distribution of lesions here is not that of melanosis of Riehl, because, as I understand it, the scalp is always involved in this disease In this patient the scalp is not involved The patient has no involvement around the breasts and in the axillary folds as is usually observed Melanosis of Riehl is of toxic origin, while in this patient the causative factor is tar and oil plus sunlight For these reasons I believe that it is melanosis, but not melanosis of Riehl

DR HARRY J TEMPLETON I agree with Dr Novy that this is due to action of tar or oil on skin which has become sensitized to sunlight

DR REES B REES According to the textbooks, in tar melanosis the distribution is confined to face, scalp, shin, hands and forearms There is pigmentation, but telangiectasia or atrophy is not mentioned The patient has telangiectasia

DR MERLIN T-R MAYNARD, San Jose, Calif The fact that the patient is a machine operator should be considered Hot tars and oils become volatile Considering the fact that tar could have been ingested through three channels, the skin, the respiratory tract or the mouth, it is possible that she has ingested a certain amount of it through the respiratory system The traps of respirators demonstrate that one eats what one breathes This could therefore be melanosis of Riehl in the classic sense

ERVIN EPSTEIN, M D, *President*
FRANCES M KEDDIE, M D, *Secretary-Treasurer*
Sept 13, 1946

Pemphigus of the Conjunctiva Arsenical Pigmentation and Keratoses from Fowler's Solution. Presented by DR OTTO E L SCHMIDT

Angiokeratoma? Presented by DR OTTO E L SCHMIDT

Subcutaneous Granuloma Annulare Presented by DR HIRAM E MILLER

T H S, a four year old white boy, was first seen in the University of California Hospital on July 9, 1946, with a chief complaint of multiple nodules

DR ANTHONY C CIPOLLARO I agree with the presenting diagnosis I think that too often patients with leukoplakia are given a serious prognosis Carcinoma does develop in patches of leukoplakia, but it is of rather infrequent occurrence, and people interested in the cancer problem lead us to believe there must be a definite sequence from leukoplakia into cancer, which *I think is erroneous* I recently saw a physician with extensive lichen planus all over the body, with extensive lesions on the buccal mucosa, including the border of the lip, and on the vocal cords, causing him to be hoarse They could be seen distinctly with the laryngeal mirror I have never seen or read of lesions of lichen planus on the vocal cords

DR GEORGE C ANDREWS I think that fear of leukoplakia is well warranted by the fact that often when it does become cancerous the lesion is extremely serious and by the fact that one never knows in a case of leukoplakia whether cancer cells are present or not One may take a biopsy specimen from one portion of the leukoplakia and histologically find only leukoplakia and then cut some more sections and find cancer So it is a serious disease, and I believe that lichen planus of the mouth is also a serious disease, especially if it lasts over some time I have had 2 patients with lichen planus of the buccal mucosa in whom cancer of the buccal mucosa developed after the lesions had been present for twenty years It is certainly a precancerous disease I do not think that the fact that this man has lichen planus means that he has nothing to worry about The patient should be treated and should be watched, told to stop smoking and given vitamin B complex and whatever other therapy may be available

DR JOHN C GRAHAM I agree with the diagnosis It seems to me that the lesion on the tongue was rather typical of a healing lichen planus

DR HOWARD FOX I had occasion to write up a series of 10 cases of lichen planus confined to the mouth One of the patients, a man whom Dr Udo Wile had seen, was a great smoker and for eight years had had attacks of lichen planus that flared up after smoking, when he stopped smoking the eruption quieted down

DR GEORGE M LEWIS I believe, as Dr Andrews does, that a patient with lichen planus of the buccal mucosa should stop smoking, and the patient was so advised He was given a bland mouthwash but no other treatment because my results have been rather poor in treating lichen planus of the buccal mucosa

Edema Due to Hypoproteinemia Presented by DR FRANK C COMBES

D E, a white girl aged 16, was admitted to Bellevue Hospital complaining of long-standing swelling of both legs It was noted a few days after birth, but it was not known whether it was confined to the legs The patient states that the swelling disappeared spontaneously from the age of 2 years until she was 8 When at the age of 9 or 10 years the swelling recurred, she entered Mount Sinai Hospital, where extensive studies were done and reported (Schick, B, and Greenbaum, J W Edema with Hypoproteinemia Due to Congenital Defect in Protein Formation [Case Report], *J Pediat* **27** 241-245 [Sept] 1945) After her discharge the swelling of the legs remained stationary with no accompanying fever, inflammation or tenderness In 1946 she reentered Mount Sinai Hospital twice, blood plasma transfusions were given with but temporary relief, the swelling would go down for two days and then recur Her most recent admission to Mount Sinai Hospital took place in the summer of 1947 At that time, in addition to the usual swelling of the extremities, there was edema of the face, back and abdomen She was treated with sodium and potassium acetate, as a result of which the condition of all but the legs returned to normal The edema of the legs has persisted

on the legs and back of the head of about eight months' duration A history of a fall prior to their appearance was obtained, but subsequently more nodules developed without preceding trauma

Positive physical observations include nontender firm fixed nodules on the left occipital region, larger purplish nodules on the right tibia and similar smaller nodules on the left knee There is generalized nontender moderate adenopathy Routine tests revealed that the blood and urine were normal The reaction to an intracutaneous tuberculin test, in dilution of 1 1,000, was negative The reaction to the coccidioidin test, in dilution of 1 1,000, was negative The blood cholesterol was 112 mg per hundred cubic centimeters Serum protein was 6 mg per hundred cubic centimeters (albumin 3 8 Gm and globulin 2 2 Gm) Serum calcium was 12 mg and serum phosphorus 4 48 mg per hundred cubic centimeters Phosphatase was 6 2 Bodansky units Roentgenograms of the chest and long bones showed no abnormalities Biopsy of the marrow revealed a normal differential count Microscopically the sections of a nodule showed a focus of coagulation necrosis of the connective tissue surrounded by radiating strands of fibroblasts, epithelioid cells and lymphocytes in palisade arrangement (Starting Aug 20, 1946, both cutaneous lesions were irradiated, a total of 200 roentgen rays was used with a 3 mm filtration of aluminum)

DISCUSSION

DR REES B REES I saw this patient on the ward with Dr Miller, Dr Keddie and other members of the staff At that time we thought of sarcoid, having just the clinical appearance to go on The lesion on the left knee was clinically suggestive of granuloma annulare, but we did not think of that diagnosis until the histologic section was studied Dr Brown found an interesting article by Udo Wile on this subject

DR MARSHALL BROWN (by invitation) This article appeared in the ARCHIVES OF DERMATOLOGY AND SYPHILOLOGY (**30** 785, 1934), a report of an unusual case of granuloma annulare by Dr F G Graver and Dr Udo Wile, of the University of Michigan Medical School The first reports were in 1908 by a British writer, Dr Graham Little He reported several cases of possible subcutaneous granuloma annulare The next reports were written in 1931 by Jacobi (Jadassohn, J Handbuch der Haut- u Geschlectskrankheiten, Berlin, Julius Springer, 1931, vol 10, p 796) He reported several cases of subcutaneous granuloma annulare which occurred on the palms and the flexor surfaces of the fingers, and the dorsal surfaces of the feet and lower extremities However, there were no case reports at that time of subcutaneous granuloma annulare occurring in the scalp The case reported by Dr Wile occurred in a 2 year old white boy who was admitted to the hospital with a history of subcutaneous nodules on the scalp, the flexor surface of the left wrist and the extensor surface of the right tibia Our patient's mother stated that the first time she noted nodules on the flexor surface of the wrist was five months prior to the patient's entrance into the hospital Three months before admission she noted five nodules occurring in the subcutaneous tissues of the scalp, and two months before admission she noted nodules occurring on the extensor surface of the right tibia Physical examination revealed subcutaneous nodules which were firm and attached to the underlying tissue, and the overlying skin was loose and movable There was no previous history of tuberculosis Members of the family were examined for tuberculosis, no evidence of this disease was found In the hospital the patient was asymptomatic

DR E K STRATTON Have a tuberculin test and guinea pig inoculation been done?

unchanged up to the present On elevation of the feet, the edema shifts to the thighs and abdomen Hematologic studies at Mount Sinai Hospital showed essentially normal conditions except for hypoproteinemia The report of protein fractionation revealed reduction of all protein fractions, with complete absence of gamma globulin

Studies at Bellevue Hospital showed a total protein content of 5 2 Gm with albumin 2 6 Gm and globulin 2 6 Gm The cephalin-cholesterol flocculation reaction was negative On another occasion the total protein was 4 5 Gm (albumin 3 3 Gm and globulin 1 2 Gm)

Examination shows both thighs and legs to be indurated with a noninflammatory type of edema which pits on deep pressure The enlargement of the left is the greater of the two The skin of both legs shows slight thickening, with a little pigmentation and a few nodular infiltrations There appear to be constricting bands around the ankles There is slight pitting edema of the dorsa of both hands The face, especially around the malar bones, seems slightly puffy Some reduction of the swelling of the legs is noted on elevation

DISCUSSION

DR GEORGE C ANDREWS I am pleased to have seen this case because I have a patient with similar swelling of the legs of unexplained cause, but a study of the serum proteins has never been made It is interesting to me that this condition of the serum globulin exists I did not realize that people live without gamma globulin What was the interval in dates between the globulin determinations?

DR GERALD F MACHACEK Dr Combes noted a discrepancy in the determinations in different institutions

DR MAURICE J COSTELLO If one did not know the history of absence of serum globulin, one would almost think this patient had Milroy's disease She has lymphangiectases and fibrous nodules on the anterior tibial regions She had her first attack of erysipelas of the leg while she was in the hospital She has been quite free of infections of all types, I asked her whether she had ever had measles, and some one said her brother had the disease but the patient was given gamma globulin in the incubation stage and acquired measles in a mild form

DR GEORGE M LEWIS Will Dr Combes please outline the difference between this condition and Milroy's disease?

DR MAURICE J COSTELLO Apparently this patient's symptoms have remained exactly the same through the years, so one would not expect much change in the globulin estimations You will recall a case that I presented last year for Dr Wise, that of the baby of a physician who presented an unusual generalized edema not unlike that shown by this patient I shall advise the father regarding this case and suggest determinations of the gamma globulin

Sclerodactylia (?) Following Myocardial Infarction Presented by DR GERALD F MACHACEK

DISCUSSION

DR GERALD F MACHACEK I ran across an article by A H C Johnson in the *Annals of Medicine* (**19** 433-456, 1943) reporting a series of 178 consecutive cases of myocardial infarction, in 21 8 per cent of which the patient evidently presented this type of lesion In the same volume Kenneth C Kehl (pp 213-223) reported 6 cases of Dupuytren's contracture in the presence of myocardial infarction

DR REES B REES A guinea pig inoculation was done at the Permanente Hospital, but the result was not reported to us Necrobiosis lipoidica diabeticorum resembles this disease histologically, but the comparison ends there

A Case for Diagnosis (Actinic Dermatitis? Lupus Erythematosus?) Presented by DR REES B REES

Carotenemia Presented by DR H V ALLINGTON

A Case for Diagnosis (Monilethrix?) Presented by DR H V ALLINGTON

Generalized Progressive Scleroderma Presented by DR WILLARD M MEININGER

A Case for Diagnosis (Progeria? Lupus Erythematosus?) Presented by DR FRANCES M KEDDIE

D A B, a 6 year old white girl, was first seen in the University of California Dermatology Clinic on Aug 12, 1946 Dermatitis has been present on the face since the age of 6 months One year ago she sustained second degree burns of her arms and back which required skin grafting In the pediatric clinic a diagnosis of microcephaly, dwarfism and congenital heart disease was made

At the present time there is a rather diffuse blotchy erythematous scaly eruption with scarring and atrophy involving the nose and cheeks There are numerous, discrete, erythematous, papular and excoriated lesions on the extremities The lids are reddened and crusted and the conjunctivas injected Her height, weight and skeletal measurements are below normal for her age

There were no abnormal observations in laboratory studies of the blood, urine, glucose tolerance and urine porphyrins The tuberculin cutaneous reaction was negative

DISCUSSION

DR HARRY J TEMPLETON I presented the same patient with the same diagnosis at one of our previous meetings My co-workers and I have studied this case at the Children's Hospital in Oakland and wound up just where we started Not only was there some abnormal delay in the general development of the child, but of the skull, the heart and the child's skin, and for lack of a better classification it was called progeria I cannot say that the lesions have made much progress or retrogression, they are still in status quo The child is not microcephalic, she is rather bright for her age

DR W F HARDING (by invitation) We do not feel that this disease quite fits into the picture of progeria The child does not show atrophic changes in the skin She has no loss or graying of hair or arteriosclerosis Talbot of Harvard has studied a number of cases of progeria The results of all metabolic studies made in these cases were within relatively normal limits Talbot and his co-workers came to the conclusion that in cases studied the caloric intake and output was more or less in equilibrium, all the heat and energy being expended without anything being left over for body development Most patients showed greatly increased metabolism without hyperthyroidism

This patient seems to be acquiring that condition as well It could be explained on the basis of anoxemia Going into the possibility of whether the condition was due to the coronary sclerosis, Johnson came to the conclusion that it probably is a cardiac pain reflex because of the peculiar connection between the first thoracic segment and the lower cervical and upper thoracic sympathetic ganglions, causing reflex constriction of the vessels of the hands "Trophic" ulcers of the hands following coronary disease also occur

A Case for Diagnosis (Bullous Lupus Erythematosus?) Presented by DR MAURICE J COSTELLO

A Case for Diagnosis (Dermatitis Medicamentosa? Mycosis Fungoides?). Presented by DR HOWARD FOX

Epidermal Cyst on the Finger Presented by DR MAURICE J COSTELLO

Dec 16, 1947

Acnitis Presented by DR A BENSON CANNON

A Case for Diagnosis (Ulcus Vulvae Acutum? Triple Symptom Complex of Behcet?) Presented by DR A BENSON CANNON

Chronic Lymphedema of the Face, Hypertrophic Gingivitis, Rosacea Presented by DR ANTHONY C CIPOLLARO

A S, a woman aged 45, first noticed swelling of the upper lip, nose and right side of the face eleven years ago, with less involvement of the left side of the face These episodes of swelling were thought to be due to some infection of the teeth, but multiple extractions yielded no improvement The patient suffered an attack of Bell's palsy on the right side about ten years ago, accompanied with a severe exacerbation of the facial swelling on the affected side, and this has continued more or less unabated up to the present The condition is greatly aggravated by exposure to cold or dampness

The patient presents a nonpitting, moderately firm, edematous swelling of the cheeks, nose and right periorbital tissues The right side of the face shows the greater involvement In addition, there is a papular eruption of the nose and cheeks with moderate erythema of the affected areas The gingivae are greatly swollen

DISCUSSION

DR RAY H RULISON I have never seen that type of gingivitis The patient said that her dentist had taken roentgenograms of those teeth and found them perfectly sound I thought that the swelling of the gum was related to the lymphedema

Adenoma Sebaceum Multiple Sebaceous Cysts with Hypertrophy and Hyperplasia of Sebaceous Glands Presented by DR JOHN M GRAVES

A Case for Diagnosis (Pemphigus Vegetans?) Presented by LIEUTENANT COLONEL ROBERT S HIGDON, Medical Corps United States Army, Letterman General Hospital, San Francisco (by invitation)

J R, aged 34, while stationed in Tokyo, noticed slight intermittent epistaxis on April 15, 1946 Examination revealed a pinhead-sized creamy white papule ½ inch (1 27 cm) within the right nares on the lateral wall The papule grew rapidly and, within one week, had reached the size of a bean and was verrucous in appearance Within two weeks continued growth caused partial obstruction of the right nares At this time a second whitish pinhead-sized papule was noted just inside the left nares on the medial wall He was given treatment with sulfonamide drugs By the third week, the right nares was completely occluded and the second lesion had grown so rapidly that the left nares was partially occluded He was admitted to the 42d General Hospital in Tokyo, on May 6 Treatment with sulfonamide drugs was discontinued The verrucous growths were removed from both nares with electric cautery Within a week the lesions reappeared, accompanied with signs of secondary infection Results of dark field examination, biopsy, smears, cultures and serologic and blood tests were negative The lesions rapidly regenerated, completely obstructing both nares, and extended externally to involve all surfaces of the lower portion of the nose for a distance of 1 cm The patient was given one hundred and nine intramuscular injections of penicillin (40,000 units each) for a total of 4,360,000 units While he was receiving penicillin, three new papules developed, one on the central portion of the upper lip and one on each lateral aspect of the chin These papules grew rapidly until they reached a diameter of 2 cm, were verrucous in appearance and exuded a clear serous fluid All laboratory work (including biopsy) was repeated, but results were again negative The patient was evacuated to the United States by plane and admitted to Letterman General Hospital on July 26 Smears, cultures, animal inoculation, biopsy, serologic and blood examinations, urinalysis and roentgenograms of the chest have revealed no abnormalities The lesions continued to spread and have gradually involved the entire chin, lower lip and midportion of the upper lip Three weeks ago the mucosa over the soft palate, uvula, pharynx and tonsillar areas became erythematous, causing some pain on deglutition Topical applications have consisted of boric acid, benzalkonium chloride and penicillin and bichloride of mercury compresses Penicillin in oil (300,000 units) was given intramuscularly daily for ten days Two intravenous injections of oxophenarsine hydrochloride were administered Nitrofurazone was applied to the lesions for twenty-six days None of these medications was of benefit Fractional dosage of low voltage roentgen therapy has seemed to retard further extension of the lesions but has not caused involution

DISCUSSION

DR HARRY E ALDERSON The patient stated that his trouble started in the nose His nostrils are completely occluded Unfortunately, I was not able to examine his palate My former associate, Dr Esteban Reyes, of San Salvadore, has sent me many photographs of cases of rhinoscleroma, some showing extensive vegetation on the outer part of the nose On the external part of the nose there were verrucous growths not ordinarily associated with rhinoscleroma There could

DR HOWARD FOX At first glance this swelling looked like a paraffinoma It is a lymphedema of unknown origin, and I do not believe that anything can be done for it

DR MAURICE J COSTELLO I think that this patient should be studied thoroughly A focus of infection may be found in the sinuses During the course of the examination there was a constant seropurulent discharge from the nose, and I think temporary improvement might be obtained by the administration of sulfonamides, especially sulfathiazole I suggest a trial of streptomycin

DR A BENSON CANNON The lesions in this case remind me more of granuloma inguinale than any other condition that I am acquainted with, and I should investigate the case with that diagnosis in view I should also perform a Frei test and have a hematologist study her leukocytes and, perhaps, take a bone marrow specimen

DR GEORGE C ANDREWS I suspect a diagnosis of solid edema of the face I was also thinking of leukemia because some of the infiltration suggests that diagnosis, and hypertrophic gingivitis may occur in leukemia

Tinea Capitis (Microsporum Lanosum) in Mother and Son Presented by DR ANTHONY C CIPOLLARO

Syphilis (or Tuberculosis Cutis of a Buttock?) Presented by DR GEORGE C ANDREWS

Balanitis Xerotica Obliterans Presented by DR A BENSON CANNON

N T, a man aged 37, first consulted me on June 14, 1947, complaining of phimosis and preputial fissuring, which began fourteen months previously The lesions began with small erosions or fissures on the frenulum praeputii penis which occasioned slight stinging on micturition Healing of the erosions was followed by the development of a grayish white, scarlike process which gradually increased to form a band about the prepuce Retraction of the prepuce has become increasingly difficult, and its performance causes fissures to appear

Examination shows a compact, well built man whose blood pressure is 128 systolic and 90 diastolic He has a fairly well advanced temporal thinning of the hair The prepuce is long and presents numerous superficial radial fissures There is a dense bandlike thickening about the circumference of the prepuce extending to the frenulum praeputii penis and the urinary meatus The thickened areas have a dull, gray-white appearance The urinary meatus seems narrowed Much smegma is present in the preputial sac

The basal metabolic rate was —11 2 per cent The Mazzini reaction of the blood was negative on two occasions The blood arsenic level was 0 32 mg per 10 Gm of dried blood

With the use of a simple protective paste the fissure of the prepuce healed promptly and retraction ceased to be painful though the cicatricial changes persisted In August 1947 treatment with vitamin E (eprolin–S®) was begun in doses of 5 Gm three times daily Despite this, the tightness of the prepuce increased, and by October retraction could be accomplished only with the assistance of soaping and considerable traction On October 28 treatment with tripelennamine hydrochloride (pyribenzamine hydrochloride®) was begun with 200 mg daily, increasing to 400 mg a day Use of vitamin E was also continued After three weeks on this regimen the patient felt that he had initially shown some improvement but that the process was stationary at that time

be a superimposed infection of some sort I think that it would be worth while to look for Frisch bacilli I could not find any record of such examinations having been made here The patient is apparently in good general health, despite the extensive lesions on his nose

DR PAUL FASAL This case reminds me of 2 cases of rhinosporidiosis which I have seen I would suggest the use of antimony potassium tartrate as a therapeutic experiment

DR HARRY J TEMPLETON I thought that it was a typical vegetative lesion of bromide or iodide dermatitis

DR JAMES DRAKE While in Japan, this soldier drank almost entirely from Lister bags The possibility of the unauthorized use of an iodide as a water purifier occurs to me Has the question of iodide ingestion been investigated?

DR E K STRATTON If this eruption were in the groin I would think of granuloma inguinale I have seen cases of this disease in the groin with subepidermal pustules as well as the granulomatous lesions similar to what this case presents I agree with Dr Fasal that antimony therapy should be tried

LIEUTENANT COLONEL ROBERT S HIGDON (by invitation) Rhinoscleroma was suspected, and I have tried to demonstrate the causative agent of that disease by smears, cultures and biopsy sections, but have been completely unsuccessful thus far Bromides and iodides were also considered, and the patient was given tests accordingly, but these tests have also been without positive results

Thymoma Presented by DR FRANCES A TORREY

Ervin Epstein, M D, *President*

Frances M Keddie, M D, *Secretary-Treasurer*

Nov 15, 1946

Balanitis Xerotica Obliterans Presented by DR E A LEVIN

A Case for Diagnosis (Behcet's Syndrome? Pemphigus?) Presented by DR JOHN M GRAVES

Multiple Neuromas of the Skin Presented by DR ERVIN EPSTEIN

J W, a 24 year old white man, presents a nodular eruption below the right lower lid, on the lid and on the margin The lesions consist of shiny, smooth, flesh-colored discrete and coalescing nodules They are firm Some of the older lesions show hyperkeratosis of the surface, possibly due to previous therapy

The disease started ten years ago, after an injury The patient stated that when he arrived home some "goose pimples" were present below his right eye and that these have enlarged and slowly spread during the past ten years The lesions are asymptomatic

Treatment has included "freezing," one year ago, "burning with an electric needle," one month later, and the use of "acid" by the patient on numerous occasions since This has failed to eradicate the lesions or to stop the development of new ones

DISCUSSION

DR EUGENE F TRAUB Dr Cannon gave this patient pyribenzamine,® and to the best of my knowledge it has not been used in this disease before, although patients with scleroderma show considerable benefit from its use Certainly Dr Cannon has helped this patient and that is to be remembered, as it is the first drug that has influenced this disease, as far as I know

DR HOWARD FOX I suggest circumcision and think that it would relieve the whole trouble The little band is in the foreskin

DR A BENSON CANNON I am under the impression that a number of cases have been reported in which this condition is said to have followed circumcision and that one should avoid that operation, if possible, under these conditions This patient had symptoms suggestive of endocrine disturbance, such as sweating of the palms, rapid pulse and other emotional disturbances and a basal metabolic rate of —12 per cent It was because of these symptoms that we prescribed diphenhydramine (benadryl®) He had had large doses of vitamin E uninterruptedly for four months without any change in his condition

A Case for Diagnosis (Carcinoma of the Mouth? Gumma of the Mouth?) Presented by DR ANTHONY C CIPOLLARO

A Case for Diagnosis (Sarcoid?) Presented by DR GEORGE M LEWIS

A Case for Diagnosis (Sarcoid? Syphilis) Presented by DR MAURICE J COSTELLO

Syringoma Presented by DR GEORGE M LEWIS

A biopsy section studied by Dr Gerson R Biskind revealed neuroma The sections showed a loose fibrous stroma covered on one aspect by a thin layer of skin In the stroma were several sharply demarcated bundles of cellular tissue that had a limiting membrane of fibrous tissue The cells had a slender almost wavy nucleus The stroma around the cells was pink and homogeneous but in places might be fibrillar The cells did not show distinct palisading with the formation of characteristic Verocay bodies, this process, however, was suggested in many places The over-all pattern was highly suggestive of an amputation neuroma, except that the bundles were much more cellular The site of excision should be observed for possible recurrence The present histologic structure showed no evidence of malignancy

DISCUSSION

DR HIRAM E MILLER I am not familiar with neuromas that are not painful In my patients, all of them were painful Kyrle, however (quoted in the textbook by Ormsby and Montgomery), described painless tumors in the retroauricular region in a patient who had neuromas for three years They were lentil-sized, translucent areas Histologically the lesions consisted of bundles of delicate nerve fibers He stated that pain was absent because they were "unripe" neuromas The lesions in this case may be of a similar nature

DR ERVIN EPSTEIN This disease is apparently rare It usually follows trauma The lesions seem to resemble amputation neuromas histologically They are usually painful, but some do exist for long periods before pain develops According to the literature, all become painful eventually Plastic surgery followed by skin graft would seem to be the treatment of choice in this case

At the suggestion of Dr Arthur Curtis, treatment with sodium paraaminobenzoic acid was begun March 29, tablets, 2 Gm, were taken every three hours during the waking hours The clinical improvement has been spectacular

DISCUSSION OF TWO PRECEDING CASES

Dr Hamilton Montgomery, Rochester, Minn With respect to Dr Mitchell's case, the photograph of the patient shows a definite reaction apparently to chaulmestrol which I have been using for some time in cases of mycosis fungoides but with, on the whole, indifferent results There have been 1 or 2 cases in which striking improvement occurred Dermatitis from the use of chaulmestrol is an unusual occurrence

Dr A C Curtis, Ann Arbor, Mich Two months ago, at the meeting here, Dr Mitchell asked whether I could suggest anything that might be of value in his 2 cases of mycosis fungoides In both cases the roentgen response had been exhausted I suggested that he might try para-aminobenzoic acid Dr Zarafonetis, a member of our medical department, and I have been using sodium para-aminobenzoate in the treatment of some of the lymphoblastomas Because of its relation to the local anesthetics we thought that it might have some value in certain of the lymphoblastomas Our patients received 2 Gm of the sodium salt every two hours around the clock Dr Mitchell gave 2 Gm of the acid every three hours around the clock Some of our patients had a Herxheimer reaction characterized by redness and burning of the lesions The reaction would subside, and often the lesions would disappear The first patient we treated was something like the one Dr Mitchell showed today, a woman with a psoriasiform type of mycosis fungoides The effect of roentgen rays had long been exhausted She also improved rapidly on treatment The drug is by no means innocuous It has many disadvantages when given in large doses One is that it produces glycosuria, which seems to be related to a lowering of the renal threshold because the patient often has blood sugar values that are relatively low, 40 or 50 mg per hundred cubic centimeters In 1 patient with psoriasis hypoglycemia of such severity occurred that treatment with the drug had to be stopped Some patients have nausea and some fatigue In 1 case we had to stop use of the drug because of the Herxheimer-like effect How it acts and whether its reaction will be sustained have not been determined

Dr H E Michelson, Minneapolis My co-workers and I have tried urethane in Kaposi's sarcoma with no effect We did have some effect with nitrogen mustard We also had temporary results with nitrogen mustard in mycosis fungoides

Dr Stephen Rothman It was interesting to note in this case that, while the premycotic lesions were highly pruritic, the tumors themselves do not itch In my experience this is the rule Pruritus is present as long as there is a defense reaction of the skin against the deposition of foreign cells After the infiltrating tumor has established itself and started unlimited growth, itching subsides

The experience with nitrogen mustards in Billings Hospital has been that about in 50 per cent of the cases of Hodgkin's disease the cutaneous manifestations react favorably The practical significance of this therapy is that it is effective in cases in which the beneficial effect of roentgen rays has been exhausted However, the final outcome has not been changed so far

Dr Edward A Oliver With reference to Dr Cornbleet's patient, I have watched the man for the last seven years He has been a constant attendant in our clinic at Northwestern University, and we have always presented the case as

one of psoriasis of the plaque type Itching is present, but I have seen Negroes with psoriasis who do have considerable pruritus He gets worse and gets better I examined the slides, and I do not believe that one could make a diagnosis of mycosis fungoides from them

DR ADOLPH ROSTENBERG (by invitation) What percentage of cases of parapsoriasis en plaque become cases of mycosis fungoides?

DR HAMILTON MONTGOMERY, Rochester, Minn In a fairly large series of cases that I studied with Burkhart (ARCH DERMAT & SYPH **46**.673-690, [Nov] 1942), we came to the conclusion that parapsoriasis remains as such and does not eventuate in mycosis fungoides Mycosis fungoides may start out looking like parapsoriasis and remain as such for many years, but when the cases are studied in the early parapsoriatic-like stage histologic changes of mycosis fungoides are already demonstrable, including clumping of cells, pyknosis, karyorrhexis and multiplicity of cell types in the infiltrate Dr Sweitzer and his associates have presented a case of supposed parapsoriasis many times in the course of the last fifteen years Dr Madden obtained numerous specimens of biopsy from the beginning, about fifteen in number Two thirds of these biopsy specimens revealed definite features of mycosis fungoides, and I anticipate that this patient eventually will have all the clinical features of that disorder

DR S W BECKER I distinctly remember the late Professor Bloch saying that Brocq had abandoned the term erythrodermie pityriasique en plaque disseminée He said that he no longer held to the belief that there was a type of parapsoriasis to which he gave this name

DR OTTO H FOERSTER, Milwaukee There now are perhaps about a dozen undisputed cases of parakeratosis variegata on record The disease in several of the original cases, when seen again at a later time by Unna, was found to have undergone a clinical change and was recognized by him as mycosis fungoides

DR THEODORE CORNBLEET The initial lesion that my patient showed was a well developed tumor, which classified his disease as the d'emblee variety Subsequently there was regression to the second, or infiltrative, stage with extensive lesions Thus various stages may be present simultaneously, and their mode of evolvement and progression may follow different patterns A patient at the Cook County Hospital was treated recently with the relatively new nitrogen mustard method In a disease with a course as capricious as mycosis fungoides it is difficult to be sure, but this form of therapy seemed to have hastened this particular patient's death An autopsy was made, and the heart, liver and other viscera were found to have heavy infiltrates with characteristics of granuloma fungoides Some of the newer fission products may improve the prognosis in the lymphoblastomas, though thus far they have not done what could not be achieved with the older radiation modalities

Sarcoidosis. Presented by DR S ROTHMAN and (by invitation) DR E L LADEN

M H, a Negro woman aged 31, is a seamstress whose illness began in 1942 with a nodular lesion on her left upper arm This increased in size, and new lesions appeared on her face, right arm and left leg in the intervening years

In 1943 she suffered from short-lasting attacks of pain in the left ankle and knee This disappeared spontaneously after ten months In November 1946, she noted swelling of the proximal phalanx of the third finger, right hand This has become progressively worse

The patient was seen by the Chest Department of the University of Chicago Clinics in February 1945 Results of tuberculin skin tests with dilutions of

A Case for Diagnosis (Psoriasis? Lichen Planus?) Presented by DR REES B REES

Xanthoma Diabeticorum Presented by DR PAUL FASAL

A Case for Diagnosis (Endothelial Tumor? Angioblastoma?) Presented by DR HARRY E ALDERSON and DR CHARLES ALBERT SHUMATE

C W, a white man aged 66, presents a well outlined, dark blue patch, 4 cm in diameter, superior and posterior to his left eye Surrounding this area and extending over most of the left cheek is a hard, somewhat puffy, violet discoloration (ecchymosis) The areas are painless On the anterior frontal region are two crusted keratotic lesions There is ptosis of his left lid His serologic test for syphilis gave negative reactions

A report from Dr Ream Leachman, of Vallejo, stated that Dr Medley, an oculist, examined the patient's eyes and reported that the lesions of the left lid were noninflammatory and that the ptosis was from their weight The eyeball was normal The vision, orbital contents and fundi were normal

As we believed that the disease might be the result of neurotrophic changes in the trigeminal area, for example, due to thrombosis of the posterior inferior cerebellar artery, the patient was referred to Dr Edmund Morrisey (neurosurgeon) for consultation He reported that there were no neurologic changes of significance

The histologic sections were examined by Dr Wilbert Sachs, of New York He reported that throughout the middle and upper parts of the cutis in one portion of the slide were numerous blood vessels and spaces and an intense cellular infiltration of angioblasts The surrounding tissue and overlying epidermis showed no important change The cells had large round, fairly well stained nuclei and either no cytoplasm or only a slight amount The diagnosis from microscopic study was some type of endothelial tumor, belonging to the angioblastoma group

Favorable Response of Tuberculosis Cutis (Lupus Vulgaris) to Therapy with Vitamin D Presented by DR REES B REES

A Case for Diagnosis (Multiple Areas of Superficial Atrophy of the Trunk Macular Atrophy?) Presented by DR H V ALLINGTON

Coccidioidal Granuloma on the Cheek Presented by DR OTTO E L SCHMIDT

A Case for Diagnosis (Generalized Papular and Nodular Eruption Present at Birth) Presented by DR H V ALLINGTON

C M C, a 4 month old Negro baby girl, except for her skin, was a normal full term infant weighing 5 pounds 8 ounces (2,495 Gm) She has grown and developed in an average manner She has one normal 3 year old sister There is no history of similar cutaneous trouble in her family

At birth she presented a generalized papular and nodular eruption, with lesions varying in size up to 1 5 cm in the largest diameter These were firm

given Apparently the antireticular cytotoxic serum stimulates the reticuloendothelial tissue

DR W H GOECKERMAN, Hollywood, Calif Regarding the case presented by Dr Keddie, I cannot tell you what the name of the condition is, but certainly it is not papulonecrotic tuberculid This patient has none of the characteristics of Hodgkin's disease of the skin We must allow for other possibilities In this young man the process has been present for years and years, and yet it disappears when exposed to the sun rays systematically What it is, I do not know It seems to me an interesting picture, but I am sure it is not papulonecrotic tuberculid The papulonecrotic tuberculids have a characteristic picture I have seen a great many of them

DR GRANT MORROW, San Francisco I should like to comment on the case of Dr Ingels' (multiple benign pigmented fibroma) I think it is benign melanoma We had 2 patients recently in whom lesions developed on the dorsum of the feet Both showed melanoma of benign variety

DR FRANCES A TORREY, San Francisco Concerning the case of malignant thymoma that I presented, the diagnosis was made only after examination of several biopsies I understand that thymomas are rare, and Douglas Symners (Malignant Tumors and Tumor-Like Growths, Ann Surg **95** 544, 1932) reported 25 malignant tumors or tumor-like growth of the thymic area in 17,000 autopsies (0 14 per cent) from the Pathology Laboratory of the Bellevue Hospital Hamberger (*Arch Path* **36** 37, 1943) reported that in 6,000 autopsies there were found 41 instances of tumors or enlargement of the thymus Of these only 3 were found to be malignant Under the classification of thymoma five types of malignant growths may occur (1) perithelioma from connective tissue of the walls of the blood vessels, (2) lymphosarcoma from the lymphocytic elements, (3) epithelioma from the epithelial reticulum cells, (4) spindle cell sarcoma from the connective tissue framework and (5) Hodgkin's disease from lymphocytes in the thymus Of these five, lymphosarcoma and Hodgkin's disease are the most radiosensitive This tumor was considered to be of the Hodgkin type after the first biopsy was made, and it was treated accordingly The tumor did not show any regression until after the diagnosis of epithelioma was made and the large dosage of roentgen rays was given Although the regression of the tumor has been remarkable, the prognosis, of course, is extremely poor There was a large, widely infiltrating lesion of the mediastinum that spread by direct extension to the axillas It is amazing that there has been no sign of metastasis, only the spread by direct extension

DR ARNE E INGELS, San Francisco My case was presented with the idea of clarifying the diagnosis For the pathologic diagnosis increased vascularity only does not satisfy, obviously I even thought the condition resembled pseudoxanthoma elasticum histopathologically The predominant feature was a great increase in elastic tissue, even clumping and homogenization However, clinically it did not correspond to this Otherwise, it might be a more benign xanthoma The tumor was treated with roentgen rays years ago and lost the picture of unusual singular blackish melanotic pigmentation The remaining tumor on the dorsum of the foot still retains the pigment Microscopically, it shows basal cell melanin changes within the normal So, what can it be but a benign tumor of elastic origin?

DR FRANCES M KEDDIE, San Francisco The condition of the student may not be Hodgkin's disease Clinically it does not fit with the histologic examination I had a note from Dr Hamilton Montgomery, who said it looked like malignant lymphoma The description was made by Dr Bostick, who has been interested in Hodgkin's disease for a long time I met Dr Bostick in the hall just now, and he told me he feels fairly certain it is Hodgkin's disease

The larger ones appeared to be made up of conglomerate masses of smaller ones They were, for the most part, a normal cutaneous color Some were slightly paler They seemed nontender and showed none of the signs of an inflammatory process

Since birth the lesions appear to be slowly disappearing Many of the smaller ones seem to have disappeared The largest ones are on the scalp, and several of these are a faint xanthomatous yellow, which was not so notable earlier When I last saw the baby I thought I could feel an enlarged firm nontender spleen This was not confirmed by a pediatrician who subsequently examined her

A biopsy, Aug 7, 1946, was reported by the pathologist to show stratified squamous epithelium with normal subcuticular structures In one margin of the section the subepithelial tissue was infiltrated by monocytic series cells consisting of lymphocytes and plasma cells This process extended into the deepest layers of the skin and was a diffuse rather than a dense pattern

The Kahn and Wassermann reactions were negative at birth The Kahn and Kline reactions were again negative on November 9 The cholesterol content of the blood was 150 mg per hundred cubic centimeters on November 9 The hemogram and the differential count were essentially normal

DISCUSSION

DR MERLIN T-R MAYNARD (San Jose) Is there any history of bromide ingestion in the mother?

DR H V ALLINGTON I did not question her about that

DR REES B REES I think that the occasional tremendous activity of the sebaceous glands in young children is of interest It is observed in clinics in normal babies, and babies go through that period without much difficulty

DR H V ALLINGTON I did not get the impression that the sebaceous glandular apparatus was involved I considered the possibility of its being a lymphoblastoma Also, because of the yellowish color in several of the scalp lesions at the present time, I wonder about this being another case of nevoxanthoendothelioma It is possible that if a biopsy specimen were to be taken from one of the scalp lesions at the present time, it would show a more characteristic picture

JOINT MEETING OF THE SAN FRANCISCO, LOS ANGELES AND PACIFIC NORTHWEST DERMATOLOGICAL SOCIETIES

Ervin Epstein, M D, *Presiding*

Jan 18, 1947

A Case for Diagnosis Pemphigus Vegetans? Presented by LIEUT COL ROBERT S HIGDON, Letterman General Hospital, San Francisco (by invitation)

Lupus Erythematosus or Dermatomyositis? Presented by DR EDWARD LEVIN

A Case for Diagnosis Unusual Fragility of the Skin (Related to Epidermolysis Bullosa or Ehlers-Danlos Syndrome) Presented by DR HARRY J TEMPLETON, Oakland, Calif

Epidermolysis Bullosa Presented by DR NORMAN N EPSTEIN

Sjogren's Syndrome Presented by DR H V ALLINGTON, Oakland, Calif

A G, a white woman aged 63 years, has had dryness of the mucous membranes of her mouth and eyes since 1934 This has become so severe that she has to wet her mouth with water to enable her to talk Her eyes are so dry and sticky in the morning that she has to wash them with water to get them open There are also periods when she appears to have an excess of a sticky and tenacious mucus in her mouth Her symptoms started at about the time of her menopause She has had the usual diseases and also had erysipelas and pneumonia when she was a child In 1927 she had a "nervous breakdown," which was thought to be from overwork Severe attacks of arthritis began about 1937, and she has had recurrences since then lasting from three to four days but apparently decreasing in severity as time goes on A systolic blood pressure of from 170 to 200 mm of mercury has been present for years

There are no objective changes in the mucous membranes The lacrimal glands are not palpable The salivary glands are small but palpable and are not tender

There is clubbing of the finger nails and mild hypertrophic changes in the small joints of her fingers The blood pressure was 200 systolic and 100 diastolic The reaction to the Schirmer test was 7 mm in 5 minutes (normal 21 to 25 mm) Her eyes otherwise were reported normal by Dr J R Sharpsteen, Oakland, Calif, except for a mild defect of conversion The blood count and urinalysis were essentially normal

A vitamin A concentrate of 25,000 units, given three times daily, has been of no benefit Hormones have not yet been tried

DISCUSSION

DR W H GOECKERMAN, Hollywood, Calif The last case interests me more than anything I have observed in years but not because it was called "Sjogren's syndrome," since I do not know whether that means anything If the patient came into my office and told me of the dryness of her mucous membrane, I would not know how to approach the case I went further into the history and talked at some length to the patient She told me that she does not know if she has any coldness in her fingers Her friends have told her that her hands are cold I saw that she had a peculiar sort of erythematous livid condition of her fingers There is a definite vasomotor disturbance, secondary disturbance of nutrition to the finger nails My first thought would be to give her estrogen I think it is not uncommon to see vasomotor disturbance in those along in years, even up into the seventies, as the result of endocrine imbalance I should like to suggest that a systematic effort be made to give estrogen therapy in this case under whatever name you may call it This is to me a mild disturbance which we frequently see for years following the menopause

DR SAMUEL AYRES JR, Los Angeles Perhaps there is some disturbance in the involuntary nervous system Pilocarpine, 1/20 to 1/10 grain (3 to 6 mg) three times daily, might affect the stimulation of the salivary glands and perhaps will stimulate the production of tears

A Case for Diagnosis (Behcet's Syndrome? Pemphigus?). Presented by DR JOHN M GRAVES

V H, an American woman aged 52, was presented at the meeting of the San Francisco Dermatological Society on Nov 15, 1946

Verrucous Lupus Erythematosus? Nevus Verrucosus? Presented by DR STUART C WAY and DR JAMES R DRAKE

Lupus Erythematosus, Accentuated by Solar Sensitivity. Presented by DR ARNE E INGELS

Tuberculosis Verrucosa Cutis Presented by DR STUART C WAY and DR JAMES R DRAKE

Keratoderma of Buttocks (Syphilitic or Pyogenic? Psoriatic?) Presented by DR WILLARD M MEININGER

Maduromycosis Presented by DR HIRAM E MILLER

Subcutaneous Granuloma Annulare? Presented by DR HIRAM E MILLER

S S is a 4 year old girl Her mother stated that seven months previously she noticed a small lump under the skin on the lower part of the patient's right leg and on the extensor surface of the right elbow These areas have become progressively larger in size

The physical examination reveals two rather diffuse, cherry-sized, firm, subcutaneous nodules, not freely movable and nontender, with no overlying cutaneous changes, located on the extensor area of the right elbow and on the anterior surface of the lower part of the leg

In July 1946 roentgen ray examinations showed no pathologic bony changes in the right tibia and fibula, the right elbow and forearm or the skull In September 1946 there was noted increased density in the soft tissues of the right elbow The density was sharply outlined and homogeneous and appeared to conform to the position of the supinator muscle No evidence of abnormality was seen in the bones of the forearm In the roentgenograms of the right tibia and fibula there was a localized swelling of the soft tissue situated anteriorly over the tibia, in the region of the junction of the upper and middle thirds, but the bone structures of the tibia and fibula were normal In November 1946 there was increase in the size of the mass on the anterior superior surface of the right tibia The density in the left elbow was less definite

Agglutination reactions for brucellosis were negative The tuberculin cutaneous test gave a negative reaction The sedimentation rate was 8 mm per hour The hemogram showed 4,450,000 erythrocytes and 5,100 leukocytes, with neutrophils 10 per cent, lymphocytes 86 per cent and monocytes 4 per cent

On Dec 4, 1946, a biopsy was performed on the nodule of the right leg The specimen consisted of an incised piece of yellowish gray tissue of elastic consistency with some surrounding connective tissue It measured 1 4 by 1 2 by 0 9

DR H V ALLINGTON, Oakland, Calif This is the third patient whom I have recently seen with the complaint of dryness of the mucous membranes of the eyes, nose and mouth This problem has been discussed in the American literature by ophthalmologists more than by dermatologists (MacLean, A L Sjogren Syndrome, *Bull Johns Hopkins Hosp* **76** 179-191 [May] 1945, Freedman, B, and Gerrard, H Sjogren's Syndrome Treated with Stilbestrol, *California and West Med* **64** 31 [Jan] 1946), deRoetth, A Hypofunction of the Lacrimal Gland and the Sjogren's Syndrome, *Lancet* **65** 423-425 [Dec] 1945) It has been reported as occurring in women after the menopause It has usually been associated with other diseases, especially arthritis or focal infection In some patients there has been a swelling of the salivary and lacrimal glands early in the course of the disease, with atrophy later The changes in the eyes may be marked, sometimes progressing to a severe keratitis and corneal erosions

Vitamin A deficiency has been suspected, and administration of vitamin A has been reported as helping in some cases It made no difference in this patient and in 1 other whom I have seen

Because of its association with the menopause, an endocrine background has been suspected, and the administration of stilbestrol has been reported as helping temporarily

Scleroderma Circumscriptum and Morphea Guttata Presented by DR CHARLES W MCNITT, Reno, Nev

Localized Scleroderma Presented by DR FRANCES A TORREY

Scleroderma? Diabetes Mellitus Syphilis of the Central Nervous System? Presented by DR JULIAN C LUNSFORD, Oakland, Calif

Scleroderma Presented by DR DAVID BOHR (by invitation)

Scleroderma Presented by DR DAVID BOHR (by invitation)

Poikiloscleroderma with Calcinosis Presented by DR FRANCES A TORREY

Calcinosis Cutis Presented by DR HIRAM E MILLER

DISCUSSION

DR WALTER R NICKEL, San Diego, Calif The case of a single lesion on the back (localized scleroderma, presented by Dr Torrey) I think is a case of lichen sclerosis et atrophicus There is definite plugging in the central portion of the lesion The condition of the man with stiffness of his hands and forearms I would say resembles more closely acrosclerosis There is typical sclerosis of the "V" of the neck area, along with inability to open his mouth fully or produce wrinkling of the forehead

DR D E H CLEVELAND, Vancouver, B C Are there any further suggestions as to treatment? In 1 case of acrosclerosis and scleroderma I have used 150,000 units of calciferol (vitamin D_2) daily The patient thinks he is better, but I do not think he is

DR NELSON PAUL ANDERSON, Los Angeles Etamon chloride® (tetraethyl ammonium chloride), a new drug produced by Parke, Davis and Company, is being used at the University of Michigan for peripheral vascular disorders It is

cm The sections revealed a young-appearing mesenchymal connective tissue and surrounding fat, both containing numerous endothelium-lined vessels and a mild inflammatory reaction There were several focal areas of necrotic degeneration with surrounding pseudopalisading of cells There were also bits of eosinophilic intercellular material suggesting the presence of fibrosis The diagnosis was "subcutaneous nodule consistent with rheumatic nodule or with granuloma annulare"

No treatment was given

Erythema Annulare Centrifugum Presented by DR ERVIN EPSTEIN

Sickle Cell Anemia with Ulcers on the Legs Presented by DR NORMAN N EPSTEIN

DISCUSSION

DR HIRAM E MILLER, San Francisco My case is presented as an example of subcutaneous granuloma annulare This is the second patient that we have seen with this condition in the past year The lesions in both cases were firm, subcutaneous, nontender and cherry sized and were tightly bound down to the deeper structures The focal areas of coagulation necrosis with a palisade-like arrangement of the infiltrate seem to be compatible with the diagnosis Grauer and Wile described this variant of granuloma annulare in the ARCHIVES (**30** 785, 1934)

DR ERVIN EPSTEIN, San Francisco In the patient with erythema annulare centrifugum the lesions change a great deal from week to week I have been seeing her for more than a year, so I can make this statement with certainty The condition appeared entirely different one week ago At one time it was thought that the condition might be granuloma annulare, but further observation has established the present diagnosis This histologic picture is consistent with erythema annulare centrifugum At first the possibility of a phenolphthalein eruption was also considered, but the discontinuance of the use of this drug for the past year has not resulted in a lessening of the activity of the condition The patient has had a great deal of treatment, with little benefit However, sulfadiazine by mouth has repeatedly resulted in prompt clearing of the eruption Discontinuance of administration results in just as prompt recurrences

DR NORMAN N EPSTEIN, San Francisco In our experience sickle cell anemia is rare The subject was well covered by Cummer and La Rocco in 1940 Certain interesting points relating to this condition might be mentioned The name "sicklemia" probably fits the condition much better because people with sickling of their red blood cells are not always anemic Many of them go into periods of profound anemia, and later their blood may regenerate to a normal condition The anemia may be transient in this group of patients It is a condition primarily found in Negroes but is not absolutely restricted to that race Some cases have been reported in the white race, among Sicilians and Mexicans About 8 per cent of Negroes have sickling of their blood I do not know in what percentage anemia develops The anemia found is of the hemolytic type Ulcers are one of the symptoms Other symptoms may be referable to the liver, heart, spleen and other viscera The origin of the ulcers is well understood They are peculiarly shaped It is not a specific ulceration as far as one can determine Whether it is due to the anemia is a question Certainly, in other severe anemias ulcers of the legs are not reported frequently But in 75 per cent of the patients with sickle cell anemia these ulcers do occur They are probably due to trauma plus

supplied for experimental use only At the University of Michigan they have used it in this group of peripheral vascular diseases, including Berger's disease In 1 personal case of Raynaud's syndrome with scleroderma-like changes in the skin, together with definite ulceration and impending gangrene, I felt that amputation would be required shortly The patient improved after therapy with this new drug, and the affected digits apparently have been saved Persons so treated should not drive a car for several hours as there is prompt interference with visual accommodation While I do not feel that this drug by any means solves the problem of peripheral vascular disease, yet it is to be considered for use in persons who have ulceration, impending ulceration or early gangrene of digits

DR NORMAN N EPSTEIN, San Francisco In the case of generalized scleroderma (presented by Dr Bohr) the condition was severe when the patient first came into the clinic It was so severe that he could hardly open his mouth He was given artificial fever therapy With this, he improved A second patient came in at the same time with a condition which was almost identical and was also given fever therapy This woman did not improve We have not tried fever therapy in many cases, but I think it has benefited that man Certainly, it increased the basal metabolism and increased the blood flow to the skin I think it is worth while to try the artificial fever therapy, once a week for ten weeks, in cases of this type

DR FRANKLIN I BALL, Hollywood, Calif With regard to the diagnosis of scleroderma in a patient who is diabetic (case presented by Dr Lunsford), if this is an instance of scleroderma, it is certainly not the usual picture which one expects to see I was much more impressed with the possibility that this was an instance of degeneration of the connective tissue elements of the skin, possibly amyloidosis cutis

DR W H GOECKERMAN, Hollywood, Calif I am interested in that woman whose lesions were essentially unilateral (case presented by Dr McNitt) I would suggest the diagnosis of lichen albus For years there has been discussion as to whether lichen albus belongs to the lichen planus group We got away from that conception, but where it does belong I do not know I still hold that lichen albus is a disease entity, not of the same nature as any form of scleroderma or of lichen sclerosis et atrophicus The cause is entirely obscure

DR WALTER R NICKEL, San Diego, Calif There is no evidence of lichen sclerosis et atrophicus in the girl The upper layer of the corium showed typical sclerosis, with atrophy of the appendages, without the homogenized edematous character of lichen sclerosis I think it is a pure case of unilateral scleroderma

DR REES B REES, San Francisco I agree with the last speaker

DR CHARLES W MCNITT, Reno, Nev I believe this interesting group might well form a small symposium on so-called scleroderma I should like to invite you away from the use of that term entirely There will come a time when we will all agree with the conclusions made by Goetz in the "1945 Year Book of Dermatology and Syphilology" that this type should be called multiple progressive systemic sclerosis He does not think that we should call it scleroderma Other interested workers bore out the vascular factor and called it angiitis Some day we may say that Raynaud's disease and dermatomyositis belong in the same group I am willing to admit my ignorance, but I think we should take that broad view In 1928 Allen, in the ARCHIVES, described the same morbidity, edema, cellular infiltration, fibrosis and subcutaneous atrophy in the skin in scleroderma, in dermatomyositis scleroderma and in dermatomyositis, and stated that in all there are the same prodromal symptoms, frequent history of rheumatism, rheumatic fever and other evidences of focal infection, which relates them closely

secondary infection in a patient who has a lowered resistance due to the anemia The 6 month pregnancy in this woman is an unusual finding Only 3 cases of pregnancies carried to term in this group of patients have been reported The patients in these cases had had miscarriages some years before The pregnancy in this patient has gone on in a fairly normal manner Pregnancy may be dangerous for her since severe toxemias have occurred in pregnant women with sickle cell anemia, at times leading to a fatal termination

Multiple Benign Cystic Epithelioma Presented by Dr Edward Levin

Syringocystadenoma Presented by Dr Frederick G Novy Jr

DISCUSSION

Dr Nelson Paul Anderson, Los Angeles I appreciate having observed this group of cases I should like to comment on the case presented by Dr Novy as one of syringocystadenoma I think that is undoubtedly the correct diagnosis Many different terms have been applied to this condition Syringocystadenoma, I think, is primarily a benign adenomatous condition, involving the sweat ducts and glands It is fairly common about the lower eyelids and the axillas I do not know why the term "syringoma" is sometimes used Pollitzer's translation of Darier's book has a photograph labeled syringoma, showing involvement of the lower eyelids I do not think that biopsy is ordinarily done when the condition occurs on the lower eyelids

The case presented by Dr Ervin Epstein as one of multiple cutaneous neuromas is the first case of this condition I have ever observed, and I was not able to make a clinical diagnosis I have seen 2 cases, 1 with a solitary nodule and the other with three or four discrete nodules which clinically appeared to be fibromas However, this diagnosis could not be confirmed histologically

There was a report by Wile and Montgomery several years ago of extensive involvement of one of the breasts in a woman As I recall it, pain was a marked clinical feature

Dr Werner W Duemling, San Diego The case that interested me most in this group was the rare case of cutaneous neuroma, and I should like to emphasize the word "rare" The case which Dr Anderson credited to Dr Montgomery was the case which I reported in the Archives in February 1929 The condition, as I remember, was first described by Duhring My case was the fifth reported in the literature Birchoff straightened us out on the histology of this lesion and pointed out that there are two types of cutaneous neuromas, the true and the false The true type, of course, is made up of medullated and nonmedullated bundles of nerve fibers intertwined or interlaced, much as we saw in this section In the false type the fibers arise from neurilemma In the case which I presented the lesion involved one half of the breast area and was dull brownish red in color and extremely sensitive Special stains revealed it to be a true neuroma The patients always complain of pain and hyperesthesia

Dr Hiram E Miller, San Francisco The patient with cutaneous neuroma without pain is of particular interest to me As far as I can recall, the few patients whom I have seen or have read about have had pain There is a report by Kyrle in Ormsby's textbook (1943) on a similar lesion without pain, described as "unripe" neuroma to account for the absence of pain

The types presented today run the gamut of scleroderma types, except for the "cardboard" form Scleroderma circumscriptum may be found with a widespread or general distribution and should not be classed as "localized" Also, diffuse scleroderma requires a better term than generalized scleroderma, as it is often confined to places such as the hands, forearms, feet and legs or face and neck The use of "white spot disease" has largely been given up, because it led to confusion between lichen sclerosis et atrophicus and morphea

The woman of 27 years of age (presented by Dr McNitt) in whom there was a relatively gradual onset of scleroderma is interesting because of the possibility of an etiologic endocrine factor associated with her pregnancy The condition is largely limited to one side She was found to have apical abscess of the second molar and an impacted wisdom tooth They should be cared for These patients often improve greatly after focal infection has been removed She has had no history of exposure to arsenic While the condition originally progressed steadily, with greater and greater spread of the lesions, she has improved on the following medication thyroid extract, 3 grains (0 2 Gm) daily, 150,000 units of vitamin A and a pancreatic extract in the form of padutin ®

To my mind this case is definitely one of scleroderma and morphea guttata Histologically, the atrophic epithelium and the hypertrophic collagen bundles characteristic of scleroderma are present The picture of lichen sclerosis et atrophicus is not present

DR HIRAM E MILLER, San Francisco I think it should be pointed out that in the case presented by Dr Bohr (S W) sympathectomy was done without any benefit I should like to state also that the large biopsy scar was the result of the surgical removal of a large piece of tissue for chemical studies

In the case presented by Dr Torrey as one of poikilosclerodermа with calcinosis there is no doubt about the diagnosis It was presented here at the last meeting in 1939

In my patient, unfortunately, all the lesions were excised except one on the left knee In both instances calcinosis cutis was of circumscribed variety

Ervin Epstein, M D , *President*
Frances M Keddie, M D , *Secretary-Treasurer*
March 21, 1947

Recalcitrant Pustular Acrodermatitis of the Hands Presented by DR J M READ (by invitation, for DR OTTO E L SCHMIDT)

Erythema Perstans Presented by DR HARRY J TEMPLETON

Hansen's Disease Presented by DR J M READ (by invitation, for DR OTTO E L SCHMIDT)

Basal Cell Epithelioma, Morphea-Like Sclerosing Type in the Nasolabial Fold Presented by DR FRANCES A TORREY

Lichen Sclerosus et Atrophicus of the Female Breast Presented by DR ARNE E INGELS

DR ERVIN EPSTEIN, Oakland, Calif The interesting feature in the case of multiple neuroma, of course, is the rarity of this condition In reviewing the literature, one is impressed by the repeated history of trauma preceding the lesions The patient refused to allow surgical intervention, so roentgen therapy is being attempted Despite the fact that nerve tissue is considered to be relatively insensitive to radiation, even one treatment of 200 r produced some improvement

Circumscribed Myxedema of the Legs Presented by DR STUART C WAY and DR JAMES R DRAKE

A Case for Diagnosis Nevoxanthoendothelioma? Presented by DR H V ALLINGTON (From the Berkeley Hospital Clinic, Berkeley, Calif)

The case of G M C, a 6 month old Negro baby girl, was presented on Nov 15, 1946, at the meeting of the San Francisco Dermatological Society

Nevoxanthoendothelioma Presented by DR MAX E KRAUSE

The case of G T, a white boy aged 9 months, was presented at the meeting of the San Francisco Dermatological Society on Nov 15, 1946 Thus far there have been no signs of regression of the lesions

Necrobiosis Lipoidica Diabeticorum Presented by DR FRANCES M KEDDIE

DISCUSSION

DR NELSON PAUL ANDERSON, Los Angeles Localized myxedema may come on acutely and be so inflammatory as to mislead the thyroid surgeon and the cardiologist I have seen one instance of localized myxedema in a Chinese leper who had undergone thyroidectomy In a recent article, someone writing on the subject of leprosy described lesions of this type occurring in connection with it

Necrobiosis lipoidica diabeticorum was first described as a clinical entity in the latter part of the third decade of this century I should like to call your attention to an article in the *American Journal of Medical Sciences* (Goldstein, E, and Harri, J Xanthoma Diabeticorum An Unusual Process of Evolution, *Am J M Sc* 173-195 [Feb] 1927)

DR MERLIN TREVOR-ROPER MAYNARD, San Jose, Calif For the Negro child with the diagnosis of nevoxanthoendothelioma I should like to offer the diagnosis of urticaria pigmentosum In this child wheals would definitely be produced after stroking I think that a biopsy and stains for mast cells should be made, which are characteristic of this condition

DR J WALTER WILSON, Los Angeles I too should like to follow Dr Maynard's suggestion as to the diagnosis in the case which Dr Allington presented under the title of "nevoxanthoendothelioma" I think that the correct diagnosis is urticaria pigmentosa I was interested in the conversation with the mother, who states that whenever the child is rubbed, wheals appear in "little spots" I tried to elicit the sign known as "Darier's sign," in which friction produces whealing limited to the pigmented areas I do not believe that this can be demonstrated

Pityriasis Rubra Pilaris of Nine Months' Duration in a Woman 62 Years of Age Presented by DR FRANCES M KEDDIE

Dermatomyositis Presented by DR J M READ (by invitation, for DR WILLARD M MEININGER)

O McC, a 26 year old white American housewife, has had frequent sore throats and earaches since the age of 15 years She had taken sulfonamide drugs and penicillin frequently in the past three years One and a half years ago she first noted muscle stiffness in her arms, legs and neck, which was not associated with any infection of the upper part of the respiratory tract About four months ago the stiffness became worse and gradually increased to cause almost complete invalidism Cutaneous swellings appeared, and the skin became tight and hard and sensitive to heat and to touch The facial edema and difficulty in swallowing began three weeks ago

Numerous erythematous plaques and patches are seen on her trunk and the proximal portions of her extremities A brawny induration of the muscles seems to attach them to the overlying skin

The results of a urinalysis and a hemogram were normal The result of the heterophil agglutination test was normal The serologic reaction for syphilis was negative The roentgenograms of the chest, elbows and hands revealed no abnormalities The chemical content of the blood per hundred cubic centimeters was cholesterol 250 mg, calcium 10 mg, inorganic phosphorus 4 2 mg, total proteins 6 0 mg, albumin 4 4 mg and globulin 1 6 mg The basal metabolic rate was +13 6 per cent

A section of the epidermis and a bit of adjacent muscle showed occasional small collections of lymphocytes about small arterioles, but no eosinophils and no evidence of tissue destruction or involvement of the arteriolar walls The diagnosis was focal, chronic myositis and chronic, mild dermatitis

DISCUSSION

DR FRANCES M KEDDIE I would like to suggest the diagnosis of periarteritis nodosa The patient has had episodes of diarrhea, but none of the stools was bloody These were often accompanied with fever for about four days She has been receiving sulfonamide drugs intermittently during that period There are nodules on the ulnar aspect of the right forearm which might be compatible with a diagnosis of periarteritis nodosa This seems to belong in that group of cases in which Rich and his associates were doing experimental work on rabbits Rich administered horse serum to the rabbits and also gave sulfonamide drugs and was able to produce the lesions of periarteritis nodosa A biopsy of one of these nodules on the patient's arm might confirm this diagnosis

DR HARRY E ALDERSON It would be unusual for a person with periarteritis nodosa to survive after three years

DR FRANCES M KEDDIE More cases of chronic disease are being recognized now

DR ERVIN EPSTEIN Dermatomyositis, periarteritis nodosum, scleroderma and disseminated lupus erythematosus may be classified in a single group There is considerable overlapping between these entities It is often difficult to separate these conditions clinically

DR WILLARD M MEININGER The onset and course of this condition were characteristic of dermatomyositis The patient first noticed stiffness in her legs,

Thymoma Presented by DR FRANCES A TORREY

The case of J N S, a 36 year old white woman, was previously presented before the San Francisco Dermatological Society on April 26 and Sept 13, 1946

Since the last presentation the following roentgen therapy was given From Sept 16 to Oct 3, 1946, a total dose of 3,000 r was delivered to each of two fields, the right and left axilla, with a filtration of 0 25 mm of copper and 1 mm of aluminum From Nov 19 to Nov 27, 1946, an area measuring 2 5 by 6 cm in the anterior cervical region was given 2,400 r with a filtration of 0 25 mm of copper and 1 mm of aluminum From Jan 20 to Feb 11, 1947, an area in the left cervical region measuring 7 by 7 cm received 3,000 r with a filtration of 0 25 mm of copper and 1 mm of aluminum

Thymoma in J N S

A Case for Diagnosis Multiple Benign Pigmented Fibroma Presented by DR ARNE E INGELS

D D, a white married woman aged 48, had had a lesion on her heel which started at the age of 15, a lump on the dorsum of the foot and one on the right forearm There was a gradual increase in the size of the tumor of the Achilles tendon, until it was 4 to 5 cm in diameter by June 29, 1945 The two other lesions increased slowly in size They have been brownish-blackish in appearance all the time The tumor on the dorsum of the foot was flat, blackish-brownish and approximately 1 5 cm in diameter

areas of erythema on the trunk and proximal portions of the extremities and puffiness of the face and ankles Muscle biopsy showed mild dermatitis and myositis

I want particularly to get suggestions as to treatment The patient has had reactions to drugs in the past I thought that the condition was fairly closely related to scleroderma and gave her an insulin-free pancreatic extract, but her condition is unchanged

DR ERVIN EPSTEIN In 1 case of dermatomyositis I have gone through the gamut of therapeutic possibilities I have given adrenal cortical extract, penicillin, an insulin-free pancreatic tissue extract, glycine and ephedrine Now the patient is getting fever therapy The disease does not seem to be improving

DR GEORGE V KULCHAR As I recall, particularly in 1 case, pyrotherapy was the most effective form of treatment

DR FREDERICK G NOVY JR My impression is that the cutaneous changes fit in better with the diagnosis of dermatomyositis than of periarteritis nodosa

Acne Rosacea with Ocular Involvement Presented by DR J M READ (by invitation, for DR OTTO E L SCHMIDT)

A B, a 46 year old married white American woman, was first seen on March 17, 1945, because of a rash on her face of six to eight weeks' duration which has appeared in the spring and fall for the past eight to nine years For two weeks she has noted photophobia and redness of her eyes The photophobia has appeared every year in spring and fall, at the same time as the rash on the face She gave no history of atopy

The erythematous patches and the acneform pustules are confined to the central oval of her face The keratoconjunctivitis is more pronounced in her left eye Treatment has consisted of sulfur-resorcin lotion and riboflavin, 10 mg three times daily

DISCUSSION

DR HARRY J TEMPLETON This process is rather typical of rosacea keratitis, which has been described by ophthalmologists as yielding specifically to riboflavin therapy

DR HARRY E ALDERSON Naturally one would think of the possibility of achlorhydria It is seen fairly often in rosacea with acne and in the keratitis rosacea which this patient presents

DR REES B REES The ophthalmologists think that superficial fractionated roentgen therapy is of real value in this condition Perhaps 50 r, unfiltered, once a week for several weeks, might be beneficial

DR MERLIN T-R MAYNARD (San Jose) Along the line of therapy, one seems always to have trouble in getting a response I have a patient, a boy of 14 years of age, whose mother has had severe rosacea for many years This boy had grown to be 6 feet 4 inches (193 cm) tall When I saw him he had severe rosacea with large acne pustules and keratitis such as this woman has I gave him vitamin A, 100,000 to 150,000 units, 15 mg of riboflavin by mouth daily and 5 mg of riboflavin by injection every third day Within ninety days he was free of all symptoms, including the keratitis I think that this woman should be given active therapy along these lines

On the lower portion of the Achilles tendon there is a discolored, firm, sessile lesion, 3 cm in diameter, which is grayish-brownish pink It is freely movable and has no infiltrating growth The dorsum of the right foot shows a brownish black, slightly raised lesion, 1 5 cm in diameter, which is well defined and freely movable with no inflammatory changes On the right forearm is a scar from the excision of one of the lesions There is no glandular enlargement

The physical examination shows a healthy woman with abdominal scar formations from previous operations for cystic ovaries, appendicitis and peritonitis The scalp shows four atheromas On the left side of her face is a darkly pigmented mole

The Wassermann reactions were negative on repeated examinations The blood count showed 4,100,000 red cells, 79 2 per cent hemoglobin, 6,400 leukocytes, 78 per cent polymorphonuclear neutrophils, 18 per cent lymphocytes, 1 per cent eosinophils

Hodgkin's Disease of the Skin (Generalized Erythroderma with Scattered Papules) Presented by DR FRANCES M KEDDIE

A Case for Diagnosis Hodgkin's Disease of the Skin Presented by DR FRANCES M KEDDIE

G E, a 17 year old student, has had a papular eruption since he was 7 years old This eruption has recurred each winter and has cleared up each summer after about two weeks of exposure to the sun With each recurrence there have been more lesions which have gradually become larger in size

The eruption is polymorphous There are papules and firm pustules 1 to 2 cm in diameter These are in the skin and can be freely moved over the underlying tissue They heal with slight scarring Some are excoriated, but few cause itching The lesions are distributed on the trunk and on the extremities

The physical examination showed a normal healthy boy except for the cutaneous disorder The blood count and urinalysis gave normal results

Biopsy has been twice performed, and on each examination the histopathologic process was essentially the same (One section was made at the Mayo Clinic in May 1944 and the second at the University of California in December 1946) The second section is reported on by Dr Bostick as follows "Immediately beneath the epithelium and in the subpapillary dermis there was a proliferative reaction composed of large pleomorphic cells, often in the giant form and some of them with prominent nucleoli There was a background of round cells, scattered fibroblasts, granular leukocytes and eosinophils The most proliferating and pleomorphic cells seemed to be of reticuloendothelial origin, and these extended in small groups down to the underlying dermis Careful examination with acid-fast stains, Giemsa stains and Gram stains showed no evidence of specific organisms"

A diagnosis of Habermann's disease was made in 1944, and the treatment that was given included administration of sulfonamide compounds, ultraviolet radiation and vitamins A and D in large doses None of these caused abatement of the eruption No roentgen therapy has been given

Mycosis Fungoides, Plaque Type Presented by DR FRANCES A TORREY

Mycosis Fungoides Pruritic Infiltrated Patches Presented by DR FRANCES A TORREY

I was disappointed in the results of treatment with riboflavin and vitamin A when I first used them In the absence of hydrochloric acid in the stomach, they have to be given in much heavier doses The response is always slow

DR OTTO E L SCHMIDT Riboflavin probably is specific for rosacea keratitis Patients respond to injections of riboflavin much better than to the oral administration of it

Frederick G Novy Jr, M D, *President*

Frances M Keddie, M D, *Secretary-Treasurer*

Sept 19, 1947

Recalcitrant Pustular Eruption of the Extremities Presented by DR REES B REES and DR EDWIN M HAMLIN (by invitation)

Cutaneous Hodgkin's Disease Presented by DR FRANCES M KEDDIE

O C, a white woman aged 48, was presented at the meeting of this society on Jan 18, 1947 From a biopsy of a lymph node from the left axilla the diagnosis was malignant lymphoma

A Case for Diagnosis (Psoriasis? Lymphoma?) Presented by DR FRANCES A TORREY

Lupus Erythematosus with Dissecting Pyoderma of the Scalp Presented by DR NORMAN EPSTEIN

Acrodermatitis Perstans Presented by DR ROBERT A STEWART

Vegetative Pyoderma Controlled with Streptomycin Presented by LIEUT COL ROBERT S HIGDON (by invitation)

Pemphigus Vulgaris Presented by DR REES B REES

Superficial Epitheliomatosis Presented by DR GRANT MORROW

DISCUSSION

DR H V ALLINGTON, Oakland In one case I prescribed podophyllin in isopropyl alcohol The patient was asked to use it daily if the reaction was not too severe It could not be applied every day because of irritation and soreness When the reaction became annoying, the patient would interrupt the treatment for a few days and then resume it When I last saw him the lesion had undergone involution to a great extent

Urticaria Pigmentosa in an Adult Presented by DR LEO COLUMBUS, Berkeley

Urticaria Pigmentosum Presented by DR ERVIN EPSTEIN, Oakland

Acrosclerosis Presented by DR GRANT MORROW

J M, a white man aged 42, was admitted to the Southern Pacific Hospital in August 1947 He complained of dull intermittent pain of two years' duration in

DISCUSSION

DR ERNEST K STRATTON, San Francisco, Calif Since reporting in 1942 the perimental transfer to mice from a patient with mycosis fungoides, I have made nilar transfers of tissues from 3 additional patients

The first was transferred on March 26, 1945 The case was far advanced at e time, and the patient died shortly thereafter All the animal inoculations have en negative to date The second, from 1 of the patients shown here this morning, is transferred on May 29, 1945 The specimen was placed in an icebox at 78 C for seven days It was then thawed and emulsified, and portions were jected into the brains of 6 mice and into the peritoneal cavity of another 6 One these mice (brain injected) died on June 10, 1946 (thirteen months after injec-in) Its liver was enlarged five times and its spleen enlarged twenty times icroscopic studies showed infiltrations similar to the picture of mycosis fungoides

The third transfer, from M J , was made on July 31, 1945 The tissue was st emulsified and then passed through a Seitz filter before being injected into mice intraperitoneally On May 6, 1946 (ten months after injection) 1 of the ice became ill and was killed Its spleen was ten times normal size Micro-opically it showed a mycosis fungoides type of cellular infiltration A portion this spleen was emulsified, and a second passage has been made

On July 31, 1945, when the first passage was made, whole blood from this tient was also injected intraperitoneally into 6 mice These mice were killed cently and their organs were normal The original emulsion from this patient as also inoculated onto the chorioallantoic membranes of eggs In 1 embryo mors developed on the eye and on the heart This type of reaction is being udied further

Another interesting observation in the last 2 cases was the fact that the mouse mors were produced by using a "cell-free" emulsion (in the case in which the ssue was Seitz filtered before injection) and a "dead cell" emulsion (in the case which the tissue was frozen for seven days before injection)

In view of these findings, it would seem that if there could be any correlation tween mycosis fungoides in the human being and that reaction which has been bserved in the mouse (in 3 cases out of 4), it would, I believe, favor the theory at the etiologic agent in mycosis fungoides is a toxin or a virus rather than a alignant tumor cell

DR D E H CLEVELAND, Vancouver, B C The most interesting point about ese cases of mycosis fungoides is the fact that the patients have had the disease r a length of time and yet are in excellent general health Also, only 1 of em, I believe, had had anything resembling the ulcerative lesions of mycosis ngoides, squashed-tomato-like tumors I also belong to that group who regard ycosis fungoides as a clinical and not a histopathologic diagnosis Udo Wile put in those words almost—mycosis fungoides is a clinical and not a pathologic entity eerman says that any case shown to be a manifestation of Hodgkin's or lympho-rcoma should be so named (*Am J M Sc* **211**:479, 1946) The histopathologic naracteristics are seen from time to time in other groups of lymphoblastomas ecently an autopsy on a patient whom I had had under observation with clinical ycosis fungoides for about two to three years showed the disease to be unques-onably giant follicular lymphoblastoma Antemortem biopsy of a lymph node owed the same Ulcerative lesions gradually developed

I have been studying our cases of malignant lymphoma in the Vancouver eneral Hospital for a ten year period Approximately 50 per cent of the patients ith Hodgkin's disease and 50 per cent of those with follicular lymphoma (giant llicular lymphoblastoma) had generalized erythroderma exfoliativa, in many lcerated In 1938 Dr Ormsby said, when observing 1 of these cases, "If I had

the back of his neck For two months he has had in the joints of his extremities a pain associated with coldness, weakness, swelling and hardening of the skin of his hands and feet In the past two months he has lost 20 pounds (9 Kg)

Examination shows the skin of the face, hands and feet to be hardened and edematous without pitting His hands and feet are cold, but the arterial pulses of both are good There is limitation of movement of about 20 per cent of the hands and feet

The Kahn reaction was negative The electrocardiogram showed a left axis deviation The blood cholesterol was 256 mg per hundred cubic centimeters, sugar 82 mg, urea nitrogen 8 mg, uric acid 4 mg and calcium 9 5 mg Repeated blood cell counts were within normal limits except on one occasion when the eosinophil count was 35 per cent. The roentgenograms of the chest, spine and pelvis showed no abnormalities Examination of the feces did not show blood and parasites

A stellate ganglion block was performed but effected no change Since Sept 3, 1947, seven injections of a pancreatic preparation (padutin®), each of 10 units, have made little difference

DISCUSSION

DR ARNE E INGELS The combination of padutin® with thyroid should be considered

DR EUGENE OSTWALD There is a difference between oral and muscular administration of padutin® I believe that the intramuscular administration is by far better and more effective Intramuscular injections can be given without any ill effect, and without reaction, once or twice daily for a long period of time

Papulonecrotic Tuberculid or Lupus Erythematosus? Presented by DR RICHARD O PFAFF, San Jose, Calif

Unexplained Edema of Nose Presented by DR FREDERICK G NOVY JR

Poikiloderma Vasculare Atrophicans (Jacobi) Presented by DR GRANT MORROW

R S, a white woman aged 54, born in Austria of Italian parentage, was first seen on June 9, 1947 She stated that itching of her arms and legs started six months ago and has gradually increased in severity On the skin of the arms and legs are symmetric, round, atrophic, 1 to 3 cm areas with telangiectasis The skin is dry and scaly The dermatitis simulates that of roentgen dermatitis

Physical examination showed the blood pressure to be 140 systolic and 80 diastolic There were no abnormal findings The blood cell count was within normal limits The Rumpel-Leede test showed increased capillary fragility The treatment has consisted of rutin (vitamin P), 60 mg three times a day The pruritus has greatly decreased The Rumpel-Leede reaction is now only slightly positive, and the patient feels much improved

DISCUSSION

DR EUGENE OSTWALD I would like to call this acrodermatitis chronica atrophicans, and I believe that the patient presents rather characteristic changes The skin at the elbows is bluish red, wrinkled and parchment like

not seen the slides, I would have called it mycosis fungoides" Jackson would have called it Hodgkin's granuloma Extensive cutaneous involvement does not present the picture as generally seen—great big lymph nodes in the neck The big nodes are chiefly in the axillas and groins

DR NELSON PAUL ANDERSON, Los Angeles I cannot agree with the diagnosis presented by Dr Ingels I believe that these lesions are really fibroxanthomas in which fat stains will undoubtedly show definite fat globules These give that peculiar yellowish color to the lesions, which was well shown in the one over the Achilles tendon You will not find xanthoma cells because the fibrotic tissue is predominant I do not think that they are ordinary pigmented fibromas

One patient with mycosis fungoides showed poikiloderma-like cutaneous changes on the anterior aspect of the trunk

Finally, I should like to call your attention to the more recent work dealing with mycosis fungoides and Hodgkin's disease More particularly, as dermatologists, we are interested in mycosis fungoides treated with nitrogen mustard Earl Osborne, of Buffalo, personally told of 3 cases of mycosis fungoides responding well to nitrogen mustard treatment Four cases at the Cedars of Lebanon Hospital in Los Angeles have responded with apparent involution of the tumors Two more patients are about to be treated, and 1 additional patient at the General Hospital is now being treated with nitrogen mustard Dr Ray Allington, who is acquainted with the cases at the County Hospital, might tell us of his experience with nitrogen mustard.

DR RAY ALLINGTON, Los Angeles I do not know the exact dosage recommended, but I believe it is given in small amounts in isotonic sodium chloride solution by means of intravenous drip and is given only three or four times on consecutive days to complete a single series One of the patients in our ward has had such a series of one of the nitrogen mustard preparations and has responded amazingly well Two of his lesions had been given roentgen therapy, but all were benefited by the drug We should like to see more patients so treated

DR FLETCHER HALL, Los Angeles Discussants so far have taken up all the cases in the group, except the case of Hodgkin's disease of the skin (?) presented by Dr Keddie, which I should like to introduce into the discussion I could not help but think of the diagnosis of papulonecrotic tuberculid when I first saw the patient Then, on reading in the history sheet what the Mayo Clinic said, I was thrown off the track I could not see any microscopic signs in the slide exhibited which would account for the clinical appearance of the lesions, and I wonder if it was a truly representative section of one of the lesions as presented by the patient today In view of the history and clinical findings, I should treat this patient for papulonecrotic tuberculid

DR SAMUEL AYRES JR, Los Angeles I felt the same way about this case The distribution of the lesions on the legs and arms predominates, and the eruption is worse during the cold weather It is better in the summer It strikes me that papulonecrotic tuberculid is the most probable diagnosis

In regard to the cases of mycosis fungoides I should like to say that I have been working with the A C S (antireticular cytotoxic serum) during the last year or so I have 1 patient who apparently has had a remission with the serum which was furnished by Dr Straus, of the Cedars of Lebanon Hospital The case was typical, microscopically and clinically, although not a far advanced one One case in which the serum failed was a far advanced case Another case apparently got out of control A C S serum, I think, is worthy of a trial, with little risk The results are not as dramatic as those reported with nitrogen mustard Dr Straus, pathologist at the Cedars of Lebanon Hospital, told me personally of a patient with lymphosarcoma who apparently recovered after A C S was

DR PAUL FASAL I agree with Dr Ostwald that this is a case of acrodermatitis chronica atrophicans The patient was born in Austria, a country where such cases seem to be much commoner than in this country A case of poikiloderma vasculare atrophicans of such long standing would resemble a roentgen dermatitis and not only show atrophy

A Case for Diagnosis (Periadenitis Mucosa Necrotica Recurrens?) Presented by DR ERVIN EPSTEIN, Oakland

A Case for Diagnosis (Pigmentation and Atrophy of the Face and Neck, Lupus Erythematosus?) Presented by DR H V ALLINGTON, Oakland

Localized Scleroderma Presented by DR ARNE E INGELS

A Case for Diagnosis (Angioma Serpiginosum?) Presented by DR H V ALLINGTON, Oakland

Sarcoidosis Presented by DR ERVIN EPSTEIN, Oakland

J C A, a 27 year old Negro, was first seen on Dec 16, 1946, because of an eruption on his face, neck, elbows, knees, perianal area and penis The condition started with parotitis in January 1943 This was followed by joint pains for which he was hospitalized in an Army hospital Investigation revealed roentgenologic evidence of enlargement of the mediastinal lymph nodes and parenchymal infiltration in the lungs The tuberculin reaction at this time was reported as "questionable" His electrocardiogram revealed inversion of the T wave in the first lead While he was in the hospital, generalized lymphadenopathy, cutaneous nodules and iridocyclitis developed Biopsy of a lymph node was said to have showed the histologic picture of sarcoid

When first seen, nearly four years after the first attack, he presented multiple discrete and coalescing nodules in the aforementioned locations The lesions were elevated, firm, nontender and in some instances umbilicated On the face particularly, the nodules were grouped around the eyes, nose and mouth Lesions were present on the nasal mucous membrane There was enlargement of the cervical, posterior cervical, supraclavicular, inguinal and axillary lymph nodes Corneal opacities were present

The biopsies from the skin and the lymph nodes showed epithelioid tubercles without caseation and occasional giant cells in the derma which were considered diagnostic of sarcoidosis

Numerous blood cell counts gave essentially normal findings Results of multiple urinalyses were normal Intradermal tuberculin tests elicited negative reactions to both the first and the second strengths Six Kahn tests gave positive reactions One Kolmer test gave a positive reaction, two were doubtful and one negative His wife is being treated for latent syphilis The total blood proteins were 6 9 mg per hundred cubic centimeters, the albumin being 2 72 mg and the globulin 4 18 mg Results of six blood calcium tests ranged from 12 to 14 mg per hundred cubic centimeters Nasal scrapings did not reveal acid-fast bacilli Roentgen studies revealed a few indefinite nodules in the upper lung fields and enlarged noncalcified nodes in both hili Roentgenograms of the hands, abdomen and lumbar vertebrae were normal Electrocardiograms showed diphasic and negative T waves in the four chest leads, indicating myocardial damage

1 1,000, 1 100 and 1 10 and undiluted tuberculin were all negative A roentgenogram of the chest showed moderate enlargement of the hilar lymph glands bilaterally Results of laboratory studies in 1945, including urinalysis, complete blood cell count, serologic reactions, and serum protein, were all essentially normal No skeletal lesions were found in 1945

The patient was seen in the Dermatology Clinic on May 13, 1947 Examination revealed multiple nodules and plaques on the face, extensor aspects of the arms and the left leg These lesions are firm and elastic to touch Many of the face lesions are depigmented The plaquelike lesions show a tendency toward central involution with a spreading border The lesions are dull brown to purplish Enlargement of the proximal phalanx of the third finger of the right hand was noted A roentgenogram of the hand showed widening of the base of this phalanx The medullary spaces are widened with intervening thin trabeculae The cortex is intact.

Treatment with vitamin D_2 (drisdol®), 150,000 units daily, was started on May 13, 1947 On May 16 she noted a flare-up of the cutaneous lesions with subjective throbbing sensations When seen on May 20, the flare-up had partially subsided, but some swelling was still noticeable

A biopsy specimen of a cutaneous lesion showed mild acanthosis of the epidermis The dermis contains a dense infiltrate consisting of lymphocytes, epithelioid cells and a few polymorphonuclear leukocytes In the deeper part of the corium there are well defined nests of infiltrate surrounded by connective tissue Vascular dilatation and some connective tissue degeneration are present

DISCUSSION

DR H E MICHELSON, Minneapolis I think that Negro patients having what is known as sarcoidosis should be observed in a most thorough manner to determine whether this uniform condition as seen in Negroes is the same as sarcoidosis in white persons, which might enable one to find out whether sarcoidosis is or becomes tuberculosis I have tried vitamin D_2 in 5 patients, with the dosage used in lupus vulgaris, and have seen no appreciable results

DR ARTHUR C CURTIS, Ann Arbor, Mich Although sarcoid is a clinical entity, I do not think that it is an etiologic one, unless one wishes to consider that perhaps a chemical compound is its cause This may be illustrated in the work originally done by Florence Sabin, when she began her work on fractionation of the tubercle bacilli She injected each fraction into animals, and sarcoid lesions developed in those receiving the phosphatide Further work has been done by others The late Dr Gardner, of Saranac Lake, insufflated animal lungs with silica dioxide and obtained typical sarcoid lesions Later Dr Allon in Toronto repeated Gardner's work and obtained the same results but noted considerable fat in the sections He then extracted these lungs with a solvent, removed the silica and reinjected the silica-free material into animals and again obtained sarcoid-like lesions This work indicates that silica may be an etiologic factor in sarcoid, silica produces the phosphatide which Sabin showed to be the chemical substance capable of producing sarcoid in animals

Not long ago a young man was seen with a typical sarcoid lesion of the face, proved by biopsy Dr Weller saw a few particles of silica in this lesion The next time I saw the patient I learned that two years previously he had been in an automobile accident and thrown out of his car, abrading his cheek on a gravel road I think that his sarcoid was due to silica ground into his cheek by the accident

Dr Michelson said that he has used vitamin D_2 without success That is not my experience The patients my co-workers and I have selected have had extensive

sarcoidosis, much as Dr Rothman presented today, where there was involvement of bone, lymph glands and skin We have studied the cases extensively by biopsy, chemical studies and roentgenogram In this series, to be presented before the Society of Investigative Dermatology, many showed striking improvement with vitamin D_2 and dihydrotachysterol therapy

DR STEPHEN ROTHMAN I agree with Dr Curtis that sarcoid structure has a multiple etiology, sarcoid leprosy, sarcoid syphilis and foreign-body sarcoids being important examples Still, there is a rather well defined entity of "sarcoidosis" with characteristic involvement of skin, bone, eyes and lungs, and evidence is accumulating that this disease is of tuberculous origin The "positive anergy" to tuberculin and the tuberculin-neutralizing properties of the blood serum are present in such high percentage in our material that it must be regarded as highly characteristic for this condition

DR ARTHUR C CURTIS I did not intend to leave the impression that sarcoidosis is not a clinical entity I think that it is Nor did I mean that silica or a foreign body reaction is a common cause of sarcoidosis There are some cases in which it may be the etiologic factor

Familial Keratosis Pilaris with Monilethrix-like Anomaly of the Hair in Fourth Generation, Maternal Side Presented by DR S ROTHMAN and (by invitation) DR R J STANWOOD

Dermatitis Herpetiformis Potentiated Effect of Pyribenzamine-Sulfapyridine Combination Presented by DR S ROTHMAN and (by invitation) DR J H MCCREARY

DISCUSSION

DR STEPHEN ROTHMAN In this case tripelennamine hydrochloride (pyribenzamine®) acts not because it is an antihistaminic drug, but because it contains the pyridine nucleus The therapeutic result in this case has been strikingly good

DR ZACHARY FELSHER (by invitation) There seems to be a relation, at least in some cases of dermatitis herpetiformis, between the presence of the pyridine group in the drug and its beneficial action In 2 of our cases of dermatitis herpetiformis both nicotinamide and pyridium® (phenylazo-alpha-diaminopyridine monohydrochloride) appeared beneficial Both drugs contain pyridine groups The disease in one of these cases was absolutely refractory to sulfapyridine, yet responded to nicotinamide and pyridium® In 2 other cases sulfapyridine caused complete clearing of the eruption, but nicotinamide and pyribenzamine® had no effect In a fifth case none of the pyridine-containing drugs worked at all I do not know the reasons for this discrepancy

In 1 of our cases of dermatitis herpetiformis which was completely controlled by sulfapyridine, 300 mg of paraaminobenzoic acid daily was given simultaneously to note whether this drug would interfere with the action of the sulfapyridine as it does in bacterial infections There was no interference with the beneficial action of the sulfapyridine Perhaps this points to the possibility that the action of sulfapyridine in dermatitis herpetiformis is different from its action in bacterial infections

DR ASHTON L WELSH, Cincinnati (by invitation) I did not see the patient under discussion, but I am interested in what has been said about the use of sulfapyridine in dermatitis herpetiformis In the last year my co-workers and I have treated a number of patients who had dermatitis herpetiformis with

Before examination the patient had received treatment, including roentgen and penicillin therapy According to the patient these did not improve the condition Since then he has received promin® (sodium p,-p'-diaminodiphenylsulfone-N,N' didextrose sulfonate) intravenously and locally, vitamin D by mouth, calcium by mouth and oxophenarsine hydrochloride intravenously The eruption has improved about 50 per cent in the past nine months Most of the improvement occurred while the patient was receiving intravenous injections of promin®

DISCUSSION

DR ROBERT C LOFGREN I agree with the diagnosis and might mention that at the Fort Miley Veterans Hospital I have seen 4 cases of sarcoidosis recently. One of these cases showed an unusual grouped follicular eruption Microscopic examination of one of these lesions showed the typical tuberculoid infiltration about the hair follicles and the sweat glands This type of eruption is not usually mentioned in the literature as one of the manifestations of sarcoidosis

DR ARNE E INGELS I must say that the case is extremely unusual clinically The lesions had lasted long enough to produce atrophy I have not seen destructive atrophy Second, I did not see the sections which were presented Third, I failed to see the report of roentgen examinations I think the case deserves further consideration

DR ERVIN EPSTEIN, Oakland Histologic sections were presented and represented classic examples of sarcoid in the skin and in the lymph nodes As far as the roentgen examinations are concerned, the bones and the gastrointestinal tract showed nothing unusual The patient had some enlarged mediastinal glands but no involvement of the parenchyma of the lungs He is about 50 per cent better than when first seen The patient seemed to respond better to promin® than to anything else that has been tried

Granuloma Inguinale Successfully Treated with Streptomycin Presented by DR PAUL FASAL

A Case of Osler's Disease with Hereditary Telangiectasis with Tumerous Hemangiomas Presented by DR ARNE E INGELS

Generalized Xanthomatosis Presented by DR FRANK K HAIGHT, Oakland, Calif

Multiple Idiopathic Hemorrhagic Sarcoma of Kaposi? Stasis Dermatitis? Presented by DR ROBERT C LOFGREN

Dermatomyositis Presented by DR ERVIN EPSTEIN, Oakland, Calif

lowing 'What is your skin trying to say for you?" or "What is there of your inner self which is revealing itself through your skin?" or "What is your skin expressing?" or "What do you suppose your skin is acting out?" The physician has to be very comfortable with the idea that personal feelings and experiences will use body organs for expression Only when the physician believes that such things can happen and is personally comfortable in his own thinking about these concepts, can he bring the patient to make his contribution in treatment cooperation

NEUROPHYSIOLOGIC CONNECTIONS BETWEEN EMOTION AND SKIN DISEASE

Now it is unlikely that there is any symbolic expression of ideas or attitudes anywhere in the body which does not utilize nerve pathways, vascular changes, chemical alterations and structural tissue changes as the medium for transmitting the message In some cases the psychic stimulus acts over a short period and then wanes in strength or is neutralized by a counterphenomenon, as, for instance, the homesick man or woman who is able to return home In other cases the stimulus acts continuously over a prolonged period and is neutralized with difficulty or not at all

Having enumerated the emotions and in a general way indicated their mode of action, let us turn to the emotional states in which we encounter a linking of emotions and skin problems

NEUROTIC EXCORIATIONS

As knowledge of human emotional needs and how they are met increases the line of division between what is neurotic and what is psychotic becomes less important There is a pattern of wholesome development of personality and adaptation, and if this pattern is not approximated the many devious by-paths of attempted solution are almost legion In neurotic excoriations, for instance, the patient may already be suffering from delusions of parasitosis before the behavior which produces the excoriations begins Even if delusions are not present there is a strong need to disfigure, to suffer pain, to call attention to the self, to seek attention in a perverse way because the more healthy wholesome way was never discovered and firmly established early in life The wholesome pattern of training tends toward beauty, culture and the esthetic satisfaction of others This brings rewards of ego satisfaction, but if they are unknown to the patient and if he knows and seeks pity, shocked surprise, anxious concern or even revulsion and condemnation, he nevertheless accepts this reaction in others rather than being a complete nonentity in their eyes Most people cannot stand being ignored, and self-mutilation producing an unsightly skin,

A Case for Diagnosis (Parapsoriasis? Dermatitis Medicamentosa? Vitamin A Deficiency?) Presented by DR A A SMALL for DR O E L SCHMIDT, San Mateo, Calif

A Case for Diagnosis (Lupus Erythematosus? Senear-Usher Syndrome?) Presented by DR A A SMALL for DR W M MEININGER

A Case for Diagnosis (Xanthoma Sine Diabetes? Necrobiosis Lipoidica?) Presented by DR ARNE E INGELS

Two Cases of Epithelioma Adenoides Cysticum, in Mother and Daughter Presented by DR ARNE E INGELS

N M, the mother, is 79 years old She has tumors ranging in size from 0 5 cm up to 3 cm on her chin, face and back The tumors are light pink or red, firm to touch, embedded and not painful Many of them have a semitranslucent appearance None is ulcerated There are no café au lait spots The patient gives the impression of average intelligence The tumorous masses have been developing gradually since as far back as she can remember The patient has always been in excellent health

A biopsy, performed Oct 15, 1947, showed epithelioma adenoides cysticum

A B, the daughter, who is 15 years old, shows ill defined nodules densely studded on the midline of her face, nose and forehead and on her extremities Some of the nodules have a reddish pink appearance with a capillary design The great mass of them are colorless, firm and waxy in appearance The front of the right thigh shows a partly pedunculated tumor, vivid red and sensitive, but not inflamed

She has always been healthy, and her intelligence is about average

A biopsy, performed Oct 15, 1947, showed typical epithelioma adenoides cysticum

DISCUSSION

DR H V ALLINGTON, Oakland, Calif I thought both cases very remarkable I did not realize that nodules of the size that the older woman presented occurred in this disease

DR ERVIN EPSTEIN, Oakland, Calif The lesions are similar to those seen in tuberous sclerosis and adenoma sebaceum It is often brought out in discussions that these diseases are related

DR ARNE E INGELS The lesions are not unlike those of tuberous sclerosis, without the typical sclerosis The accepted name for the cutaneous lesions is epithelioma adenoides cysticum Sections which I expected to be ready were not I have seen cases in which microscopically the nerve elements were interspersed with the usual elements and collagen The very unusual tumor formation which you see in this case I have seen many times previously

A Case for Diagnosis (Leukemid? Purpura Urticans?) Presented by DR. A A SMALL for DR O E L SCHMIDT, San Mateo, Calif

E J, a 46 year old housewife, was well until June 1947, when she began to have weakness, soreness of her mouth and some purpuric spots on her extremities

like a social act of bravado, is preferable in certain egos to the emptiness of oblivion If delusions are present as the basis of self-inflicted excoriations which follow, we should, instead of speaking of the role of emotion in skin disorders, speak of the invasion of morbid ideas when healthy emotions and ideas are absent Happy people, i e , people with a sense of well-being, tend to seek out others and join in mutually pleasurable behavior It is when this sense of well-being is absent that an individual falls back on himself, feels himself, "tunes in on himself" to use the expression of one patient and falls prey to ideas of something morbid or unhealthy in his skin or some other part of the body

DERMATITIS FACTITIA

In dermatitis factitia we see the patient secretive about his goal He wants attention, but one must be a detective and guess he wants it He even tries out one's diagnostic acumen like the children in New York who recently ran away from home and hid in a cemetery and when found by detectives said "we just wanted to see if you were any good at your business" The patient with dermatitis factitia seems to enjoy challenging the physician to make a diagnosis for the pleasure of being enigmatic (to see if the physician knows the business of understanding people) before the real question of the motive of self-mutilation ever becomes an issue

EMOTIONS AND SKIN SENSITIVITY

Eczema There is increasing evidence that maternal rejection plays a large role in psychosomatic conditions, just as in neuroses and psychoses [1] In fact, we do not mean to distinguish between these three divisions of emotional conditions too sharply, for clinically they merge as different manifestations of the same basic emotional and ideational difficulties each merely having its own pattern and intensity This maternal rejection with its absence of affection to meet the minimum needs of love seems to leave the skin organ in a state of sensitive irritability or easy vulnerability to internal emotional conflict or external pressures or deprivations, just as the same conditions disturb heart action and normal function of the gastrointestinal tract or even prevent restful sleep Without the buffering or protective effect which a restful, secure relationship with the mother produces, we have a skin which might be subject to eczema or urticarial symptoms without there being an immunologic allergy in the patient [1] Miller and Baruch make a distinction between patients in whom asthma, hay fever, eczema and urticaria may have immunologic allergy as their source and those patients in whom

1 Miller, H , and Baruch, D D Psychosomatic Studies of Children with Allergic Manifestations, Psychosom Med **10** 275, 1948

In August 1947 she had severe vaginal bleeding which required six transfusions of blood Anemia, pronounced leukocytosis and early myeloid forms were noted in the peripheral blood

On entry to the Women's Medical Ward, Stanford University Hospitals, Aug 27, 1947, she felt well, mucous membranes were clear and pale, and the skin showed isolated red papules, 5 to 6 mm in diameter, with central pustules These red papules had an indurated base and were located on the right side of her neck, under the chin, in the right axilla and on the anterior aspects of both thighs, where some evidence of old ecchymoses was visible She had palpable inguinal nodes, a 1 cm firm node in the middle of the posterior cervical chain on the left and palpable supraclavicular and axillary nodes The edge of the liver was palpable 1 fingerbreadth below the right costal margin, the spleen was not felt She had vaginal bleeding At that time the red blood cells numbered 2,900,000, hemoglobin was 48 per cent, there were 54,000 white blood cells, with 30 per cent myeloblasts and 20 per cent myelocytes, and there were 81,000 platelets A sternal puncture showed many myeloblasts and myelocytes, with a few erythroid elements

On September 4, the uterus was packed with radium (2,400 milligram hours), and the vaginal bleeding stopped

By September 10, a severe gingivitis had developed, and the patient had a daily temperature spike to 40 C (104 F) By September 15, a large, tender, purplish indurated mass, 10 cm in diameter, had developed on the right buttock, at the site of the penicillin injections, and soon similar areas developed on the left buttock and on both arms where the patient had received injections of penicillin and morphine By September 22, the indurated, well marginated swellings on the right buttock and the right arm were covered with a brownish black crust, the patient had severe gingivitis, with a number of whitish, raised, circumscribed, necrotic lesions on the oral mucous membranes, and the liver and spleen were enlarged, as were the cervical, axillary and inguinal nodes

On October 7, the red blood cells numbered 900,000, the hemoglobin was 21 per cent and the white blood cells numbered 37,200, with 38 per cent myeloblasts By this time the black crust on the right buttock had come away, leaving a brown, indurated, well epithelized plaque underneath it The purplish areas on both arms had gradually become red at the center, and the advancing margins were still indurated and elevated about 7 mm above the surrounding skin These plaques were hot and pitted on pressure A biopsy specimen was taken from this lesion on October 10, with much oozing of edema fluid and blood, which was controlled with oxycel® gauze and pressure bandages

On October 11, the blood showed a definite shift toward older forms in the myeloid series The platelet count was 72,000 On the right forearm in the region of the elbow there developed a new raised, purplish, hot area which has been gradually spreading down the forearm the past week, until it is now about 10 by 12 cm There is some scaling of the older part of the lesion, and there the purple coloring is giving way to a pinkish hue The advancing margin is a slate gray, with numerous purple petechiae The mouth has gradually cleared of lesions The lesions on the arms, while still well marginated and tense, have become brown and nontender Her temperature has come down, and the patient is brighter

On October 15, the white blood cell count was 90,000, with an increasing percentage of mature forms, the packed cell volume was 16 mm , the bleeding time was 7½ minutes, and the clotting time (capillary tube), 2¼ minutes

Treatment has included administration of pentobarbital sodium, codeine, seconal,® acetylsalicylic acid, morphine and penicillin troches; injection of penicillin in oil

the symptoms may have nothing to do with immunologic allergy They feel that psychologic elements do not produce immunologic allergy but that in many patients similar symptoms may certainly not be the result of immunologic allergy Such patients who are not allergic in the immunologic sense would, we assume, have this sensitivity of skin in the same way that some patients have a most labile heart action, others have a sensitive stomach and others are sensitive sleepers We are especially indebted to Miller and Baruch for including in their study a control group of children Further studies of this kind with controls are much needed in this field of our mutual interest This would mean that when the child or the adult was under stress or when the relationship of the child and the mother or her substitute was endangered, the skin would be vulnerable to symptomatic reactions [2] Certainly, we observe frequently enough inflammation, itching and weeping of the skin in eczema when the patient is going through some environmental stress, which places him in a position of responsibility where he feels alone and unprotected Then he has a longing expressed in the skin by itching which calls for the soothing hand (The hand which scratches is the soothing hand, temporarily at least) He cannot weep, but his skin weeps for him Eczema patients are usually depressed and long for love, but they can't use love when they get it It may even tend to aggravate them They long to scratch instead, but they are only the more aggravated by scratching After all, love has been defined as "an itch one can't scratch" So far as itching may represent a desire for love, certainly scratching is an unsuccessful attempt to obtain it

PRURITUS ANI AND VULVAE

A later period of emotional fixation would be when in the course of psychosexual development, the potential pleasure for sexual excitement and orgasm never fully reached the genital region It remained in the anal region and scratching served the role of a sexual excitement, instead of the mature genital pleasure Pruritus ani and vulvae is not always psychologic in origin, but a psychologic factor doubtless plays a contributing role in many cases That this is true does not preclude some capacity for normal sexual function in the individual with the condition The case is not, in other words, one of a normal or a perverse way of sexual gratification, but it can include a little of both, and this should be investigated as a possibility in each case of pruritus More than one patient has said such things as the following about pruritus, "It's like being excited sexually, only one is never able to achieve an orgasm It's only excitement and tension and no let down"

2 Saul, L J Relations to Mother as Seen in Cases of Allergy, Nerv Child 5·332, 1946

and wax U S P, 300,000 units daily, from August 27 to 31, and of aqueous penicillin from September 9 to 20, administration of pyridoxine, and numerous blood transfusions At present cold packs are being placed on the tender plaque on her right forearm

Examination of the sections showed large primitive cells resembling large macrophages

DISCUSSION

DR REES B REES I should suggest ecchymosis of the type often seen in leukemia, although histologically there was no definite leukemic infiltration

DR HARRY J TEMPLETON, Oakland, Calif The diagnosis, I think, is very clear There is leukemia with hemorrhage into the skin I should like to discuss this case from the standpoint of a possibly valuable new therapy, helpful to my associates and me in a single case A couple of years ago there was referred to us in Oakland a patient with chronic myelogenous leukemia, the diagnosis was proved by an internist and a hematologist Blood counts going back a number of years showed that the case was a rather typical one Generalized erythematous dermatitis, which became extremely severe, developed The patient had had about every type of orthodox therapy, without benefit I had read an abstract at about that time in which colchicine had been pointed out as having something to do with the cell mitosis It is used by planters for treatment of seeds of plants and seedlings of plants, whereupon certain changes result in the production of entirely new varieties of the plants

We gave this patient colchicine, 1/100 grain (0 5 mg) tablets, every three to four hours to the point of tolerance, that is, until the patient got nausea, abdominal cramps and diarrhea At that time the dosage was dropped to one or more tablets a day, the number depending on how well the drug was tolerated The cutaneous lesions began to improve and then disappeared after the patient had taken colchicine for two months About two weeks ago, at my request, Dr Paul Michael rechecked the blood count He stated that the man still had the hematologic picture of myelogenous leukemia, but that something had happened, there was a decided improvement in the blood picture, with less immature cells and more approach to maturity in the cells

Drs Lunsford, Allington and I have been seeking more cases of that sort Through the kindness of Dr Torrey several patients showing lesions of the lymphoblastoma group have been started on colchicine treatment at the University of California Clinic

DR FRANCES A TORREY At the present time I do not feel that my associates and I have anything definite to report We have 3 cases diagnosed as mycosis fungoides One of them we have been following for a long time Biopsy of the skin in each confirmed the diagnosis The patients in 2 cases have been able to tolerate colchicine in a dosage of 1/100 grains three times a day But so far there has been no definite improvement However, because of the characteristics of the disease, I think it is too soon to give a report

DR HARRY J TEMPLETON, Oakland, Calif At my request Dr Leslie Smith of El Paso, Texas, started treating a patient with a lymphoblastoma with colchicine This patient responded dramatically at first, and then the condition apparently flared up The dose was increased, and I am waiting to hear Dr Smith's report of the outcome

DR JAMES R DRAKE I should like to ask Dr Templeton whether he is interested in using colchicine in treatment of other diseases of the lymphoblastoma group

DR HARRY J TEMPLETON, Oakland, Calif Yes

CANCER PHOBIA AND SYPHILOPHOBIA

These conditions are not actually cutaneous conditions but psychiatric conditions and severe ones at that, but since their nature is such as to bring them to the attention of dermatologists, some discussion of them seems pertinent in a paper of this kind Just as maternal rejection may sensitize the skin to minor or major departures from peaceful and quiet functioning, so the same state of affairs prevents an emotional buffering from morbidness of mood When a person feels unloved and does not have the interest of those who have power and wish to protect with that power, ideas spring up in the mind of destructive forces invading the organism In childhood it is the bogeyman or wild animals, while in adulthood it is the undue suspicion of burglars and violence or of invasive cancer or syphilis Syphilis or cancer is merely the later life formulation of the bogeyman or the wild animals In either case, pain, destruction of tissues and eventual annihilation are felt to be the end result In phobias there is a great distrust born of real events in early life which would normally evoke distrust There are guilt and feelings of unworthiness There is great difficulty, amounting to almost complete inability in some cases, to trust and believe in the one who would help them Out of a long-carried-over feeling of guilt they think, "I should be the victim of a destructive disease I deserve no better fate Something dreadful must happen to me to even the score I am being, or I will be, punished for my wicked thoughts and acts" In therapy the task is to have the patient feel a warmth toward others and a joy in doing for others, so that he begins to reestablish a feeling of worthiness This must provide the ground work for interpretation of the symptoms No belief in a worried person is senseless Every belief has a cause in some earlier experience There is not necessarily one thought or fantasy which, if discovered, enables the whole neurosis suddenly to disappear This happens only rarely In these cases most of the results depend on slowly enriching the empty emotional life, which has left room for morbid ideas, and coming to an understanding of why a painful thought like that of having cancer or syphilis can serve any purpose It serves to atone for some childhood misdeed or "bad thought" Only when this is understood and the patient can forgive himself, can he understand how to have a life free of the burden of constant preoccupation with such distressing thoughts Some of these patients improve and get well with a few psychotherapeutic interviews—three to six in number Most of them, however, if their disease is of more than six months' duration, need longer, more intensive psychiatric treatment and should be referred to a psychiatrist for treatment if feasible These cases can be among the most difficult in the field of psychiatry

ROLE OF EMOTION IN DISORDERS OF THE SKIN

O SPURGEON ENGLISH, M D
PHILADELPHIA

WHAT emotion plays a role in disorders of the skin is a fact accepted by most, if not all, dermatologists This fact has been well elaborated in the literature, both by those specializing in the field of dermatology and those in the field of psychiatry who have joined with dermatologists in thinking through some of the complicated disease conditions within that field of endeavor

The psychosomatic approach to any disease makes a much greater demand for knowledge of causes, pathologic processes and procedures of treatment than any single newly discovered disease This is because a whole new system of dynamic forces, emanating from the mind, which act as toxic agents, must be known and understood Emotions can be helpful phenomena in the life of man, but they can also be harmful and make him sick These emotions must be understood as causes of symptoms, with some ability on the part of the physician to assess and weigh them quantitatively It must be known what kind of pathologic changes they will produce and also how therapeutic manipulation of these emotions will cause them to lose their capacity for producing end results of disease in the skin Before passing to the role of emotions generally and what they can do, let us see what the commoner emotions are which are prone to be causes The most commonly encountered emotions are the following

1 Need for love (approval, appreciation, recognition)
2 Anxiety (fear and worry)
3 Hostility (anger, hate, aggression)
4 Inferiority feelings
5 Ambivalence
6 Guilt
7 Ambition (competition)
8 Envy

NEED FOR LOVE

The need of love is one of humanity's greatest hungers, and many other emotions are dependent on it From the cradle to the grave human beings struggle under it Some of them have a great hunger for love

From the Department of Psychiatry, Temple University School of Medicine

TRICHOTILLOMANIA

Trichotillomania is likewise not really a condition of the skin but a piece of neurotic behavior What one sees in the hairy regions are the end results of a compulsion to extract the hairs forcibly with the fingers or other means This unusual behavior starts as a perverse means of gratification, of producing, in other words, pleasurable pain Those whose behavior is of this sort are in the class of those who bite and pick the nails until the nails are painful and bleeding, crack their finger joints, stimulate the gums with toothpicks or other instruments until the gums bleed or who squeeze and press comedos until they have produced macerated areas and bruises Tugging at ear lobes, biting the lips or pinching the skin are other manifestations of efforts to produce a pleasure-pain effect on the body, because more natural and wholesome ways of relieving tension either have not been permitted or have not been taught early in life They play with themselves, stimulate themselves and usually disfigure themselves, mainly because the activity gratifies This fact is hard for average people to understand, but it is no more enigmatic than the fact that people consistently eat or drink more than is good for them In either case they (1) indulge themselves in something they enjoy, (2) they relieve tension at the moment, (3) they put themselves at a disadvantage in the eyes of others through it but (4) there is an insistent urge to repeat it for the momentary pleasure it produces From this description its sexual component can be seen To cure it, the physician has (1) to help the patient to endure the tension on cessation of the habit and (2) to get the energies channeled into more wholesome and useful directions

HYPERHIDROSIS

Excessive sweating of the hands, axillas and feet is fairly common. It probably could not be settled at the present time whether there is any inherent pathologic condition of the sweating mechanism or whether this manifestation is entirely emotionally conditioned There is considerable evidence for the latter There seems every reason to believe that the sweat gland mechanism might have as wide variation in function as the glands in the mucous membrane systems of the stomach, the intestine and the respiratory and genitourinary tracts One must grant that there is wide variation in the outpouring of secretion in these areas, and the skin response could be just as labile We see analogies in sphincter control, where in states of fear people cannot "hold their water," and it drips from the hands, axillas and feet and often other parts of the body as well Whether there is any wisdom of the body in this mechanism, that is, whether there are any conditions under which

but either have no recognition of what they need or have no technics for obtaining it Lack of it brings such untoward emotions as frustration, hurt pride, envy and jealousy Others have perverted and symbolic ways of obtaining it through excessive use of alcohol, food, sex or drugs Others know they need affection, attention and rewards, and they take the conventional kind of actions and responsibilities which bring them the love they need and its derivatives of approval, appreciation and recognition Thus, to be assured of love is a most important emotional need and sufficient gratification of this need is of the greatest importance to health, both physical and mental

There has been a general reluctance to accept the proposition that love is an actual necessity for health and happiness As a health factor it has not had the same scientific standing as the chemical symbol for iron, for example, but the more one studies man and his various illnesses, the clearer it becomes that he can live neither a healthy nor a wholesome life without it

ANXIFTY

Anxiety is one of the earliest emotions aroused and one of the most basic in the whole life of man Fear is its conscious representative but the origins of anxiety itself are largely unconscious We have to use the word "fear" in order to describe the origins, since anxiety arises predominantly out of two early life situations, namely, fear of physical harm, pain or injury and fear of the loss of love When the child is threatened with the loss of his mother's protective presence, he sustains uncomfortable sensations, in both the mind and the body, and in describing his reaction to this situation we say he fears a loss of love (meaning the loss of a friendly presence) Also, as the child comes to suffer pain from falls, bumps, rejection or punishment, he dreads its repetition Its possibilities of repetition fill him with the same uncomfortable sensation, and we call this sensation anxiety Anxiety has two components one of them being psychic and distressing to the mind in a varying degree The other, the somatic component, arises from the fact that once the distress of the psyche has reached the threshold of action the emotional energy overflows by way of the autonomic nervous system to any or all parts of the body People who in the ordinary course of life suffer from too much anxiety are people who in early life lacked a consistent supply of a reassuring, friendly presence or who were subjected to too many real pain-inflicting experiences or threats of them This allows a dread or a worry pattern to construct itself, and as life becomes more complex the things which threaten deprivation of love and security or real physical distress increase in number

Not only does the emotion of anxiety impair one's ability to enjoy life, but it has more far-reaching effects If one's energy is used up in

this would be advantageous is unknown to us MacKenna[3] suggested that "a patient suffering from pompholyx may be indicating by a psychological mechanism that he cannot use his hands and feet" However, in psychiatry, when hyperhidrosis is an accidental symptom of an otherwise more inclusive neurotic pattern, we frequently find that in the course of gaining the security which cures the other symptoms, hyperhidrosis ceases In this connection, Wittkower,[4] in a study of 50 patients with pompholyx, found them to be unusually narcissistic, and four-fifths of them had shown other outstanding neurotic symptoms prior to or at the time of onset of the condition He found them vain and affected in their manners and speech They were ambitious but afraid of failure They were afraid of getting hurt physically and emotionally They were afraid of exposing their own feelings to others If severe hyperhidrosis exists alone as the main complaint and is unresponsive to local treatment, psychotherapy should surely be utilized As in blushing or more particularly the fear of blushing (erythrophobia), the patient may be reluctant to spend the time necessary to get at the emotional basis of a symptom which appears simple in nature but actually has a great deal of psychopathologic material underlying it Should the patient decide to undergo intensive psychotherapy for a symptom like pompholyx or erythrophobia, there is no question but that his personality would derive great benefit as a result of the changes he would have to make to get rid of his symptom The patients rarely realize that they need to get any help with their personality, generally feeling adequate in this area However, in making this need clear to the patient we may help him to decide that the treatment for the removal of just one symptom, which at first glance looks tedious and expensive, should be undertaken Just one such symptom may render a patient ineffectual and miserable, so the fact that the treatment offers two benefits may be the means of getting him to accept and participate in the therapeutic program

URTICARIA

Urticaria is one of the conditions of the skin for which an emotional factor has been noted and accepted for some time As yet it becomes difficult to specify the emotional trends which, among other factors, enter into this condition Stokes, Kulchar and Pillsbury[5] concluded

3 MacKenna, A M B Psychosomatic Factors in Cutaneous Disease, Lancet **2** 679, 1944

4 Wittkower, E Psychological Aspects of Skin Disease, Bull Menninger Clin **11** 148, 1947

5 Stokes, J H , Kulchar, G V , and Pillsbury, D M Effect on the Skin of Emotional and Nervous States Etiological Background of the Urticaria with Special Reference to the Psychoneurogenous Factor, Arch Dermat & Syph **31** 470 (April) 1935

concentrating on the feared thing, in the hope that by this wariness it can be averted, too little energy is left for happy living If this phenomenon goes on long enough and severely enough, the body can no longer function properly and symptoms of illness have arrived These come through the mechanism I have already described, by which emotional energy is converted into somatic disturbances through the autonomic nervous system We then have psychosomatic symptoms

HOSTILITY

Like the need of love, hostility is also ubiquitous Without spending too much time on the philosophic theories of the origin of hostility, let us say simply that when the human organism fails to find conditions which keep him in a constant state of well-being, he experiences an unpleasant emotion accompanied by ideas of retaliation and the use of force to gain his ends, even of destruction of the person or thing which makes him uncomfortable or which thwarts him This we call hostility It is impossible to conceive of any one in our society without any hostility whatever, but certainly small amounts can be present without too many untoward results This is true, especially if the modicum is properly blended with the rest of the personality to produce wit or zestful, spicy conversation or if it results in a wholesome competition "Get up and git," or "I'll show them," is an aggressive philosophy, which contributes to progress individually and generally But, unfortunately for society, a great deal of hostility does not take this form It does not even find vent in occasional outbursts of anger, righteous or otherwise It has to be held in check, because the child or the adolescent does not feel that his environment will tolerate any show of hostility He fears rejection or punishment, so his holding in results in repression a "burying alive" process of which the mind is capable The buried or repressed hostile activity builds up, and the more it builds up, the more labor another part of the mind has to exert to keep it from breaking out While this battle is going on there is much less energy available for friendly relations in other directions In fact, the person having this internal struggle becomes guilty about his state and not only feels no impulse toward loving but thinks that he does not deserve to be loved The results of this continual psychopathologic engrossment may be various things, one example being the obsessive thought that he will harm somebody However, we are more interested in where the hostile activity that builds up within expresses itself somatically We discover that it goes in several directions to produce disturbances of the upper and lower gastrointestinal tract and enuresis, headache, ticlike movement, probably epilepsy and disorders of the skin, and plays a role in vascular hypertension and other disorders Actually the effects of these

from a study of 100 cases that the patients were of the driving, high tension, competitive type, keyed to high pitch and perpetually intent on a destination to be achieved at no matter what expense Saul [6] seemed to find that longings for love frustrated through fears of sex in persons with a highly erotized skin were responsible for attacks Both observations have the common denominator of intense longings for achievement of gratification If we keep in mind that there are many hard-driving people who long for things without getting urticaria, but that it is this type of personality which furnishes the final factor that sets the symptom complex into motion, and that this factor can be treated and tension in this direction lowered, we have done the most fruitful thing possible toward relief of the symptoms

SEBORRHEIC DERMATITIS

Ingram [7] in 1939 called attention to the emotional instability of those suffering from seborrheic dermatitis by stating that it could vary from the sullen, sulky indolence of patients who present some of the heavier forms of acne to the high-strung overactivity of the patient with rosacea "States of anxiety, stress, and strain are conditions which the seborrhoeic will not readily tolerate" Ingram studied 100 seborrheic patients and found them hard to study, as they were not easy talkers and were afraid of persons in authority They were shy and solitary and had trouble in social contacts When with people they felt lost, exposed, uneasy and tongue-tied They could not stand hostility toward themselves They were compulsive workers and perfectionistic They were sensitive and felt inadequate As might be expected from such traits, they were unaggressive and overcompliant No follow-up treatment is reported, but it could be assumed that any cutaneous symptom present with such marked disturbances of personality should improve under effective therapy

The same author studied patients with psoriasis and found no specific type of personality, but concluded that the proportion who were maladjusted was far in excess of the proportion of such persons in the general population

As the role of emotions in cutaneous conditions becomes more widely accepted, we shall have more psychotherapeutic efforts and hence more reports of results of treatment This will be good for the morale of both dermatologists and patients alike As things stand, the patient still has too little faith in what can be done for his condition by a psychotherapeutic approach It is really hard for him to look at his emotions,

6 Saul, S J, and Bernstein, C The Emotional Settings of Some Attacks of Urticaria, Psychosom Med **3** 349, 1941

7 Ingram, J T The Seborrhoeic Diathesis, Brit M J **2** 5, 1939

forces of which people individually appear so unconscious have long since been noted by them in general in that they observed that situations gave them "headaches" or "made them sick," or they "itched for a fight" and "got their blood pressure up" over something frustrating Since people are not proud about being irritable, disagreeable, unpleasantly aggressive, arrogant, demanding, tyrannical or domineering, they remain remarkably unconscious of the hostile motivation But there are tremendous quantities of hostility latent in the human race, producing not only serious social problems but many individual symptoms of illness as well

INFERIORITY FEELINGS

To many it might appear that feelings of inferiority could exist as a social phenomenon but not one with any medical implications But feelings of inferiority are closely linked up with the basic emotions of love and hate Obviously, the person having feelings of inferiority has not had enough acceptance and appreciation There are few people who ever feel quite satisfied with themselves, but in some persons the feeling of worthlessness can be so deep as to destroy the capacity of the psychic apparatus for maintaining physiologic equilibrium Once a feeling of inferiority is deeply set, it is not easy to restore the self-esteem to a proper balance

AMBIVALENCE

"Ambivalence" is a term given to the condition of directing both love and hate toward a person or the world in general These impulses may be present practically continuously and show themselves rather subtly, or they may show themselves more superficially and plainly by a capricious change of mood and attitude, in which those associated with them are loved one hour or one day and hated and condemned the next We see a man, for instance, who protests how much he loves his wife but never listens to her requests, her suggestions, never tries to further her plans and never helps her in any tangible way We see a woman who protests that she loves her child but who never allows the child to do anything he enjoys and never lets him decide anything for himself This mixture of emotions which has the descriptive term of ambivalence, which portrays it as one emotion, can, like guilt, block off the benefits of straightforward, friendly, satisfying and wholesome human relations

GUILT

Guilt is an emotional distress resulting from criticisms voiced by the conscience, the conscience being a well preserved memory pattern of what the parents or substitute mentors said was right and proper The person undergoing guilt has reason to feel that he has not been or is not

since he is too busy looking at his skin and sees little reason why he should shift his attention to his emotions, which he considers as secondary to the state of his skin But as word gets around that one's disposition can be expressing itself in the skin, the physician can obtain more cooperation in the psychotherapeutic treatment

The emotional factor is a variable one, and no one is trying to assert that skin diseases are due to emotions alone But when emotion is a factor, it is one that must be dealt with, if well dealt with, it may be the factor which will give the most practical results in comfort and hence in satisfaction to both patient and physician Dermatologists and psychiatrists must stimulate and help each other to carry on more therapy of the emotional forces which are using the skin for their expression Psychotherapy is not a simple, easily mastered tool, and the patient is not always a willing subject for therapy But, if we try to ascertain what the role of emotions can be in conditions of the skin, we will cure the condition in occasional subjects, improve it in some, make it easier to live with in others and find the specialty of dermatology altogether more interesting through the pleasure which comes from taking a greater interest in human emotions in our daily work as physicians

3401 North Broad Street.

living up to expectations This emotion can kill the joy of living and may cause the patient to adopt a life of excessive self-sacrifice, which in the course of time produces physiologic disturbances As an emotion it acts to block the reception of impulses emanating from others of love and approval Starvation of the love needs can occur from guilt and the pathophysiologic results in the way described earlier

AMBITION (ENVY, COMPETITION)

The ambitious person does not necessarily have pathologic emotions, but he certainly runs the risk of being infected with envy or excessive competitiveness These emotions tend to produce tension, and the professional, financial and social success of many people has been paid for at a high price, i e., the price of tension, which is prone to express itself through the nervous system on many parts of the body The aggressive component inherent in these emotions plays a large role in such conditions as cardiovascular disease, migraine and vascular hypertension, and to some degree in many others A successful person can have achieved his goal by great ability and a friendly, easy-going manner, but he is *in the minority* Ambition with its attitude of competition, sometimes accompanied by envy, is all too often carried along as unnecessary equipment on the road to successful service

With this section I conclude these brief pictures of the more common and important emotions which are going to affect the skin, if emotion is playing any role whatever

HOW THE EMOTIONS AFFECT THE SKIN

Since emotions will find expression in any or all parts of the body, it is inevitable that so important an organ as the skin should be affected Probably the greatest number of ideas relating to man's actions and feelings are spoken of in reference to the heart The stomach and bowel run the heart a close second, but the skin will not be too far down the list When, for instance, a man does anything free of blameworthy motives, we allude to him as acting "with a whole skin" When we escape injury, we "save our skin" Cheating or taking advantage of the other fellow is to "skin" him To be oversensitive is to be "thin-skinned" and to be relatively impervious to the attitudes of others is to be "thick-skinned" The expression "you are a scab" or "you give me the itch" are well known and indicate the response of the skin to hostility "I blush for you" means "I identify myself with you and disapprove of you" Such expressions indicate that the skin is a potent carrier of emotions and attitudes Just as the stomach may act in a perverted way when the personality is unable to cope with a problem, so the skin may do the same Our first impression was that emotion was slower to appear in the skin than in the heart or the gastrointestinal tract, but

OLD DERMATOLOGIC DRUGS WHICH SHOULD BE RETAINED

MARCUS RAYNER CARO, M D.
CHICAGO

WE ARE living in the "Golden Age" of dermatologic therapy, or so it would seem During the decade since sulfanilamide was first introduced into therapy a procession of new potent drugs has been added to our weapons against disease With the sulfonamide compounds in all their many variations, with penicillin, streptomycin, tyrothricin, bacitracin, aureomycin and other antibiotics yet to be named, with the vitamins in all their fractionations, with radioactive isotopes, and with the host of antihistaminic drugs it would seem that the therapeutic progress in these few years is unmatched in any period in history Only time and the merciless inroads of experience will tell whether these contributions will live through the ages as permanent achievements, as have the artistic wonders of the "Golden Age of Pericles"

It is unfortunate that all these drugs have appeared on the scene as "wonder drugs" Such an introductory appraisal is not conducive to the competitive emergence of a drug of permanent value Each drug was wishfully accepted as a miracle and at once was utilized in every conceivable disease It was only after mishaps, complications and failures that the faith in miracles was shaken and was replaced by the cold, analytic scrutiny that should be the challenge of all new drugs. There is much evidence already on record that not all the advances made by the use of these new drugs are permanent steps forward In the problem of infectious diseases there is a continuous adaptation of the micro-organisms, which in time prevents their complete annihilation Many of these drugs produce sensitizations or other toxic reactions which make their continued use hazardous It is true that all the new drugs are being constantly developed and improved While improvement is always a sign of progress, it is nevertheless also an indication that there are deficiencies that need correction

In times like these, when to the casual observer we dermatologists seem to be moving from success to success, it is well for us to look backward, to appraise the past and to hold fast to what is good In

Read at the Seventh Annual Meeting of the American Academy of Dermatology and Syphilology, Chicago, Dec 9, 1948

in blushing and sweating we have very prompt phenomena which sometimes are distressing to a repressive patient Also, urticaria and allergic phenomena have a high incidence and can make their appearance quickly Hence, so far as these two phenomena often have a large emotional component, we cannot say that the skin differs from other organs because it does not respond promptly Dermatology and psychiatry share the phenomenon of having a few acute conditions and many which are slow to improve Now the skin undoubtedly is like other organs in that it may symbolically represent an inner attitude In other words, the skin may give one away The well known phenomenon of blushing embarrassment indicates "I believe you know what I'm thinking and I'm afraid and ashamed" The blush symbolizes inner excitement with fear of exposure being prominent, the exhibitionistic wish, however, triumphs over fear and shame, which would try to keep these emotions hidden

But the skin, in addition to "burning" with shame, may weep out of sadness So just as there may be an idea quickly speaking its message by way of the skin, so long-continued tensions make themselves known through activity of the autonomic nervous system In adolescence, for instance, there are many conflicting feelings of being good and bad, of being attractive and ugly, of being clean and dirty, of being intelligent and stupid, all at the same time The restless longing for attention makes them latently strongly exhibitionistic It is a paradox that at the time they wish to be most presentable, attractive, lovable, beautiful, they are affected with acne or some other disturbance of the skin But if we grant that emotions affect the function of the skin at all, then it becomes plausible that they must show their worst side through disease of the skin Both children and adults may expose their worst behavior in a bid for attention The skin may take over this action What we must keep trying to do if we are to be successful in understanding the language of psychosomatic disease is to remember that the skin can act a certain way or act out a problem, just as the whole person may act through voluntary muscle activity

Since most physicians pride themselves on being practical men, these ideas may sound impractical and fantastic to many However, the practice of psychosomatic medicine requires that the physician use other aspects of his education than physics and chemistry It requires that he (1) utilize what he knows or can learn from the poet, the story writer, the artist and the philosopher and (2) bring this knowledge to bear on his patient's approach to the symptoms in question This approach seems less reliable and is certainly less tangible than remedies which can be taken internally, intravenously, intradermally, intramuscularly or by unguentation It takes a great deal of understanding and self-confidence to ask the patient some such question as the fol-

former generations, when nothing was known of the causes of most diseases of the skin, an attempt was made to treat the conditions symptomatically Because of the surface location of cutaneous lesions it was possible for physicians to experiment widely with all possible local medications and, by trial and error over the years, to develop topical therapy that was effective Much of accepted dermatologic therapy is based on this tediously developed but long-established foundation

In modern times, when very little more is known about the causes of most diseases of the skin, the emphasis has been placed on etiology The goal set has been to achieve specific treatment pointed to correcting definite etiologic factors This orientation may in time result in a brilliant solution of many of the baffling dermatologic problems There is the drawback, however, that we may for too long be withholding relief of symptoms and even possible cure by so-called shotgun therapy while we spend precious time in taking careful aim with a precision rifle—a weapon that in many instances may not even be loaded

It has been my impression that with the frequent addition of well publicized new drugs to the dermatologic armamentarium, many old ones have undeservedly been pushed into the background of daily thinking Dermatologists now being trained are often unfamiliar with old drugs that still have merit, and they tend to rely more and more on therapeutic weapons that may prove to be ephemeral With the purpose of emphasizing those drugs that have proved to be effective over the years in the work of successful practitioners, I addressed a letter to two hundred dermatologists of experience, asking them to list drugs of long-established usage that they still prescribe Replies were received from nearly all Most of those questioned were generous in listing the drugs they use most often in their work One dermatologist referred me to the "Pharmacopoeia of the United States" (U S P) and the "National Formulary" (N F) for drugs that still have merit I heartily agree that one may practice in our specialty very competently while limiting himself to drugs listed in those two authoritative books It is, nevertheless, true that in our Academy there are many who do not have in their offices, available for easy reference, the latest edition of either work, nor even that excellent small book, the "Epitome of the Pharmacopoeia of the United States and the National Formulary" I am glad to pass on the suggestion, however, and to recommend the "Epitome," always in the latest edition, as a book that should be accessible on every dermatologist's desk A careful study of its contents is rewarding in calling to attention many official preparations, easily compounded and readily obtained, that are useful in the treatment of many dermatoses Most of these preparations have the added virtue of being relatively inexpensive

sulfapyridine Several interesting observations have been made Apparently large amounts of sulfapyridine are usually unnecessary to control the reaction if pyribenzamine® is given simultaneously The 4 to 7 tablets of sulfapyridine daily can often be reduced to 1 tablet a day if pyribenzamine® is given at the same time It was our experience that pyribenzamine® alone has not been very helpful It has not been helpful in preventing the outcropping of skin lesions Another group of 10 patients who had dermatitis herpetiformis were treated with sulfapyridine and paraaminobenzoic acid simultaneously They were given as much as 100 mg of paraaminobenzoic acid daily We observed in only 2 of these 10 patients some inhibition of the action of the sulfapyridine In the other 8 there was no apparent inhibition of this action It appears that in dermatitis herpetiformis sulfapyridine has some action on the causative bacteria which is different from the action usually attributed to this drug on the bacteria involved in other diseases The paraaminobenzoic acid alone may have some favorable action in dermatitis herpetiformis, but to date we have not treated patients who had dermatitis herpetiformis with this drug alone This should and will be done to control the study already mentioned Suggesting some unusual action of the sulfapyridine on the bacteria in dermatitis herpetiformis is the fact that in many instances only 1 tablet daily, or 1 every other day, was necessary to control this problem This has not been an observation with this drug in other diseases

DR. ADOLPH ROSTENBERG JR (by invitation) I could not make a diagnosis of dermatitis herpetiformis In order to evaluate the therapeutic result one should be sure of the diagnosis I do not know that it was a papular eczema It started eight years ago

DR STEPHEN ROTHMAN Many of the outstanding New York dermatologists who saw this patient did not diagnose dermatitis herpetiformis because the patient displayed no vesicles However, after we had done a patch test with potassium iodide, the patient had a rather characteristic vesicular eruption Dr O'Leary saw the patient at that time and agreed with the diagnosis of dermatitis herpetiformis A few characteristic grouped vesicular lesions are still present

Kaposi's Sarcoma in a 50 Year Old White Man with Tumors on the Toes Presented by DR EDWARD A OLIVER and Dermatology Staff

A Case for Diagnosis (Exfoliative Dermatitis or Pityriasis Rubra Pilaris?) Presented by DR JULIUS E GINSBURG and (by invitation) DR I EIRINBERG

A Case for Diagnosis (Glossy Skin? Morvan's Disease? Possible Radio Dermatitis?) Presented by DR JAMES HERBERT MITCHELL and (by invitation) DR ROBERT H HARRIS

Generalized Mycosis Fungoides of Six Years' Duration Presented by DR EDWARD A OLIVER and Dermatology Staff

Acrodermatitis Chronica Atrophicans Presented by DR I M FELSHER and DR A SLEPYAN and (by invitation) DR I EIRINBERG

Alopecia Areata Totalis Associated with Hypothyroidism, Regrowth of Hairs Presented by DR S ROTHMAN and (by invitation) DR Z FELSHER and DR L RUBIN

Acrodermatitis Chronicus Atrophicans Presented by DR JAMES HERBERT MITCHELL and (by invitation) DR ROBERT H HARRIS

A Case for Diagnosis (Sarcoid? Syphilis?) Presented by DR EDWIN M SMITH JR

Supernumerary Breasts in Axillas (with a Nipple [?] on One Only) Presented by DR I M FELSHER and DR A SLEPYAN and (by invitation) DR I EIRINBERG

Von Recklinghausen's Disease (Neurofibromatosis) Presented by DR FRANCIS E SENEAR and Staff

Prurigo Nodularis Presented (by invitation) by DR ROBERT C RANQUIST

Erythema Induratum and Papulonecrotic Tuberculid Presented by DR MICHAEL H EBERT and (by invitation) DR ALLEN S PEARL JR

A Case for Diagnosis (Leprosy?) Presented by DR EDWARD A OLIVER and DR SAMUEL M BLUEFARB

Lichen Planus with Atypical Microscopic Picture? Lichenoid Toxic Eruption Presented by DR STEPHEN ROTHMAN and (by invitation) DR R H SNAPP

Erythema Figurata Perstans or Tinea Superficialis Squamosa Presented (by invitation) by DR MAURICE OPPENHEIM and DR WILLIAM A YACULLO

Parapsoriasis en Plaques Limited to Flexural Areas Presented by DR EDWARD A OLIVER and Dermatology Staff

A Case for Diagnosis (Glossitis Rhombica Mediana of the Brocq-Pautrier Type?) Presented by DR JAMES R WEBSTER

A Case for Diagnosis (Parapsoriasis en Plaques? Premycotic Mycosis Fungoides?) Presented by DR RALPH H SCULL

A Case for Diagnosis (Pemphigus?) Presented by DR D V OMENS and (by invitation) DR HAROLD D OMENS and DR J GRAFFIN

Chronic Discoid Lupus Erythematosus—Persistent Despite Treatment for Thirty-Four Years Presented by DR JAMES R WEBSTER, DR SAMUEL BLUEFARB and (by invitation) DR J GRAFFIN

Scleroderma Presented by DR DAVID V OMENS and (by invitation) DR B YAFFE and DR HAROLD D OMENS

A Case for Diagnosis (Granuloma Telangiectaticum?) Presented by DR THEODORE CORNBLEET and (by invitation) DR H SCHORR and DR B YAFFE

Nearly every dermatologist of experience has his pet remedy for each dermatosis, a drug tested by time and countless usages and at times inherited from his preceptor While the use of some of these remedies may represent wishful thinking and unwarranted enthusiasm, often it represents the product of careful observation of cause and effect by good clinical observers, whose experience should not be lightly brushed aside In the practical management of a dermatologic patient it is helpful for us to keep all these remedies in mind Far too often we dermatologists exhaust all methods of treatment which are indicated on rational grounds and in the end come up against the stark fact that our patient has not been helped at all It is helpful at such a time to be reminded of drugs that empirically and often without logical justification may succeed in giving the patient at least symptomatic relief

DRUGS FOR INTERNAL USE

Of the drugs used internally arsenic compounds probably have the oldest history and the most varied career from generation to generation Centuries ago they were used as a remedy for asthma For many years they fell into disuse medically because of frequent employment as a poison In the seventeenth and eighteenth centuries they were used medicinally only by quacks for treating fever and ague One of these quack preparations was so successful that a Dr Fowler had it analyzed and published the prescription in London in 1786 The use of Fowler's solution (potassium arsenite solution U S P), as it has since been known, helped to raise arsenic compounds again to a status of medicinal respectability One need not discuss at length the importance attained by arsenic compounds with the introduction of arsphenamine ("salvarsan") by Ehrlich for the treatment of syphilis This importance was enhanced by the later development of neoarsphenamine (neosalvarsan®) and the more recent oxophenarsine hydrochloride (mapharsen®) At one time or another arsenic compounds were employed in the treatment of nearly all dermatoses They undoubtedly have some beneficial effect in many diseases Their general use was soon limited, however, by the recognition of their occasional harmful effects, such as keratoses, epitheliomas, arsenical dermatitis and visceral complications In the treatment of syphilis, however, arsenic compounds long remained unchallenged With the advent of penicillin, it seems at present as if arsenical drugs will be replaced completely even in the treatment of that disease Only time will tell whether treatment with penicillin, effective as it is in quickly rendering a syphilitic patient noninfective, will need to be followed by chemotherapy in order for one to obtain the highest possible percentage of long range cures or remissions

Arsenic compounds are still being used frequently in diseases other than syphilis Neoarsphenamine and oxophenarsine hydrochloride are

group of patients to investigate fully the effects of a drug, with the controls essential to an accurate appraisal Many clinical investigators as yet lack the mature judgment needed to temper their enthusiasms and to keep them from being carried away by clinical impressions that may not be lasting In dermatologic therapy too many are attempting to run who have not yet fully mastered the art of walking It may seem antiquated to use old drugs and old fashioned to treat patients with the simple purpose of getting them well as quickly as possible Certainly there is more glamour in being up to the minute with the use of the newest drugs and even ahead of the times in the investigation of drugs for which no specific use has yet been found Most of us dermatologists, in my opinion, are most useful, however, when we devote ourselves wholeheartedly to the career of being healers of the sick It is an old-fashioned role, devoted largely to treating diseases that are not new and most often calling for the employment of drugs that have been tested in the crucible of time It is an honorable career and a satisfying one, a career to which, in our highly scientific age, we particularly need converts.

25 East Washington Street

used in the treatment of sarcoid, tuberculosis indurativa, papulonecrotic tuberculid and lupus erythematosus, often producing considerable improvement Injections of solutions of ferric cacodylate or sodium arsenate have been employed in the treatment of pemphigus Acetarsone tablets taken by mouth have at times been effective in the treatment of pemphigus and lichen planus Asiatic pills (composed of arsenic trioxide and black pepper) and potassium arsenite solution, however, have been the most popular forms of administering arsenic by mouth, and they have been used especially in the treatment of lichen planus, dermatitis herpetiformis, neurodermatitis, urticaria papulosa, pompholyx, parapsoriasis and vitiligo In the treatment of psoriasis the use of arsenical drugs should be discouraged, for they need to be administered for too long a time to be devoid of danger It must be remembered, however, that in some persons the use of arsenic compounds for even a short period may be followed by serious sequelae

Iodine in the form of a solution of potassium iodide given by mouth is still an important adjuvant treatment of late syphilis It has also been recommended as an adjuvant to streptomycin in the treatment of tuberculosis It is an excellent remedy in cases of blastomycosis, sporotrichosis, actinomycosis, kerion celsi and other deep fungous infections At times it is effective in the treatment of arthropathic psoriasis or resistant psoriasis, a use which is seldom remembered at present In the form of strong iodine solution U S P or iodoform pills it is helpful at times in treatment of cases of lupus erythematosus Intravenous injections of a solution of sodium iodide often relieve the pain of herpes zoster

Mercurial preparations are seldom used at present in the treatment of syphilis As a therapeutic test in late syphilis, however, the oral administration of mercury and chalk tablets is very useful The oral administration of mercury with chalk or yellow mercurous iodide is often effective in the treatment of juvenile warts and lichen planus, while mild mercurous chloride is an excellent cathartic in the treatment of urticaria and toxic erythema

Bismuth compounds given by intramuscular injection have long been used in the treatment of syphilis While at present displaced by penicillin, they are still being employed in the supplementary chemotherapy of that disease In lupus erythematosus and lichen planus they are often effective, either alone or combined with arsenic as in bismuth arsphenamine sulfonate (bismarsen®)

Gold, in the form of intravenous injections of gold and sodium thiosulfate or other gold compounds, is still probably the most effective drug in the treatment of chronic discoid lupus erythematosus, although the percentage of failures with its use is increasing as the years go by

SPECIFIC SENSITIVITY TO FOODS AS A FACTOR IN VARIOUS TYPES OF ECZEMATOUS DERMATITIS

CLARENCE S LIVINGOOD, M D
GALVESTON, TEXAS
AND
DONALD M PILLSBURY, M D
PHILADELPHIA

MANY observers[1] have reported cases of chronic, recurrent, vesicular eruptions of the hands due to various food allergens Other authors,[2] who have written on the problem of eczematous dermatitis of the hands, designated by various terms such as "chronic eczematoid dermatitis of the hands" and "recurrent vesicular eruptions of the hands," have listed food allergy as one of the infrequent and relatively unimportant etiologic factors Stokes,[3] in particular, emphasized the concept that such eruptions of the hands, as well as chronic eczematous dermatitis at other sites, are often due to multiple etiologic factors He stressed the importance of a "factorial analysis" in the study of such patients and included food allergy among the various etiologic considerations

Read at the Sixty-Eighth Annual Meeting of the American Dermatological Association, Inc, San Diego, Calif, April 27, 1948

From the Department of Dermatology and Syphilology, Graduate School of Medicine, University of Pennsylvania, Dr Donald M Pillsbury, Director

For many of these patients, scratch, intradermal and patch tests were done by Dr Norman R Ingraham Jr Our associate, Dr Malcolm C Spencer, assisted in the management of some of the patients included in this series

1 Buckley, L D Diet and Hygiene in Diseases of the Skin, J A M A **59** 535 (Aug 17) 1912 Wise, F, and Wolf, J Dermatophytosis and Dermatophytids, with Particular Reference to Differential Diagnosis of Dyshidrosiform Eruptions of Hands and Feet, Arch Dermat & Syph **34** 1 (July) 1936 Wise, F, in discussion on Lehmann, C F Acute Vesicular Eruptions of the Hands and Feet, ibid **21** 499 (March) 1930 Engman, M F, Jr, in discussion on Andrews, G C, Berkman, F W, and Kelly, R J Recalcitrant Pustular Eruptions of Palms and Soles, ibid **29** 548 (April) 1934

3 Stokes, J L, Lee, W E, and Johnson, H M Contact, Contact-Infective and Infective Allergic Dermatitis of the Hands, with Especial Reference to Rubber Glove Dermatitis, J A M A **123** 195 (Sept 25) 1943

Antimony, as antimony potassium tartrate or stibophen (fuadin®), seems to be outdated in the treatment of granuloma inguinale as a result of the introduction of streptomycin Antimony potassium tartrate is still being used, however, in treatment of cases of mycosis fungoides and pemphigus foliaceus

Intravenous injections of a 10 per cent solution of sodium thiosulfate are sometimes of benefit in the treatment of disseminated neurodermatitis In the treatment of arsenical exfoliative dermatitis, however, that drug has largely been displaced by BAL (2,3-dimercaptopropanol)

Sodium salicylate given by mouth is often effective in treatment of cases of erythema multiforme and erythema nodosum, while phenyl salicylate is more often recommended for urticaria, and salicin for psoriasis Acetylsalicylic acid, alone or in combination with codeine, forms one of the most effective drugs for the relief of pain in herpes zoster

In the treatment of urticaria and other allergic dermatoses the antihistaminic drugs seem to have successfully eliminated all drugs used formerly In the urticaria that results from penicillin, however, epinephrine is often necessary for quick relief and at times ephedrine is also helpful In individual cases benefit may also be obtained after the employment of bile extracts, belladonna tincture, cascara sagrada, magnesia magma, mild mercurous chloride, phenobarbital or calcium gluconate injection

Quinine has been used in the treatment of severe acne vulgaris and resistant cases of lupus erythematosus

Foreign protein therapy, in the form of administration of bactalbumin (aolan®), a solution of peptones and proteoses derived from milk (proteolac®), milk, intravenous injections of typhoid vaccine or autohemotherapy, is often of great value for severe acne vulgaris, neurodermatitis, dermatitis venenata, psoriasis and dermatitis herpetiformis, although for the last-mentioned disorder sulfapyridine has proved to be the most effective drug in cases in which it can be employed

Of the sedatives, phenobarbital is probably the most widely prescribed drug, but at times bromides, chloral hydrate or paraldehyde are more effective when prolonged sedation is desired

Sodium chloride is indicated in the treatment of bromoderma and bromine acne It is effective in the enteric-coated tablets, and it seldom needs to be given intravenously

Vaccine therapy still has its supporters in treatment of recurrent furunculosis and pyodermas, and its employment is not completely outdated by the introduction of penicillin and the sulfonamide compounds Smallpox vaccine is often beneficial in cases of recurrent herpes zoster

In 1946, Rowe [4] reported a series of 80 patients (42 per cent of 182 patients with eruptions of the hands) with "atopic dermatitis of the hands" due to food allergy, and concluded from his observations that "dermatitis of the hands in the average population may result more frequently from atopic allergy to food than from any other cause"

At about the same time, Flood and Perry [5] reported two series of patients, 30 patients with "recurrent, vesicular eruptions of the hands" being discussed in one paper,[5a] and 13 patients with "eczematoid dermatitis" in the other,[5b] with food sensitivity comprising the primary etiologic factor Flood and Perry did not attempt to estimate the exact incidence of food allergy as the predominant factor in such eruptions, nor did they compare its importance with other factors, but they implied that specific sensitivity to foods is at least as important as any other etiologic factor

Our experience in the study and treatment of eczematous dermatitis of the hands, feet and other sites is recorded in this paper with an attempt at a critical evaluation of the relative importance of specific food sensitivity as a primary or contributory etiologic factor in such eruptions One of us (C S L) had an opportunity to accumulate considerable experience in this therapeutic approach during World War II, but none of the patients encountered at that time is included in this report because adequate follow-up was not possible All the patients in this series were seen and followed in our joint private practice We have included only those patients with an adequate period of follow-up observation and in whom a predominant role of food allergy in the eruption seemed inescapable Furthermore, we have not included patients from whom complete cooperation was not obtained This fact has limited the number of patients in our series, but it is believed that the experience with this group is representative and the major aspects of this subject are illustrated in the case material It is believed that one reason for some difference of opinion in regard to the importance of the food allergy factor in eczematous dermatitis is the failure to realize that food sensitivity is only one of the etiologic agents in many of these cases and that the complete cure and, indeed, recognition of a contributory food allergy factor depend on the identification and adequate management of all the factors concerned in the individual case This principle is well illustrated in many of our cases

It is essential to attempt to clarify the descriptive terms applied to this group of eczematous eruptions because nomenclature is cumbersome

4 Rowe, A H Atopic Dermatitis of the Hands Due to Food Allergy, Arch Dermat & Syph **54** 683 (Dec) 1946

5 (*a*) Flood, J M , and Perry, D J Recurrent Vesicular Eruptions of the Hands Due to Food Allergy, J Invest Dermat **7**·309, 1946, (*b*) The Role of Food Allergy in Eczematoid Dermatitis, Arch Dermat & Syph **55**.493 (April) 1947

Of the endocrine substances thyroid is probably used most often It is especially indicated in the treatment of myxedema and hypothyroid loss of hair, but it is also prescribed for scleroderma, onychodystrophy and, at times, for acne Posterior pituitary injection (pituitrin®), 0 25 cc (obstetric dose) given subcutaneously daily, often relieves the pain in herpes zoster and hastens the involution of the disease

Dilute hydrochloric acid is prescribed in cases of rosacea accompanied with achlorhydria

Iron compounds given by mouth, hematinic tablets and injections of crude liver are often valuable in the treatment of severe acne vulgaris, lupus erythematosus and pemphigus, but in the last-mentioned disease a blood transfusion is probably the most rapid procedure for improving the hematologic status of the patient

Preparations of the vitamin B complex, dried yeast and extract of rice polishings are used in the treatment of glossitis, perlèche, pellagra and rosacea, while vitamin A preparations are often beneficial in treatment of cases of keratosis follicularis, keratosis pilaris, ichthyosis and pityriasis rubra pilaris

DRUGS FOR TOPICAL USE

It is in topical therapy that we dermatologists have our greatest heritage It is in this field also that great skill in therapy can be acquired most rapidly by the intelligent interpretation of experience The surface location of cutaneous lesions, the ease of applying many forms of medication and the ready observation of the effects of local applications make the skin an ideal experimental organ A novice who studies minutely the clinical features of all cutaneous lesions and remembers well how they react to different drugs in various concentrations and in diverse vehicles soon has acquired the therapeutic wisdom of a veteran The careful selection of a few effective drugs and their adaptation to the treatment of various diseases in all stages of activity is much more educational than an aimless but wishful flitting from one proprietary mixture to a later one

In cases of generalized pruritus baths may be used to make a patient more comfortable. Cool colloid baths, prepared with starch, bran or oatmeal, are soothing to an inflamed skin Tar baths are antipruritic and at times are also helpful in treatment of extensive psoriasis Baths containing potassium permanganate are useful in the therapy of widespread pyodermas and of pemphigus

Cold wet dressings are often the most soothing form of treatment in acute inflammations of the skin Skim milk containing boric acid is nearly always well tolerated A saturated aqueous solution of boric acid is effective and inexpensive, while aluminum acetate solution

and confusing, especially for the physician who is not a dermatologist The same type of disease process has been referred to by various authors as eczema (with numerous qualifying terms such as vesicular and nummular), eczematoid dermatitis of the hands and feet, chronic, vesicular eruptions of the hands, "atopic dermatitis of the hands" and "eczematous contact-type allergic dermatitis," among other terms It would be desirable to use terms based entirely on etiology, but this is not possible because the cause in many cases is unknown, in other instances the etiologic agents are multiple, and they may vary from time to time in the same patient Therefore, any classification must be partly etiologic and partly morphologic There is general agreement in the use of the following terms (or various synonyms), either because the dermatitis is due to a single etiologic factor or because of the characteristic type, distribution and course of the cutaneous eruption (1) contact dermatitis, (2) dermatitis medicamentosa (eruptions due to drugs), (3) atopic dermatitis, (4) infantile eczema of atopic type, (5) seborrheic dermatitis and (6) lichen simplex chronicus

We use the term eczematous dermatitis as a morphologic diagnostic term for all other types of chronic and recurrent dermatitis due to a wide variety of external and internal causes or of unknown etiology It is the group of cases in this category which has been responsible for most of the confusing synonyms The individual entities within the syndrome are often not sharply defined, and transitional types are encountered For example, it may be difficult to determine whether the patient has a contact dermatitis with secondary bacterial infection, or a pyoderma with secondary eczematous changes due to sensitization to bacteria, or reactions to local treatment

The cataloging of the individual patient into a distinct diagnostic category depends on qualification of the term by adding the site or sites of involvement and the etiologic factors, if they are determined and proved (so far as doing so is possible) The following etiologic factors are variously recognizable in (chronic) eczematous dermatitis

1 Allergic contactant
2 Primary irritant
} (Dermatitis in which these factors are the only factors is classified under the heading of contact dermatitis)

3 Food allergy

4 Secondary bacterial invasion and sensitization (Impetigo and other primary uncomplicated pyogenic infections of the skin are not included)

5 Drug allergy (If this is the only factor the condition should be included under the heading of dermatitis medicamentosa)

6 Pollen and inhalant allergy

7 Mycotic infection and mycotic sensitization (Uncomplicated primary fungous infection and dermatophytids are classified as such)

8 Psychosomatic, traumatic, thermal, endocrine, peripheral, vascular and dyshydrotic factors and foci of infection

9 Undetermined etiologic factors

(in a dilution of 1 to 16) and a combination of the two are extremely popular In treatment of dermatitis due to plants, solutions of lead acetate (1 teaspoon to 1 quart), potassium permanganate (1 to 5,000) or strong tea generally bring relief In treatment of pyoderma or acute tineal infection of the feet alibour water (water containing zinc and copper sulfate, 1 to 20) or potassium permanganate (1 to 5,000) are of great value Solutions of silver nitrate (1 to 500 or 1 to 1,000) are efficacious in the therapy of acute oozing dermatitis and the weeping streptococcic dermatitis seen on the legs or behind the ears

Of the drying lotions, calamine lotion and starch lotion, with or without the addition of phenol and menthol, are the most widely used When the skin is to be kept from becoming too dry, calamine liniment or lime liniment may be used

Most powders contain starch, boric acid and talc, at times with the addition of other medicaments for specific purposes, such as salicylic acid and thymol in treatment of tineal infections

Soothing ointments include petrolatum, rose water ointment, hydrous wool fat, theobroma oil, lead oleate ointment, zinc oxide ointment and zinc oxide paste

Effective antiperspirants are a 25 per cent solution of aluminum chloride, a 1 per cent solution of formaldehyde and, for the feet, a 1 4,000 solution of potassium permanganate

Mercury is still one of the most efficacious drugs for topical use on the skin Except for the few persons who are sensitive to the drug, ammoniated mercury in the form of a 3 per cent to 10 per cent ointment is probably the most suitable medication for impetigo, ecthyma and other pustular infections of the skin Five per cent ammoniated mercury ointment is often rapidly effective in treatment of infected eczema of the auditory canal, and it is also well tolerated in treatment of impetiginized atopic dermatitis Its use is often beneficial in cases of psoriasis and seborrheic dermatitis One per cent ointment of yellow mercuric oxide is useful in treatment of seborrheic dermatitis of the eyelids, and in therapy of pediculosis of the eyelids it is unexcelled A 1 to 5,000 aqueous solution of mercuric oxycyanide is also an effective and clean treatment for seborrheic dermatitis of the eyelids A 1 to 1,000 solution of mercury bichloride has much support for its use in the treatment of folliculitis and also as an ingredient of scalp lotions

In the treatment of sycosis vulgaris an occasionally more effective antiseptic is quinolor® (chlorohydroxyquinoline) At times, however, its employment is followed by a dermatitis Drugs that are also excellent in the treatment of folliculitis, impetigo, ecthyma and other pyodermas are 1 per cent to 3 per cent ointment of iodochlorohydroxyquinoline (vioform®) and 3 per cent to 10 per cent ointment of bismuth tribromo-

It is realized that there are other possible contributory factors, such as physical allergies, diseases of the gastrointestinal tract, liver or kidney, intercurrent infections of various types and metabolic disturbances

METHOD OF STUDY

It is our practice to consider specific food sensitivity as a possible primary or contributory factor in all cases of eczematous dermatitis, regardless of the site of involvement, unless it is obvious on initial examination or a brief subsequent period of observation that other causes are responsible

The methods of study in regard to a possible food allergy factor which we have used include one or more of the following regimens

(1) A strict trial diet (as outlined by Flood and Perry,[5]) which is feasible only for hospitalized patients

(2) A so-called basic "nonallergenic diet," consisting of beef, lamb, chicken, canned pears, canned apricots, prunes, baked or boiled potatoes, lettuce, celery, string beans, red beets, lima beans, weak tea, sugar, salt, white vinegar, ry-krisp® or pure rye bread, peach preserves and apple jelly, followed by addition of foods one at a time at five-day intervals after a base line of improvement has been established

(Recently, following the suggestions of Winston and Sutton,[6] we have added only one food at each meal [For example, on the first day of the diet, the menu is as follows Breakfast canned pears, luncheon—canned pears and tea with sugar, and dinner canned pears, tea with sugar and lamb On subsequent days other foods of the basic diet are added in a similar manner] If pruritus and/or new lesions of any type are noted after the addition of a new food, all new foods which have been added in the previous twelve-hour period are eliminated from the diet)

(3) A minimal elimination diet ("spot" elimination diet), interdicting sea foods, chocolate, nuts, citrus fruits, tomatoes, pork, cheese and coffee

(4) A diet diary

It must be realized that considerable individualization is necessary, inasmuch as there are practical limitations in the study and treatment of patients from the standpoint of food allergy A high percentage of patients do not like strict diets, hospitalization is not available or feasible for everyone, and, on an outpatient basis, business and social responsibilities make it difficult for persons to follow even simple elimination diets There are very few patients who find it possible to eat all their meals at home, and, if they do, the necessity of special cooking for one member of the family is a complicating factor Furthermore, the vast majority of patients are not easily convinced that food allergy may constitute a factor in their particular case Only a small number of our patients will follow diets as limited as the Rowe elimination diet[6] or the so-called "basic nonallergenic" diet for more than two

6 Winston, B H, and Sutton, R L, Jr Dermatitis of the Hands Due to Ingested Allergens, Arch Dermat & Syph **58** 335 (Sept) 1948

phenate (xeroform®) Dermatitis from the latter two is uncommon, and their employment generally brings gratifying results With rare exceptions it should not be necessary for one to use preparations of the sulfonamide drugs or penicillin topically in the treatment of cutaneous infections These preparations are seldom as effective topically as the drugs previously mentioned, and their use in this form is hazardous

Sulfur has an old and honored place in dermatologic therapy For seborrheic dermatitis it still is the most effective medication, either alone in a 3 per cent to 5 per cent ointment or with the addition of 1 per cent to 3 per cent salicylic acid In various sulfur lotions, such as white lotion, sulfurated lime solution or Kummerfeld lotion (a compound containing camphor spirit, alcohol, tragacanth, precipitated sulfur and distilled water), it has retained its popularity in the treatment of acne Scabies may still be cured by the application of sulfur in a 3 to 10 per cent ointment A 15 per cent solution of sodium thiosulfate will cure tinea versicolor without any messing The pruritus of dermatitis herpetiformis is often relieved by application of a 2 per cent sulfur ointment In the form of a 30 or 40 per cent sulfur paste, sulfur is frequently beneficial in the therapy of seborrheic dermatitis, dermatitis herpetiformis, chronic eczema and other chronic dermatoses

Tar is a remedy of great value for many dermatoses In nummular eczema and infantile eczema coal tar ointment generally produces rapid improvement, and in eczema of the nipple the response is excellent Tar ointments are beneficial in treatment of tineal infection of the hands and feet and at times also in that of psoriasis and recalcitrant eruption Solutions of crude coal tar in acetone, chloroform or collodion are much cleaner to apply but are not as effective as the ointment form The various distilled or decolorized tars are also much less effective than crude coal tar, but distarol® and zetar® are comparatively good clean substitutes The wood tars (pine tar, juniper tar and rectified oil of birch tar) should be used only in chronic dermatoses, for their employment in more acute stages generally increases the inflammation "Oil of cadeberry"[1] has all the benefits of juniper tar, but it has a much more pleasant odor In treatment of resistant patches of psoriasis or lichen chronicus simplex, tar-containing ointments, such as compound ointment of sulfur or Dreuw's ointment (a preparation containing salicylic acid, chrysarobin, rectified oil of birch tar, medicinal soft soap and petrolatum) may be used Tar should never be used in any form in the presence of furuncles or other pustular infections, for fear of the production of lymphangitis Folliculitis from the use of tar can generally be prevented by removal with a bland oil of all the old residue on the skin before a new application is made

1 A product of Muth Bros & Co, Baltimore, containing barbados tar and oil of juniper berry

weeks, and, if there is no significant improvement at the end of that time, there is difficulty in persuading the patient to continue any type of dietary restriction

The evaluation of the course of the eruption is complicated by the fact that the interval between the ingestion of food and the beginning of the exacerbation varies in different patients Furthermore, there is an important quantitative factor, and, in addition, the presence of concomitant pyogenic and pyogenic sensitization, allergic contactant or other factors interferes with the interpretation of results

It was shown by many investigators [7] that limitation of the diet on the basis of scratch tests to food is rarely helpful, and our experience is in agreement with this conclusion However, many patients who do not like dietary restrictions in principle will cheerfully adhere to a restricted diet based on the results of scratch tests, often for years

Because of all these limitations, we have been obliged to use various methods of approach, including the strict trial diet as outlined by Flood and Perry, a basic nonallergenic diet which follows the general principles of the Rowe elimination diets and a "spot" elimination diet from which foods with a high allergenic index are eliminated All the patients who were studied by means of the strict trial diet were hospitalized After hospitalization, during which pronounced improvement or complete cure was affected in all patients in whom food allergy was an important etiologic factor, new foods were added at five day intervals Diet diaries were used in all cases because, for one thing, they assist patients in learning to recognize their exacerbations and to correlate them with the addition of possible causative foods

PRESENTATION OF CASES

We have been able to demonstrate either a primary etiologic or an important contributory etiologic food factor in a total of 26 patients who have had adequate follow-up observation For an additional 41 patients, specific sensitivity to food was an apparent important component of the dermatitis, but we were not able to establish unequivocal proof of this fact, or the observation period was not sufficient at the time of writing, and, therefore, their cases are not included in the series which constitutes the basis for our discussion

Lack of space makes it impossible for us to include the individual case histories of all these 26 patients Therefore, only 3 representative cases are presented in detail, pertinent data on all the 26 patients are summarized in the accompanying table

7 (*a*) Winston and Sutton [6] (*b*) Rowe, A H Elimination Diet and the Patient's Allergies A Handbook of Allergy, ed 2, Philadelphia, Lea & Febiger, 1944

Naphthalan and ichthammol (ichthyol®) in 5 to 10 per cent ointments are often helpful in the treatment of many chronic dermatoses

Chrysarobin in a 2 to 10 per cent ointment is useful in the treating of chronic patches of psoriasis and lichen chronicus simplex, while a 4 per cent suspension in chloroform works well in the treatment of chronic paronychia and tineal infections between the toes The drug is sometimes extremely irritating, and it is generally being replaced by anthralin ointment (1/10 to 1 per cent) Other drugs with similar action are pyrogallol, acetpyrogall (triacetyl pyrogallol, lenigallol®), anthrarobin and cignolin

Resorcinol is widely used in combination with sulfur lotions in treatment of acne and also in treatment of seborrheic dermatitis For use on the scalp it is available as resorcinol monoacetate (euresol®)

Salicylic acid is added to many ointments for its keratolytic effect It is an active fungicide, and in benzoic and salicylic acid ointment it probably is still the most effective medication for ringworm infections Thymol may be added (0 25 per cent) to increase the fungicidal activity Fifty per cent salicylic acid in petrolatum has been recommended in the treatment of kerion, but in my experience milder ointments have been as effective Forty per cent salicylic acid plaster is effective in the removal of calluses and corns

Silver compounds are drugs that deserve wider use than they enjoy at present Wet dressings of silver nitrate solution (in a dilution of 1 to 1,000 or 1 to 500) often produce a spectacular drying of acute, weeping streptococcic infections on the legs and behind the ears Ten to 20 per cent solutions are useful for cauterizing fissures, and I have found daily applications of 10 per cent silver nitrate solution extremely helpful in treating ingrown toe nails The granulation tissue is destroyed in these cases and is replaced by a tough crust that resists the pressure of the toe nail In treatment of seborrheic dermatitis of the eyelids a 5 per cent solution of argyrol® (a combination of silver with a protein produced by the electrolysis of serum albumin) dropped into the eye is often helpful Chronic ulcers are effectively treated by the Mikulicz ointment, which contains 1 per cent silver nitrate and 10 per cent Peruvian balsam in petrolatum

Iodine in the form of a 10 per cent ointment in lard in my experience is more efficacious in treatment of ringworm of the scalp than are the newer fatty acids Another old remedy for this disease is a 3 per cent solution of salicylic acid in tincture of iodine In alopecia areata 3 per cent iodine in petroleum benzine has the advantage of staining the skin less than does tincture of iodine or Cutler's fluid (equal parts of liquified phenol tincture of iodine and chloral hydrate) In this disease local applications of phenol, soon removed with alcohol, also act as an adequate irritant

REPORT OF CASES

CASE 1.—M. C., a housewife aged 32, was seen because of a patchy, eczematous dermatitis of twenty years' duration, involving the hands and the left lower eyelid, the eyelid having become involved only within the past four months. The eruption was characterized by erythematous, scaling, oozing, rather well demarcated, vesicular plaques on the right palm and on all surfaces of the right third finger, as well as on the sides and dorsal surface of the second and fifth fingers of the left hand. The patient had severe pruritus, which had interfered with sleep and other activities. Several weeks after she came under our observation, she also had a brief episode of an oozing, pruritic, intertriginous dermatitis of the axilla and groins. At various times vesicopustules and residual pyogenic crusts were noted as a part of the process. This patient had not been completely free of lesions since the onset, although there had been many exacerbations and partial remissions. The longest and most significant partial remission had occurred approximately two years before her first visit, during the time that she was on a reducing diet consisting of grapefruit juice, eggs, toast, cheese, tea, lettuce and tomatoes. On several occasions during the past three years, she had had attacks of intertriginous dermatitis in the axilla and groins persisting for two to three weeks, followed by a complete remission.

The patient had been treated by at least twelve different physicians, including five dermatologists, who had given her a total of approximately twenty-five roentgen ray treatments, and she had been informed by one of her physicians that he had given her as much roentgen therapy as her hands would tolerate. The use of numerous ointments and other types of local treatment, as well as the employment of a soap substitute and strict avoidance of soap and water and all household contactants, had had no apparent effect on the course of her lesions.

There was a history of infantile eczema in early infancy and of relatively transient attacks of acute urticaria in childhood. The familial allergic history was noncontributory except that the patient's sister had had apparent hydrorrhea due to vasomotor neurosis (vasomotor rhinitis) and urticaria.

The management and course of this patient's eczematous dermatitis during the eighteen months of observation were as follows:

1. Patch tests with numerous household contactants, cosmetics and routine test materials had negative results except for 1 plus reactions to dilutions of 1: 1,000 of bichloride of mercury, prell® shampoo, lustre creme® shampoo, rinso® and resorcin, although all these reactions were minimal.

2. Initially, on an outpatient basis, the patient was placed on a diet of baked potato, beef, lamb, string beans, carrots, tea, sugar, grapefruit juice, boiled eggs, canned pears, prunes, canned apricots, lettuce and tomatoes. In addition, she was asked to avoid prell® shampoo, lustre creme® shampoo, and rinso®. Local treatment consisted of potassium permanganate soaks and 3 per cent ichthammol (ichthyol®) in zinc oxide ointment. Housework of all types was reduced to a minimum by the patient's employing a full time maid and enlisting the cooperation of her husband for dishwashing when the maid was not available. She did not have significant, sustained improvement on this regimen of treatment.

3. Therefore, she was hospitalized for a period of two weeks. She was placed on a strict trial diet (Flood and Perry), with sugar water during the first twenty-four hours, baked potato during the next twenty-four hours and lamb during the next twenty-four hours, during this time there was pronounced continued improvement, with almost complete disappearance of pruritus after the first forty-eight hours. Tea was added on the fourth day, and eight hours after the first cup of tea,

Copper in the form of a 10 per cent ointment of copper oleate is therapeutically active in ringworm of the scalp, and alibour water (1 to 20) is an excellent wet dressing for Bockhardt's impetigo and other infected lesions

It is possible that hexachlorocyclohexane in a vanishing cream base (kwell® ointment) will replace all other antiparasitic drugs Until its place has been firmly established and its possible dangers are fully understood, it is well to remember that other good remedies for scabies include sulfur, Peruvian balsam and its derivative, benzyl benzoate, betanaphthol, and storax

Benzoin tincture is often applied to fissures A 50 per cent ointment of benzoin tincture is an excellent remedy for chronic ulcers, as is the application of Aloe vera leaf or ointment Urea solution is useful in removing necrotic tissue from ulcers Cod liver oil ointments are efficacious in the treatment of chronic ulcers and of burns, and for burns trinitrophenol solution is rapidly effective in treatment of patients who can tolerate it

Of the various dyes used for topical application, Castellani's paint (a preparation containing basic fuchsin, phenol, boric acid, acetone and resorcinol) is by far the most valuable in the treatment of tineal infections on moist areas It is best to begin by using a 25 per cent strength paint and then to strengthen it gradually A 1 per cent solution of methylrosaniline chloride is excellent in treatment of yeast infections, especially those on the webs of the fingers and in the folds of the skin and paronychia A 5 per cent solution of methylrosaniline chloride in 20 per cent alcohol is effective in the prevention of infection at the site of removal of warts or moles Five per cent scarlet red ointment is an old and effective remedy for chronic ulcers

For screening agents in lupus erythematosus and sensitivity to light, preparations of phenyl salicylate, quinine or tannic acid are satisfactory and are less likely to produce dermatitis than sodium para-aminobenzoate (Paba®) cream

The application of 10 per cent bergamot oil in alcohol followed by exposure to the ultraviolet rays at times hastens the return of pigment in patches of vitiligo

Five per cent ethyl aminobenzoate (benzocaine®) in flexible collodion applied to insect bites relieves the pruritus in many cases

Condyloma acuminatum is best treated by the application of 25 per cent podophyllum resin in alcohol One must exercise great care not to treat too large an area at one time, for fear of producing severe inflammation

Verrucae under the nails or about the nails may be treated by applying 4 per cent formaldehyde solution, sulfurated lime solution or mono-

Data Concerning Twenty-Six Patients with Eczematous Dermatitis

Case No	Age	Sex	Occupation	Duration	Period of Observation	Sites of Involvement	Methods of Study	Factors	Foods Which Caused Exacerbation	Comment
1	32	F	Housewife	20 yr	18 mo	Hands, left lower eyelid, axillas, groins	Hospitalization, strict trial diet, diet diary	1 Food allergy 2 Pyogenic infection and pyogenic sensitization	Tea, apricots, broccoli, cauliflower, cabbage, peaches	Pyogenic factor treated with penicillin administered parenterally
2	29	F	Nurse and housewife	1 yr	6 mo	Hands, left lower eyelid	Basic "nonallergenic" diet, diet diary	1 Food allergy 2 Contactant	Eggs, milk	Onset as contact dermatitis
3	30	F	Secretary	15 mo	1 yr	Feet, hands	Basic "nonallergenic" diet, diet diary	1 Food allergy	Wheat, chocolate, coffee, shrimp, crab, lobster	Scratch test-negative diet partially successful
4	28	M	Mail carrier	4½ yr	9 mo	Hands	Hospitalization, strict trial diet, diet diary	1 Food allergy 2 Pyogenic infection and pyogenic sensitization	Milk, chocolate, pork, tomatoes	Pyogenic factor treated with parenterally administered penicillin combined with fever therapy
5	44	M	School teacher	1 yr	3 mo	Perianal region, scrotum, hands	Spot elimination diet, diet diary	1 Food allergy	Chocolate, shad, shrimp	No resemblance of scrotal dermatitis to lichen simplex chronicus
6	30	F	Secretary and housewife	6 mo	4 mo	Hands	Basic "nonallergenic" diet, diet diary	1 Food allergy	Cinnamon, onions, eggs, smoked ham	
7	55	F	Housewife	6 mo	2 yr	Hands	Spot elimination diet, diet diary	1 Food allergy 2 Contactant	Nuts, grapefruit, oranges	Prominent psychogenic factor
8	27	M	Medical student	2 mo	16 mo	Hands	Hospitalization, strict trial diet, diet diary	1 Food allergy 2 Contactant 3 Drug	Wheat, milk, pork(?), chicken(?), carrots(?)	Exacerbations with use of naphazoline ("privine") nose drops, patient not cured until smoking was discontinued, positive reaction to patch test with tobacco
9	67	M	Civil engineer	1 yr	17 mo	Legs, ankles, thighs, hands, left upper and lower eyelids	Basic "nonallergenic" diet, diet diary	1 Food allergy	Wheat, veal, rye	No improvement until responsible foods were discontinued for several weeks—which observation is unusual
10	37	F	Housewife	6 yr	20 mo	Hands	Hospitalization, strict trial diet, diet diary	1 Food allergy 2 Pyogenic infection and pyogenic sensitization 3 Drug	Broccoli, string beans, lima beans, vanilla, peas, sweet corn	Exacerbation on ingestion of sulfadiazine and pentobarbital sodium, acetylsalicylic acid, pyogenic factor treated with penicillin given parenterally
11	31	F	Housewife	4 mo	9 mo	Hands, legs	Basic "nonallergenic" diet, diet diary	1 Food allergy	Wheat, chocolate peaches(?), pork(?)	Unusually severe, extensive involvement, with rapid improvement on management on an outpatient basis
12	30	F	Secretary	5 mo	18 mo	Hands	Spot elimination diet, diet diary	1 Food allergy	Grapefruit, peanuts, oranges	Prominent psychogenic factor
13	4	M	Preschool child	1 yr	6 mo	Buttocks, legs	Basic "nonallergenic" diet, diet diary	1 Food allergy	Eggs, chocolate, pork	Exacerbations on numerous attempts to add causative foods to diet
14	50	M	Executive	1 yr	1 yr	Hands, legs	Hospitalization, strict trial diet, diet diary	1 Food allergy	Almonds, tomatoes, pork, Scotch whisky, oranges(?)	Patient completely incapacitated by his dermatitis

chloroacetic acid Applications of trichloroacetic acid remove patches of xanthelasma Monochloroacetic acid may be used in destroying seborrheic verrucae After the Sherwell removal of an epithelioma solution of mercuric nitrate or ferric subsulfate solution may be applied

For Vincent's infection of the mouth the administration of penicillin troches is no doubt the most effective local treatment It is a mistake, nevertheless, for one to form the habit of using penicillin routinely in all oral conditions In most of them nothing is accomplished by penicillin that cannot be performed as well and more safely by mild mouth washes, such as sodium bicarbonate, magnesia magma or the N F antiseptic solution As a local astringent a mixture of kino tincture and myrrh tincture has a well founded reputation

Finally, for the treatment of itchy legs nothing brings relief as rapidly as the application of Unna's paste boot

Many additional drugs have been recommended for the treatment of various dermatoses I have excluded them from this listing either because I did not have personal experience with their use or because they duplicated without advantage other drugs that are more readily available in the average pharmacy

COMMENT

I feel certain that the medications listed have found great success in the work of some dermatologists and have been complete failures with others The fault is not entirely with the drug, for each drug is but an inanimate servant, capable only of performing the limited tasks within its scope The selection of the particular drug and the determination of the proper concentration, the ideal vehicle and the best method of application are often the factors that decide the therapeutic results In addition, the unmeasured ingredient of every medication is the attitude of the physician who prescribes it Some dermatologists have the power to inspire confidence and to obtain from the patient full cooperation in the carrying out of carefully outlined instructions For one to tell a patient merely to put on cold wet dressings, for example, is to assume that the descriptive command means to him the same as it does to the physician A patient is more likely to perform his duties correctly if he is permitted to explain to the physician just how he plans to carry out the orders and is then corrected Only by making certain that the patient is going to use the medications as prescribed can one hope to obtain the anticipated results This added point may seem trivial to some, but one may also expect much better results from medication prescribed with an air of confidence than from that given with a skeptical attitude that almost dares the patient to get well

I should not like to be set down as an obstinate reactionary, intolerant of all that is new Certainly the sulfonamide compounds, antibiotics,

15	56	F	Secretary	1 mo	1 yr	Hands, forearms, neck, right upper eyelid	Basic "nonallergenic" diet, diet diary	1 Food allergy	Oranges, grapefruit, wheat, coffee(?), eggs(?), pineapple(?)	Prominent psychogenic factor
16	56	F	Secretary	10 yr	6 mo	Right upper eyelid, right postauricular area	Spot elimination diet, diet diary	1 Food allergy	Chocolate, lobster, clams, crab	Exacerbations following ingestion of food, accompanied with nausea and gastrointestinal pain
17	22	F	Salesgirl	11 yr	8 mo	Hands	Scratch test-negative diet, diet diary	1 Food allergy	Cheese, pimento, pork pecans	The only patient in our series for whom a scratch test-negative diet was successful, happened to result in the elimination of all causative foods
18	12	M	Student	3 mo	1 yr	Posterior surface of neck	Spot elimination diet, diet diary	1 Food allergy	Chocolate	Repeated exacerbations on addition of chocolate to diet, after six months patient able to eat chocolate occasionally without exacerbation
19	52	M	Executive	6 mo	8 mo	Hands	Basic elimination diet, diet diary	1 Food allergy 2 Pyogenic infection	Rice	Clearing of bacterial infection along with improvement of dermatitis, without specific antibacterial therapy
20	21	F	Secretary	15 mo	6 mo	Hands, right cheek	Basic elimination diet, diet diary	1 Food allergy	Milk, wheat	Repeated sharp exacerbations on addition of milk or wheat products to the diet
21	40	M	Clerk	4 yr	6 mo	Hands	Hospitalization, strict trial diet, diet diary	1 Food allergy 2 Pyogenic infection and pyogenic sensitization	Chocolate, peanut butter	Incomplete clearing until pyogenic factor had been treated with parenterally administered penicillin and fever therapy
22	39	F	Housewife	4 yr	2 yr	Hands, feet	Hospitalization, strict trial diet, diet diary	1 Food allergy 2 Pyogenic infection and pyogenic sensitization 3 Contactant	Pepper, cinnamon, chicken, bacon, smoked ham, onions, paprika	Persistence of sensitivity to causative foods for as long as eighteen months after clearing of eruption
23	28	F	Secretary	3 yr	1 yr	Face	Hospitalization, strict trial diet, diet diary	1 Food allergy 2 Drug	Rice, butter, sweet potatoes, carrots, tomatoes, oranges, eggs, chocolate	Eczematous and folliculopustular lesions, repeated exacerbations after ingestion of vitamin B complex capsules
24	20	F	Nurse	2½ yr	2 yr	Left axilla	Hospitalization, strict trial diet, diet diary	1 Food allergy 2 Contactant	Oranges, grapefruit	Eruption resembling a fixed drug eruption
25	12	M	Physician	3½ yr	6 mo	Hands	Hospitalization, strict trial diet, diet diary	1 Food allergy 2 Contactant 3 Drug	Tomatoes, oranges, grapefruit	Phenobarbital, both as contactant and ingestant, one of the etiologic factors
26	28	M	Foundry worker	3 yr	9 mo	Hands, ankles	Hospitalization, strict trial diet, diet diary	1 Food allergy	Pork, milk, potatoes	Onset of dermatitis, on the dorsal surface of the hands, as a contact dermatitis due to a primary irritant, persistence for years (five) and complete disappearance on elimination of causative foods, repeated exacerbations demonstrated on addition of responsible foods, flare ups within fifteen to thirty minutes after ingestion of causative food

antihistaminic agents and other new drugs have opened new roads to hope in the treatment of many diseases hitherto serious in their prognosis In many instances more progress can be made in hours with the use of new drugs than was possible in months with old-fashioned treatment The risk of sensitization and toxicity inherent in many of these drugs makes it prudent, however, that they be used only when they are needed Not only dermatologists, but also physicians lacking dermatologic training, have tended too much in recent years to try these new drugs as the first medication in the treatment of all dermatoses before turning to older drugs that have proved adequate Furthermore, because of the vital importance of sulfonamide compounds and antibiotics in the treatment of dangerous infectious diseases, it is imperative that these drugs be reserved, if possible, for exigencies when they are desperately needed We dermatologists are seldom called on to treat diseases so serious as to warrant the risk of exhausting a patient's capacity for using a drug that might in the future prove to be life saving

A dissertation on good dermatologic therapy utilizing well established drugs would be incomplete if it failed to stress the most important requisites for obtaining good therapeutic results, namely the correct diagnosis of the disease and the proper appraisal of the stage of activity present One must recognize, for example, not merely that he is dealing with a tineal infection of the feet before instituting proper treatment, it is just as important for one to ascertain whether therapy should be actively fungicidal, in the chronic stage of the disease, or merely soothing, when the skin is acutely inflamed It is important for the physician to recognize the clinical picture of overtreatment dermatitis that may be masking the features of the original dermatosis Discontinuing all previous medication in such cases and the cautious use of soothing treatment will often give the patient great relief and may also bring to light the diagnostic features present One should, in addition, always keep in mind that he is treating a patient with a cutaneous disorder rather than merely treating a cutaneous disease All of us need constant reminding that the skin is often a window to internal disease A dermatologist's diagnostic eye and therapeutic acumen should encompass not only the skin but also the patient living within it

Finally, a clinical dermatologist's chief function (and most of us are primarily clinicians) is to bring to his patients relief from suffering To this end he should utilize all measures of established merit that apply to each case For this vocation most of us are well trained It has become popular in recent years, however, for many dermatologists to become clinical investigators for every new drug and proprietary mixture that is brought to market For this highly critical function most of us are not adequately equipped Not many have a large enough

an interval during which the patient had had 3 cups, there was a sharp, distinct, relatively severe exacerbation, characterized by intense pruritus and recurrence of erythema, vesiculation and oozing Within a brief period evidence of secondary bacterial infection was noted After this episode, 50,000 units of penicillin every three hours was administered for five days, during which time there was a slow but continued improvement At the end of two weeks of hospitalization, the eczematous dermatitis was less active than at any other time since the patient had come under our observation There were no vesicles or pustules, and the pruritus had almost disappeared However, there was some residual scaling, erythema and superficial fissuring The patient was discharged from the hospital, with instructions to follow a diet consisting only of baked potato, lamb and string beans

4 Continued improvement was noted during the next seven weeks except for significant exacerbations following the trial addition of tea and dried apricots to the patient's diet During this time, the diet had been increased to include beef, lamb, string beans, sugar, chicken, turkey, lettuce, asparagus, carrots, baked potatoes, canned pears, prunes, apples, eggs, white bread, saltines, vanilla ice cream, milk and ginger ale All these foods had been added gradually, one at a time, with approximately two to three days between each addition No attempt was made to add further foods during the next month, and during this time the lesions on the hands and eyelids cleared up completely

5 In the next six weeks, in the same manner, the patient added cottage cheese, American cheese, almonds, corned beef, bananas and cherry gelatin, without any exacerbations During this same period she had prompt exacerbations manifested by pruritus, erythema and a few tiny vesicles at previously involved sites, four hours after the addition of broccoli and cauliflower to her diet on two separate occasions

6 During the next six weeks the patient continued to remain free of any signs of involvement except for a slight exacerbation twelve hours after the addition of cabbage and canned peaches to her diet on two separate occasions In the meantime she had added celery, onions, green pepper, mushrooms, beets, mashed turnips, beef and calf liver and several types of fish, so that at this time the only foods restricted from her diet were tea, dried apricots, broccoli, peaches, cauliflower and cabbage

7 During the past year she has been free of involvement and has been able to do all her own housework with no effort to protect her hands from excessive contact with soap and water and other cleansing agents

It is interesting to note that tea has been the main beverage of this patient throughout her adult life because she does not like coffee and, furthermore, that she has always eaten dried apricots

The diagnosis was eczematous dermatitis of the hands, left lower eyelid, axilla and groins, with food allergy (tea, apricots, broccoli, cauliflower, cabbage, and peaches), pyogenic infection and pyogenic sensitization as factors

Comment This is an example of a difficult food allergy problem It is probable that this patient would have been included in the group of those in whom treatment was a failure or, rather, that the food allergy factor would not have been recognizable if it had not been possible for her to be hospitalized and if her cooperation had not been unusually good It may be noted that this patient reacted to several members of the cabbage family, as well as to related fruits She is the only patient in our entire series for whom tea was recognized as a food allergen

A Case for Diagnosis (Mycosis Fungoides? Psoriasis?) Presented by DR JAMES R WEBSTER, DR SAMUEL BLUEFARB and (by invitation) DR N BAKER

Superficial Epithelioma on Sacral Area with Basal Epithelioma near the Anus Presented by DR THEODORE CORNBLEET and (by invitation) DR D COHEN and DR J GRAFFIN

A Case for Diagnosis (Acrodermatitis Chronicus Atrophicans) Presented by DR MICHAEL H EBERT and (by invitation) DR M S KAGEN

Nodular Leukemia Cutis in a 14 Month Old Boy, Duration Eight Months Presented by DR MICHAEL H EBERT and (by invitation) DR N L BAKER

Syringocystoma Presented by DR MICHAEL H EBERT and (by invitation) DR N BAKER

Francis W Lynch, M D, *President*

Leonard F Weber, M D, *Secretary*

June 18, 1947

Adenoma Sebaceum Presented by DR T CORNBLEET and (by invitation) DR H SCHORR and DR J GRAFFIN

R S, a Negro woman aged 23, as a child had frequent episodes of "spasms" which may have been epileptic-like in nature She finished the seventh grade in school at the age of 19 years, and she works as a dishwasher

On May 22, 1947, she entered a medical ward at Cook County Hospital with acute rheumatic fever Subsequently, she had a spontaneous pneumothorax, which is gradually disappearing

Examination reveals an eruption limited to the face which is predominantly on the central portion, chin and eyelids The lesions consist of dark brown papular nodules varying from a few millimeters to 1 cm Neurologic examination revealed no abnormalities Fundoscopic examination has not yet been completed

The Kahn reaction of the blood was negative Urinalysis showed albumin (1 plus) The examination of the blood showed hemoglobin 66 per cent, erythrocytes 3,530,000, leukocytes 5,600, with a normal differential count, and nonprotein nitrogen 22 mg per hundred cubic centimeters The sedimentation rate was 40 mm per hour

The roentgenogram of the chest originally showed a left total pneumothorax, at present there is a 30 per cent residue The roentgenogram of the ankles showed no abnormalities The histologic section from a nodule of the cheek is presented

DISCUSSION

DR M R CARO I agree with the diagnosis both clinically and histologically Histologic examination showed a fibromatous type of tumor rather than hyperplasia of sebaceous glands

DR ROBERT M B MACKENNA, London, England (by invitation) It was clearly shown in this case that the lesions are not present to any great degree

on the upper lid Epithelioma adenoides often attacks the upper lid, and adenoma sebaceum spares it

Contrast Sweating Above and Below Line of Paraplegia Presented by Dr T Cornbleet, Dr H Schorr and Dr N L Baker

H C, a Negro aged 25, was a patient at the Hines veterans' hospital from March 6, 1946 to January 1947 He complained of pain in the right leg and in the lower thoracic part of the spine, of four years' duration A laminectomy was done May 26, 1946, and a lesion was encountered at the level of the ninth thoracic vertebra which appeared to be an intramedullary cord tumor He was transferred to the Cook County Hospital Jan 20, 1947, where he complained of profuse sweating of the entire upper half of the body Injections of atropine sulfate afforded relief for two to three hours

Physical examination showed complete flaccid paralysis of the lower extremities Pain and pressure sense are diminished on the lower part of the abdomen and lower extremities There is no profuse sweating of the face, neck, upper extremities or trunk There are follicular keratoses of the sternum and other areas on the trunk

The urine contained albumin (1 plus) and many white blood cells The Kahn reaction of the blood was negative, and the blood cell count was normal The spinal fluid contained 330 cells per cubic millimeter, and the protein was 3,500 mg per hundred cubic centimeters

A roentgenogram taken after injection of opaque material indicated a complete block at the level of the ninth thoracic vertebra

DISCUSSION

Dr Stephen Rothman This is a good example of hyperhidrosis of organic central nervous system origin On the patient's back there are beginning signs of prickly heat, showing that softening of the horny layer and plugging of the pores occur in hyperhidrosis irrespective of whether it is peripheral or central in origin

Dr Theodore Cornbleet The patient presents all the changes in some areas that have been described for miliaria induced by heat Above the point of laminectomy and paraplegia there is excessive sweating, below there is excessive dryness The plugging of sweat pores and the changes that follow in miliaria are here reduplicated Thus it is excessive sweating itself which leads to cornification at the sweat duct orifices Heat is not necessary for the production of the syndrome, except in so far as it stimulates increased sweating

A Case for Diagnosis (Seborrheic Dermatitis) Presented by Dr Theodore Cornbleet and (by invitation) Dr D Cohen and Dr N L Baker

Cutaneous Blastomycosis, Therapeutic Result Presented by Dr F E Senear and staff

W S C, aged 57, was referred to the Department of Dermatology, Illinois Research and Educational Hospitals, in October 1946 with the diagnosis of blastomycosis, proved by biopsy Examination revealed an irregularly circinate plaque at the left commissure of the mouth, extending laterally on the cheek for about 8 cm The lesion was sharply marginated and had a precipitous border and a mammillated, somewhat elevated, crusted surface A few microabscesses were visible in the border, and the central portion of the lesion had healed, leaving a fine pinkish scar

CASE 2—B M, a nurse aged 29, had first noted approximately one year previously what was described as a pruritic, vesicular patch of dermatitis on the dorsal surface of her left hand It had occurred approximately ten hours after she had mixed penicillin solution, during which procedure a moderate amount of the concentrated solution had come into contact with the affected site During the next three months she had had several recurrences of pruritic, vesicular dermatitis on the dorsal surface of the hand, with complete remission between these episodes After this period, she had had more frequent attacks, as well as extension of involvement to the dorsal surface and sides of several fingers Furthermore, the lesions persisted between attacks, and at times superficial fissuring, which interfered with the movement of her fingers, occurred

Six months after the initial onset, all lesions cleared up completely during a three weeks' vacation, when the patient was away from her work as a clinic nurse There was prompt recurrence when she returned to work At this time she consulted a dermatologist, who found positive reactions to patch tests with penicillin, contact with this drug was discontinued There was slight improvement, but complete clearing did not occur, and the patient continued to have periodic exacer-

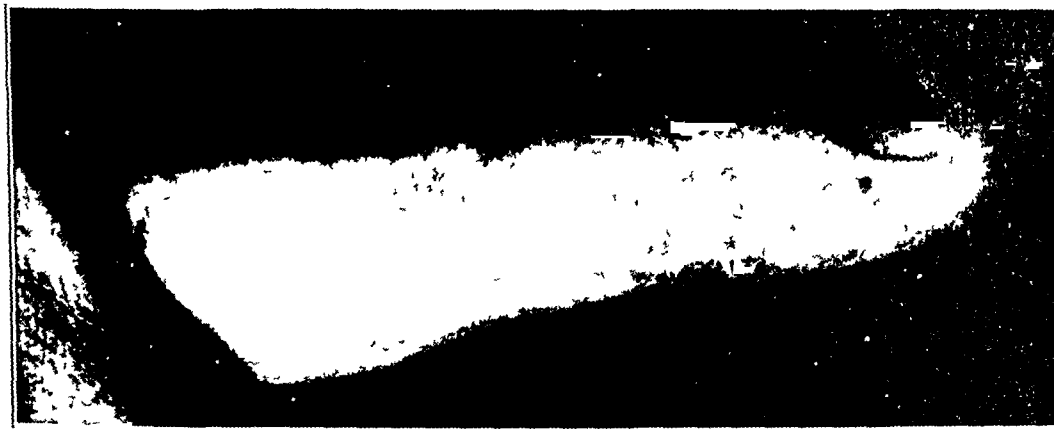

FIG 1 (case 2) —One of the eczematous plaques on the fingers, which on one occasion flared up simultaneously with the exacerbation of a lesion on the eyelid

bations Patch-testing was then done with procaine hydrochloride (novocain®) and streptomycin, with positive results, and therefore contact with these drugs was discontinued However, despite this action, during the next three months the patient continued to have repeated flare-ups, and finally it was necessary for her to discontinue her work for the second time Within one week, there was significant improvement, but she continued to have new vesicles and also had one distinct, rather severe exacerbation which was certainly not related to contact with penicillin, procaine hydrochloride or streptomycin At the time of the exacerbation she consulted an allergist, who confirmed the previously reported positive reactions to patch tests and also demonstrated that she had pronounced sensitivity to trichophytin, for this reason he advised a series of injections with trichophytin as an attempt at desensitization Because of financial reasons, it was essential for her to return to work There was no improvement, and indeed the severity and extent of her lesions gradually increased during the next two months, the exacerbations were not related to the injections of trichophytin

Other treatment included strict avoidance of soap and water, with use of a soap substitute, superficial roentgen therapy and application of several unidentified ointments

characteristic in that they are fairly well demarcated, erythematous, edematous and slightly scaling and in many respects resemble a fixed drug eruption

Individual lesions vary considerably In the vast majority of patients there is a vesicular element, although vesiculation may be absent There is a tendency to oozing and superficial fissuring, and in many persons vesicopustules and other signs of secondary pyogenic infections are dominant when the patient is first seen In general, the borders of plaques are not well demarcated, and they are not annular with a tendency to central clearing Pruritus, which is usually intense, is a regular feature of eczematous dermatitis due to food allergy The itching is periodic and varies from day to day unless one of the causative foods is eaten daily

When food diaries are used as a method of study, pruritus is almost as dependable as a sign of an exacerbation as is the appearance of new vesicles and other objective evidence

However, unfortunately, there are no absolute diagnostic criteria in distinguishing eczematous dermatitis due to food allergy from that due to other factors, but with experience it is possible for one to acquire a "high index of suspicion"

COURSE OF ECZEMATOUS DERMATITIS DUE TO FOOD ALLERGY

In most cases there is a history of a tendency to spontaneous exacerbations and partial remissions We have not been particularly impressed with a change of incidence in relation to the season of the year, although in general the process tends to be severer during the winter months

Quite uniformly, rapid, significant improvement has been noted in one to three days when the causative foods were eliminated, provided that the etiologic picture was not complicated by other factors, such as contactants and pyogenic infection Exacerbations which follow addition of an allergenic food have occurred within fifteen minutes after a small serving of a particular food, and, almost always, objective evidence of such exacerbations is preceded by pruritus On the other hand, the interval between ingestion and exacerbation has been as long as forty-eight hours after the food was eaten, and in 3 of our patients exacerbations did not occur until the food had been eaten on six consecutive days It seems quite certain that exacerbations occur more promptly and with a smaller quantity of the allergenic food if the addition to the diet is made within a few days after the initial lesions have become quiescent Many patients have been observed in whom decided prompt exacerbations occurred after ingestion of a given food soon after initial improvement had occurred on a trial diet, several weeks or months later, these same patients failed to have such exacerbations following the addition of the same food to the diet It would

When the patient consulted us, she had seven distinct, rather well demarcated, erythematous, oozing, scaling, vesicular plaques on the dorsal surface and sides of three fingers of the right hand, two fingers of the left hand and the right palm There was some crusting but no frank vesicopustules In addition, she had superficial fissures in several plaques, and there was some limitation of movment of the involved fingers The only other finding of importance was an erythematous, edematous, scaling, well demarcated plaque on the inner surface of the right upper eyelid The latter lesion had been noted about two weeks previously

Fig 2 (case 22) —The exacerbation which is illustrated followed the ingestion of smoked pork Concomitant bacterial infection was a complicating factor

The familial and personal allergic history were noncontributory except that the patient had had what had been diagnosed as allergic vasorhinitis on one occasion when she was living in Texas There was no history of any type of previous cutaneous disease or intolerance to any contactants encountered during her work as a nurse prior to the onset of her present trouble

The management and course of this patient's eczematous dermatitis during the seven months' observation period were as follows

1 She was advised to discontinue work, which she did for a three week period, and during this time Dr Norman Ingraham Jr did a complete allergy work-up,

seem that in many instances spontaneous desensitization takes place, and several months after disappearance of the patient's dermatitis foods which caused definite exacerbations previously may be taken without resultant symptoms or signs in the skin

Our experience is at variance with that of Rowe [7b] in that we believe that significant improvement is evident within several days to one week, provided that all the allergenic foods are eliminated from the diet and provided that all other contributory factors have been eliminated and treated Those patients who have other etiologic factors in addition to food allergy will not improve significantly on a therapeutic approach which is designed to find and eliminate only the food allergy factor

It is our opinion that the process in many of these patients had its onset as allergic contact dermatitis, and in others as a primary pyogenic dermatitis, for example Later on in the course of the disease, the specific food sensitivity factor became operative and in many instances became the chief perpetuating factor in the eruption Also, the reverse was true in that in some instances the eruption had its onset as an eczematous dermatitis due to foods and subsequently other factors, such as allergic contactants, invasion and sensitization by bacteria, complicated the process As in allergic contactant dermatitis it is advantageous for one to treat eczematous dermatitis due to food allergy early in the course of the disease because it is easier to effect a cure under these circumstances This point was well illustrated in many of our cases

INCIDENCE OF SENSITIVITY TO VARIOUS FOODS

This series of patients is too small for analysis as to the relative frequency with which individual foods may sensitize the skin, but it is interesting to tabulate the results for what they are worth In 1 or more patients the allergenic role of the following foods was demonstrated in our series of 26 patients, and in almost all instances exacerbations were noted on 2 or more occasions

Food	No of Patients	Food	No of Patients
Chocolate	9	Grapefruit	5
Sea food *	8	Tomatoes	4
Wheat	6	Eggs	4
Oranges	6	Broccoli	2
Pork	5	Rice	2
Milk	5	Cinnamon	2
Nuts	5	Smoked pork	2

* Lobster, 2, crab, 2, shrimp, 2, clams, 1, and shad, 1

Specific sensitivity to the following foods was encountered in 1 patient peaches, carrots, onions, peas, Scotch whisky, butter, veal, pepper, cauliflower, pimento, coffee, pineapple, tea, apricots, cabbage,

a summary of which follows Reactions to patch tests were negative for a long list of household and other contactants except for crystalline penicillin G (1 cc containing 25,000 units), 3 plus, a 2 per cent aqueous solution of procaine hydrochloride, 3 plus, and o'cedar® furniture polish (50 per cent in olive oil), 3 plus Scratch and intradermal tests with aqueous protein extracts of common dust-borne allergens, except for those with mixed feathers, sheep dander, rabbit hair and cow dander, had negative reactions Scratch tests with 140 foods had negative results except for weakly to moderately positive reactions to almonds, bananas, lima beans, Roquefort cheese, cherry, chicory, cinnamon, coconut, dates, grapefruit, milk, mustard, onions and poppy seed

2 She had about a 50 per cent improvement during the three week period when she was away from work, but she continued to have exacerbations characterized by intense pruritus and the appearance of new vesicles, particularly at the periphery of the involved sites At times, the eyelid lesion flared up concomitantly with the

Fig 3 (case 22) —This site of involvement had flare-ups on numerous occasions when one of the responsible food allergens was added to the diet The lesions on the patient's hand are illustrated in figure 2

lesions on her hands, but at other times either the eyelid lesion or the hand lesions flared up independently The only local treatment which was used consisted of aluminum acetate solution (1 20) soaks several times daily, followed by application of 3 per cent itchthammol in zinc oxide ointment After the allergy work-up, o'cedar® furniture polish was added to the list of contactants for her to avoid, and also the patient was asked to follow a diet consisting of only the foods which gave entirely negative reactions on scratch tests She returned to work, inasmuch as the severity of the exacerbations and their frequency during the time when she was away from work were such that the financial sacrifice did not seem justifiable

3 There was no significant improvement on a scratch test–negative diet during the next three week period, and therefore chocolate, coffee, orange, cheese and tomato and nuts were also eliminated from the diet, in addition, the patient was asked to keep a careful diet diary Wheat and eggs were not added to the list

string beans, lima beans, chicken, sweet corn, vanilla extract, rye, sweet potatoes, cheese, paprika and white potatoes At the present time another patient, for whom the primary food allergen is beef, is under observation, as is another, for whom canned pears are the most important food allergen

COMMENT

It should be emphasized particularly that, while allergic sensitivity to foods is an important reason for chronicity and persistence of an eczematous eruption, it is not an etiologic factor for even a majority of such patients, and study and treatment of the patient in this regard must be carried out with scrupulous regard for the many other possible etiologic factors concerned In addition, as with many other methods of treatment, too great enthusiasm or "faddism" for diets may have a medically deleterious effect on the whole patient Prolonged restriction of caloric intake, particularly for underweight patients, for many growing children or for the aged is obviously unjustified Likewise, the balance of various fractions in the diet and the adequacy of vitamin intake must receive thoughtful consideration Some patients will cooperate too enthusiastically for their general medical good and may continue to follow severely restricted diets for too long a time and with too little justification

In general, local treatment was not particularly helpful in the management of this series of cases, except in those in which bacterial infection was an important contributory factor Also, superficial roentgen ray therapy does not seem to influence significantly the course of eczematous dermatitis due to food allergy More than 50 per cent of our 26 patients had had an adequate trial of roentgen ray treatment, and, although apparent partial initial improvement had been noted in some patients, the end result was unsatisfactory in all cases in that relapse occurred within a short time after the treatment was discontinued Penicillin administered parenterally was useful in controlling pyogenic infection when this was a complicating factor

The history in regard to food sensitivities and other allergic manifestations prior to the onset of the presenting dermatitis was not particularly helpful in the initial evaluation of these patients There was a family history of allergy for 15 per cent of the patients and a personal allergic (not atopic dermatitis) history for 15 per cent, although the two groups were not identical

The psychogenic factor seemed to be important for several of our patients, and indeed our experience with the present series leads us to believe that there is an emotional component in the background of the vast majority of persons with food sensitivities For this reason, one must be careful to evaluate each patient critically and include in the

of foods to be eliminated at this time because it is most difficult for one to avoid these foods in a hospital dining room

4 The patient had some improvement in her condition in the next two weeks, but continued to have periodic flare-ups, although they were less severe than previously At this time wheat was added to the foods to be eliminated from the diet

5 There was no change in the next week, and at this time it was decided to add eggs to the interdicted foods, which action meant that the total restriction of the diet included the elimination of almonds, bananas, lima beans, Roquefort cheese, cherries, cinnamon, chicory, coconut, dates, grapefruit, milk, mustard, onion and poppy seed, which had been eliminated on the basis of positive reactions to scratch testing, and chocolate, coffee, orange, cheese, tomatoes, nuts, wheat and eggs, which had been eliminated in an effort to obtain a so-called basic nonallergenic diet

6 During the next two weeks, after the elimination of eggs from the diet, there was more sustained improvement than at any previous time since the patient had come under our observation, and for the first time there was complete absence of pruritus and no appearance of new vesicles within the last week

7 Five days later the patient had a distinct flare-up at all previously involved sites, including the eyelid, characterized by pruritus, vesiculation, oozing, erythema and edema This exacerbation occurred approximately six hours after she had eaten one boiled egg It subsided entirely within five days

8 After this development, the patient remained free of symptoms and lesions except for four exacerbations, all of which subsided promptly The first such exacerbation did not occur until she had eaten one egg daily for three days, the second, until she had eaten one egg daily for six days, and the third, until after she had increased her intake of milk to one quart daily for three consecutive days During the next six weeks all other interdicted foods were added, without any exacerbation, so that, at the end of this time, the restriction of her diet included only the elimination of eggs and the limitation of milk to one glass daily, with no restriction of foods containing milk

9 During the next three months her hands and eyelid remained clear, despite the addition of all foods containing eggs to her diet, although she continued to restrict eggs to three weekly (one every other morning for breakfast) She had continued to work as a nurse and had done all her own housework, with avoidance of furniture polish, procaine hydrochloride, penicillin and streptomycin, but with no other restrictions or precautions

The diagnosis was eczematous dermatitis of the hand and left eyelid, due to allergic contactants (penicillin, streptomycin, procaine hydrochloride and o'cedar® furniture polish) and food allergy (eggs and milk)

Comment It seems apparent that this patient originally had an allergic contact eczematous dermatitis and that the food allergy factor did not enter the picture until approximately six months after the onset of her dermatitis, which gradually increased in severity, presumably because of repeated exposure to the allergic contactants It is obvious that the responsible foods would have been discovered promptly if this patient had been hospitalized or if a resrticted elimination diet had been put into effect early in our observation period When egg was added to the diet one week after pronounced improvement had occurred, a

group of persons with food allergy only those patients who have definite repeated exacerbations following the addition of causative foods to the basic diet It is conceivable that at least some of these patients could be cured with ideal psychiatric treatment, but this approach has had limited usefulness in our experience This principle was illustrated in the case of 1 patient who had repeated exacerbations of her dermatitis after the ingestion of small quantities of grapefruit during a period of considerable emotional strain incident to working under an exacting employer, some months later, under more favorable circumstances of employment, it was possible for her to eat several times as much grapefruit with only minimal pruritus and very few objective signs of involvement

It is essential for one to realize that there is an appreciable individual variation in the course of patients who have eczematous dermatitis entirely or in part due to specific food sensitivity In some cases a prompt regression of the dermatitis is noted after the interdiction of the responsible foods, in others significant improvement does not occur for as long as seven to ten days The same variation applies to the onset of an exacerbation following the addition of a causative food, although in the vast majority of cases such exacerbations are seen within a period of forty-eight hours It is not a simple procedure to manage the patients successfully, and considerable experience is necessary before one acquires an appreciation of the problems involved The physician who follows a stereotyped approach will not cure a significant percentage of patients with cutaneous food allergy

SUMMARY AND CONCLUSIONS

1 A series of 26 patients with eczematous dermatitis, for whom it was demonstrated that specific sensitivity to various foods was the only etiologic factor or a significant contributory factor, is presented

2 The chief localization site encountered was the hands (involved in 81 per cent), although the feet, eyelids, legs, arms, face, scrotum, groins, neck, buttocks, perianal region and axillas were also involved in 1 or more of our patients

3 In addition to food allergy, other concomitant etiologic factors, including allergic contactants, primary irritants, pyogenic infection and pyogenic sensitization and allergic drug factors, were demonstrated for 12, or 46 per cent, of these 26 patients

4 Eczematous dermatitis due to food allergy tends to occur in localized, rather inflammatory plaques, oozing, vesiculation and excoriations were noted in a high percentage of cases Apparent spontaneous exacerbations and partial remissions are relatively common

5 Pruritis, which was usually quite severe, was a regular and prominent feature of the process

flare-up ensued within a short time after the ingestion of only one egg, six weeks after the lesions had become quiescent, a flare-up did not occur until the patient had eaten one egg daily for six consecutive days, several months later, she was able to eat three eggs weekly, as well as foods containing eggs, without any return of pruritus or objective signs This spontaneous desensitization is a common sequence of events, provided that all causes of the eczematous dermatitis have been eliminated and the lesions have remained entirely clear for several weeks to several months It may be noted that she had a negative reaction to a scratch test with the only significant food allergen which was one of the proved causative factors

Fig 4 (case 11) —The patient also had large, oozing, eczematous plaques on both legs Numerous exacerbations such as the one illustrated were demonstrated on the addition of wheat and chocolate to the diet

Case 3—H H, a secretary aged 36, was referred to us because of an unusually severe, patchy, eczematous dermatitis of the feet and hands, with maximal involvement of the feet, which had been present for fifteen months This was characterized by scaling, erythematous, superficially denuded, crusted, vesicular, fissured plaques on the inner surface of the right foot, extending from the instep to the dorsal surface of the foot and involving part of the ankle, the dorsal surface of the right foot at the base of the first interdigital space and extending into the interdigital space, the instep of the left foot and the medial surface of the left foot just above the heel The borders of the lesions were not well demarcated, only a few vesicles were seen In addition, there was a faintly erythematous, rather well demarcated, dry, slightly lichenified plaque on each palm, as well as a few superficial vesicles along the sides of several fingers All lesions tended to be dry, scaly and somewhat lichenified rather than oozing, although there was some exudation at several sites on the feet

6 Scratch tests with foods were of almost no value in the management of these patients

7 The methods of approach in the study of these patients are discussed in some detail Ideally, the vast majority should be hospitalized for an adequate evaluation from the standpoint of food allergy, for about 40 per cent of our patients such evaluation would not have been possible without hospitalization However, with a fair percentage of cooperative patients, satisfactory elimination diets can be put into effect on an outpatient basis, especially if food allergy is the only etiologic factor involved

8 The necessity of evaluating and treating such patients along broad etiologic lines as well as with respect to food allergy is emphasized and illustrated in the case histories of many of our patients

9 Chocolate, oranges, wheat, pork, eggs, sea food, tomatoes, grapefruit, nuts and milk were encountered more frequently as food allergens in this series of patients, but specific food sensitivity was demonstrated to twenty-six other foods by one or more patients Sensitivity to two or more foods was demonstrated by 24 of the 26 patients

10 It is believed that food allergy is one of the important etiologic factors in eczematous dermatitis In our experience, food allergy is the only etiologic factor or a significant contributory factor in the case of 16 to 18 per cent of patients with chronic eczematous dermatitis of the hands and/or feet

11 The technic of management and interpretation of results are relatively difficult, especially in the cases of those patients for whom food allergy is only one of numerous possible etiologic factors

ABSTRACT OF DISCUSSION

DR SAMUEL M PECK, New York I wish to congratulate Dr Livingood for the fine piece of work which he did and especially for his patience in carrying out this type of rather ungrateful research The average dermatologist is somewhat prone to disregard the value of the approach which Dr Livingood has made because, on the one hand, it is so time consuming and, on the other, the results in many instances are most disappointing I think the chief difficulty in this problem is the fact that one is unable to judge on clinical evidence alone which cases are due to foods and which are due to the many other factors which can give the same clinical syndrome Also, it is very rare to have a factor such as food sensitivity play other than a major or a minor role in the dermatitis Food plays a role in infancy and childhood as the sole cause of eczema This point no one will deny However, it is difficult for many to visualize a dermatitis which is limited to the hands as being mainly due to a food factor Certainly, in the eczema of infancy and childhood, one rarely, if ever, sees limited localization, especially as far as the hands are concerned It would be a great help if there

This condition had had its onset as a rather small, coin-shaped, pruritic, scaling, eczematous plaque on the inner surface of the right foot, approximately fifteen months before the patient consulted us Soon afterward, there had been progressive extension and increase of pruritus, which was intense and occurred in paroxysms The course had been characterized by repeated exacerbation and partial remission, but complete clearing had not occurred at any time, and pruritus had not been absent for more than one or two days at a time The patient had been under the care of a radiologist, who had given her approximately fifteen roentgen ray treatments, during which course of therapy she had had partial improvement and one lesion which had appeared on the flexor surface of the wrist had disappeared

Fig 5 (case 24) —In some respects case 24 was one of the most interesting in our series despite the apparent insignificance of the involvement The lesion resembled a fixed drug eruption It had persisted for almost three years and disappeared within seven days after the responsible food allergens were eliminated Numerous prompt exacerbations were demonstrated on the addition of food allergens to the diet

entirely She had received a total of 1,500 r to all affected sites Soon after the roentgen ray treatments were discontinued, there had been progressive increase of involvement, and for this reason the radiologist had referred her to us The management and the course of her eczematous dermatitis during the twelve month period of observation were as follows

1 Hospitalization was strongly advised, but this was not possible All previous local medication, which had been quite varied, was discontinued, and 3 per cent

were a simple approach to establish or rule out foods as etiologic factors I have attempted to find one in many instances, but so far, the necessary procedure still boils down to the tedious, long-drawn-out, trial and error type of approach One thing should be emphasized, namely, that, as I believe, in different parts of the country and probably among different classes of population different combinations of factors are responsible for the dermatitis on the hands In the few cases in which I believe I have definitely established food allergy as a cause of eruptions on the hands, nearly all the patients were females If this observation is common, I think it should be helpful Furthermore, when a patient with a dermatitis on the hands presents himself or herself to me, I automatically lean away from consideration of food as an etiologic factor in the dermatitis of the hands in men, for them fungi, bacteria and contact factors are the predominating etiologic agents In women, bacteria or molds will also play a role if the eruption is present long enough I should like to cite 1 case which to me was enough payment in satisfaction and compensated for all the failures with this approach This was of a young married woman who came to me with a dermatitis of the hands of months' duration I automatically went through the routine procedures of looking for an infectious agent and for household contacts as the cause of her dermatitis I totally disregarded the fact that I had treated her successfully for food allergies as the cause of her infantile eczema In looking over her old records, I found mention of this, and when she eliminated the foods to which she had again become sensitive over the years, the dermatitis on her hands finally cleared up One must bear in mind that, even when the offending foods are removed, there is no dramatic improvement Patience and a thorough understanding of all the factors which contribute to the dermatitis are all needed in order for one to treat one of these patients successfully I wish to congratulate Dr Livingood and Dr Pillsbury for an excellent paper

Dr Earl D Osborne, Buffalo I, too, wish to congratulate Dr Livingood and Dr Pillsbury on having cured anyone with a condition having a food factor in an allergic background It is a very difficult job to undertake There are a few observations I should like to make First, I do not believe that it has been proved that protein substances as such will produce eczematous reactions When one speaks of foods, one must realize that one is talking about a very chemically complex subject Foods contain not only proteins but also fats, carbohydrates and a multiplicity of oleoresins I should like to ask Dr Livingood whether he did any patch testing in his cases with oleoresins present in the various foods It appears to me that it is possible for one to explain many apparent recurring vesicular eruptions of the hands on the basis of the ingestion of specific oleoresins present in various foods It is known that in the case of poison ivy and other weed dermatoses a flare-up of a preexisting eruption on any part of the body can be produced by the ingestion of the specific or related oleoresin concerned I believe that specific hypersensitivity does exist to the oleoresins in many fruits and vegetables, both from local contact and, in recurrences following this, from the ingestion of the specific oleoresin Finally, it is my belief that investigation will show that when foods are at fault in the production of an eczematous eruption the responsibility is probably that of the oleoresin content and not of the protein, carbohydrate or fat content of the particular food

Dr Eugene F Traub, New York I, too, enjoyed Dr Livingood's presentation and wish to thank him I should like to ask him several questions Were the cases in which the condition appeared to be influenced by or to react to certain foods discovered through the use of test diets, or did the patients react positively to tests with food to which they were not otherwise known to be sensitive? What

ichthammol in zinc ointment was prescribed A summary of an allergy work-up, done by Dr Norman Ingraham Jr, follows

A Patch tests of a wide variety of contactants, including eight different constituents of her shoes, and nylons, had entirely negative reactions

B Reactions to scratch and intradermal tests with common dust-borne allergens were completely negative

C A number of sharply positive reactions to scratch tests with foods were obtained, and it was Dr Ingraham's opinion that these were of a type which would

Fig 6 (case 4) —There was an important contributory pyogenic factor in this patient's eruption, and evaluation of the food allergy factor was not possible until the bacterial infection was treated concomitantly

make one feel that they could be of significance The foods producing positive reactions were almonds, apples, asparagus, bananas, beets, broccoli, carrots, cashew nuts, cauliflower, American cheese, Roquefort cheese, cherries, cinnamon, coconut, coffee, dates, dill, eggplant, lemons, mushrooms, oats, oranges, peanuts, white potatoes, prunes, spinach, turkey, watercress and wheat During this two week period there was no restriction of the patient's diet and no improvment

2 Within one week after she was placed on a scratch test–negative diet, there was 75 per cent improvement in all lesions, with decrease of pruritus Two weeks

was the percentage of cases in which skin tests with food were helpful? Did any adults in the series that were found to be sensitive to food give any history of having been previously sensitive to that particular food, or had they always enjoyed that food in the past? How long did this newly discovered food sensitivity last? Was it permanent, or did it clear up after the other factors had been removed?

DR MARION SULZBERGER, New York I wish to compliment Dr Livingood and Dr Pillsbury on an excellent paper The first point I should like to emphasize is that no one who has not attempted to carry out exact diets on ambulatory patients can realize how difficult the task is My own results with this method in the last fifteen years have been on the whole very unsatisfactory I should like to point out that it is almost prohibitively difficult for the patient to carry out a rigid elimination diet While on such diets the patient can join in almost no social activities—no eating out, no lunches while away from home, no participation in meals with others and no snack or candy or drink between meals, for example I have found that under these conditions patients either make involuntary slips or keep cheating The second point I should like to stress is that it is now obvious that atopic dermatitis has an eczematous phase This is true, not only in infants but in adults, although in the latter it is not as uncommon This form of atopic eczematous eruption may, of course, be susceptible to flare-ups following exposure to allergenic foods, just as are some cases of infantile eczema And in adults atopic eczematous eruptions can and do appear on the hands, particularly the dorsa of the fingers

Did Dr Livingood exclude the external contact with foods? It is difficult for one to eat bread or oranges, for example, without letting them touch the hands I think that in order to come to the conclusions that these eruptions are due to ingestion of foods, one must always and absolutely exclude the possibility of external contact, and I feel certain Dr Livingood has done this

I enjoyed the presentation and should like to suggest that Dr Livingood and Dr Pillsbury may in the future find it advantageous to attempt to classify their cases of "hand eczemas" into two large groups, namely, those of nonatopic and atopic dermatoses

My impression is that the results following elimination of certain foods would be much greater in atopic persons than in the nonatopic ones Moreover, for reasons which I mentioned in discussing aberrations of sweating, the role of foods and drugs in exacerbations of dyshidrosis may merit careful scrutiny in the future

DR CLARENCE S LIVINGOOD, Philadelphia I wish to thank the discussers Many of the questions brought up in these discussions are answered in our paper In answer to the questions of Drs Sulzberger and Osborn, with reference to external contact with food, rather than ingestion, as a factor We had thought of that point, and it has been our experience that eczematous lesions in some cases are caused by contactant sensitivity to foods, especially citrus fruits and vegetables However, in our series of cases, external sensitization to foods was a minor factor in comparison with endogenous allergy to foods We have been careful in evaluating this particular question, and, for example, in some cases suspected foods were given in capsule form

The duration of sensitivity to a particular food or foods varies in individual cases In some of our cases the sensitivity disappeared within several weeks after the lesions had disappeared, in others repeated exacerbations could be reproduced as long as six to eight months after the involution of the eruption, and in some it is probable that the sensitivity persists indefinitely We agree with Dr Peck that the allergic pattern in regard to food sensitivity in a given case is likely to change over a period of years

later, there was no additional improvement Therefore, she was asked to try for one week a basic "nonallergenic" diet consisting only of apricots, peaches, canned pears, prunes, sugar, tea, beans, chicken, string beans, lamb, lettuce, cabbage, peas, ry-crisp,® corn bread, salt, sweet potatoes, turnips, peach preserves and apricot preserves After one week on this diet, she had complete relief of pruritus and all signs of involvement, except for residual hyperpigmentation, scaling and very slight lichenification, had disappeared

3 At this time, she went on vacation and disregarded her diet entirely On successive days, she ate sea food dinners and chocolate candy—indeed, there was no interdiction of foods Within twelve hours after the first such meal, there was pronounced recurrence of pruritus, followed by a sharp, severe exacerbation involving all previously affected sites During the next three weeks, she resumed her scratch test–negative diet except that chocolate, nuts and all sea foods were added to the interdicted foods The pruritus disappeared within three days, and regression of objective signs gradually occurred except for one exacerbation possibly associated with the ingestion of watermelon At the end of three weeks, the patient was free from pruritus, and only residual hyperpigmentation and slight scaling persisted at the previously involved sites

4 During the past eight months, this patient noted repeated exacerbations following the attempted addition of the following foods to her diet wheat bread, or wheat flour in any form, chocolate, shrimp, crab meat, lobster and coffee In the last three months, she has been able to drink an occasional cup of coffee without exacerbation except for transient pruritus She has found that complete elimination of wheat products for a period of two or three weeks, as well as interdiction of chocolate, shrimp, crab, lobster and coffee, is followed by complete absence of all signs of involvement Furthermore, if the ingestion of wheat products is limited to two pieces of part rye and part wheat bread daily, pruritus and scaling of previously affected sites are so minimal that they do not interfere with any of her activities, therefore, she prefers to accept these consequences rather than eliminate bread entirely Repeated attempts to increase the amount of wheat-containing foods resulted in decided increase of pruritus of the eczematous patches at approximately the original sites of involvement

The diagnosis was eczematous dermatitis, due to food allergy (wheat, chocolate, coffee, shrimp, crab and lobster), of the hands and feet

Comment The initial elimination diet, which was based on scratch test–negative foods, happened to exclude the principal food allergen, which was wheat, and, also, it resulted in the interdiction of coffee, which was a relatively unimportant food allergen Complete improvement did not occur on this dietary regimen because of other specific food sensitivities in the form of several different sea foods and chocolate, all of which produced negative reactions in scratch tests Complete relief of symptoms and disappearance of pruritus followed a brief period of pronounced dietary restriction, which happened to exclude all the responsible food allergens It is probable that this patient could have been cured by a brief period of hospitalization and the use of a strict trial diet The rapid response to interdiction of foods would have made it possible to add foods rather rapidly, and within one month she could have been placed on a quite adequate diet

TRAUMATIC MARGINAL ALOPECIA IN WHITE WOMEN

SAMUEL AYRES Jr, M D
SAMUEL AYRES III, M D
AND
JOSEPH I MIROVICH, M D
LOS ANGELES

COSTA and Junqueira[1] recently summarized the literature on traumatic marginal alopecia, which, according to their observations and those of Ribeiro,[2] occurs almost exclusively in Negro and mulatto women They pointed out the similarity between this condition and alopecia liminaris frontalis as described by Sabouraud[3] and expressed the opinion that both conditions are caused by stretching the hair in tight braids or "buns" and, especially in the case of Negro women, by efforts to straighten kinky hair Folliculitis frequently results from this constant traction, and, with or without folliculitis, atrophic changes of the follicles gradually develop and lead to permanent alopecia

In the cases described by Ribeiro and by Costa and Junqueira the alopecia occurred in triangular areas involving the temples, with the apex pointing downward in front of the ears

Inasmuch as the previously reported cases of this entity occurred exclusively in Negro or mulatto women, except for 1 case in a white woman, mentioned by Ribeiro, it seemed worth while to record 5 cases in white women

In view of the fact that the alopecia tends to be permanent if the trauma due to traction from tight hairdress or excessive brushing is allowed to continue, it becomes important for one to recognize the

SUMMARY STUDY AND TREATMENT OF PATIENTS

The successful study and treatment of these 26 patients from the food allergy point of view was accomplished by the following methods (1) strict trial diet including hospitalization, for 11 patients, (2) basic "nonallergic" diet, for 9 patients, (3) "spot" elimination diet, for 5 patients, and (4) scratch test–negative diet, for 1 patient

Furthermore, attention to other factors, including careful study and elimination of contactants and primary irritants, elimination of the use of drugs (internal) in several patients, and treatment of the pyogenic factor, was necessary in 12 of the 26 patients Cure was obtained in only 54 per cent of these 26 patients by determination and elimination of the responsible food allergens alone

At the same time, it is emphasized that food allergy was such an important contributory factor in the disorders of the other 46 per cent of the patients in whom it was not the only etiologic factor that a satisfactory therapeutic result could not have been accomplished without the discovery and elimination of the allergic foods

From these data, it would seem that any single dietary method of approach, without consideration of other factors, will result in misconception with regard to the possible primary or contributory food sensitivity factor, and resultant therapeutic failure In those patients in whom a food sensitivity is the only etiologic factor, prompt improvement and a clinical cure will follow the institution of a suitable elimination diet We agree with Flood and Perry that the strict trial diet will result in the highest percentage of cures, but the basic nonallergenic diet which we have used on an outpatient basis will be effective for a significant number of patients for whom food allergy is the only etiologic factor The so-called "spot elimination diet," which simply provides for the interdiction of a small number of foods of high allergenic index, will effect a cure in a fairly small percentage of patients The failure of any particular dietary regimen tends to discourage the patient and makes it difficult for one to institute a more rigid dietary approach In general, it is preferable for one to outline a diet which informs the patient what he is to eat, rather than one which tells him what he is not to eat In the other large group of patients, in whom food sensitivity is only a contributory concomitant factor of varying importance, study and treatment is much less rewarding therapeutically, without hospitalization, it is most difficult for one to untangle and treat the multiple etiologic factors involved

INCIDENCE OF FOOD ALLERGY IN ETIOLOGY OF ECZEMATOUS DERMATITIS

It is difficult for one to evaluate accurately the role of food allergy in the etiology of eczematous dermatitis so far as the exact incidence is concerned In the first place, it is not possible for one to exclude food

entity and to advise regarding corrective measures After atrophy of the follicles has taken place no method of treatment would be likely to succeed If the causative factors are eliminated early enough, complete recovery takes place, according to the aforementioned observers

REPORT OF CASES

CASE 1—D H, a girl aged 18, came in primarily for the treatment of acne of a moderate degree of activity In addition to the acne examination revealed a pronounced thinning of the hair along the sides of the scalp above the ears, where the hair was pulled up toward the top of the head in tight braids Scattered through the areas of partial alopecia were a number of small follicular papulopustules

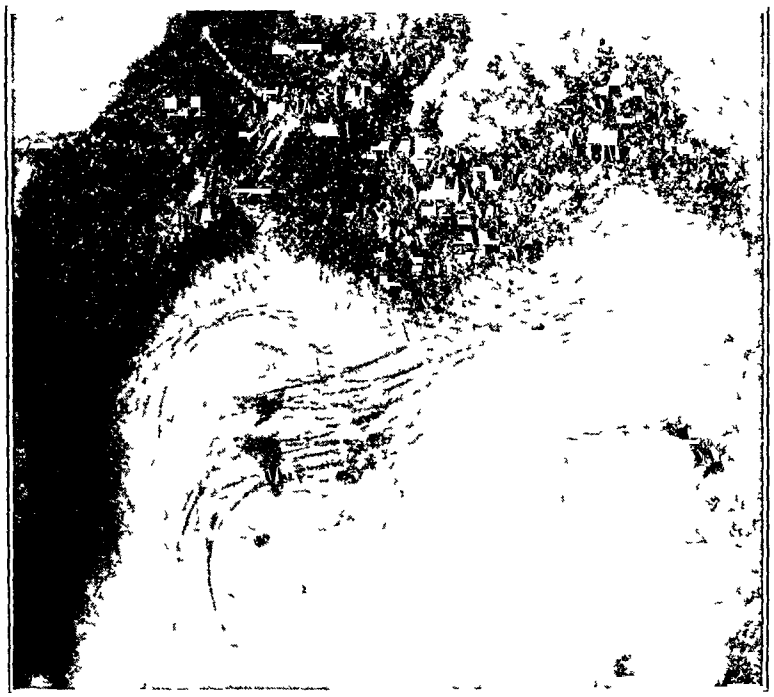

FIG 1 (case 1)—Area of alopecia in front of and above ear, due to constant traction from tight braids

CASE 2—A C, a girl aged 18, came to the office primarily for the treatment of redness, crusting and slight swelling of the eyelid margins, characteristic of blepharitis Examination revealed, in addition to the condition of the eyelids, a moderate degree of thinning of the hair on both temple areas in front of the ears There were a number of broken hairs, some of them with an exclamation point appearance, and a few follicular pustules scattered through these areas The patient had been in the habit of using metal curlers on the sides of her scalp for the preceding four months She thought that the thinning of the hair was of about six weeks' duration

CASE 3—E W, a woman aged 65, presented herself with a complaint of an eruption on the sides of the scalp, associated with a thinning of the hair which had been present for about six months The patient had been using metal curlers at night

allergy as an etiologic factor in a given case unless the patient is hospitalized and placed on a strict trial diet and unless there is the elimination of other possible contributory factors, such as pyogenic infection and contactants, which might obscure a concomitant food sensitivity Obviously, such a procedure is not feasible in a fair percentage of cases Furthermore, the experience of various investigators will differ considerably For example, physicians in industry will encounter a higher incidence of eczematous dermatitis due to allergic contactant and primary irritant factors It has been our experience that food allergy is the only significant etiologic factor for about 7 to 8 per cent of the patients with chronic eczematous dermatitis and an important contributory factor for an additional 8 to 10 per cent of such patients The common concomitant factors which were recognized in the present series of 26 patients include allergic contactant, primary irritant, pyogenic infection and sensitization and drug allergy

DESCRIPTION OF LESIONS

We agree with Sulzberger that if food allergens cause eczematous eruptions of the hands "then foods must be considered as possible etiologic agents in other eczematous eruptions no matter what their localization", and it has been our experience that such eruptions due to specific food sensitivity do occur at other sites on the cutaneous surface

We have recorded the following sites of involvement in one or more patients all surfaces of the hands and feet, the eyelids, the forearms, the upper arms, the legs, the thighs, the face, the neck, the groins, the posterior surface of the scrotum, the axillas, the external auditory canals, the trunk and the buttocks It is true that the hand is the site of predilection, but this is certainly not the only site of localization In our series of cases, the hands were involved in 21 of 26 patients, the dermatitis was limited to the hands with no other involved sites in only 10 of the 26 patients

Eczematous dermatitis due to food allergy tends to be patchy rather than diffuse The dorsal surface and sides of the fingers, the palms, the dorsal surface of the hands and the interdigital spaces occasionally have been sites of localization which we have noted on the hands On the feet, the patches tend to be localized on the inner and dorsal surfaces of the feet, although the distribution may be on the dorsal surface of the toes, suggesting an allergic contact dermatitis, or on the plantar surface of the feet, suggesting dermatophytosis Usually the involvement is in the form of plaques, although patients with diffuse involvement of the axillas and groins, as well as with diffuse involvement of the extremities, have been observed The eyelid lesions are quite

Examination revealed a diffuse thinning of the hair over the scalp, with a mild seborrheal scaling Involving each temple area in front of the ears there was a more pronounced loss of hair, with a few broken hairs and empty follicles Just above this area on both sides was a transverse erythematous and slightly elevated ridge or streak which the patient stated coincided with the area covered by the metal curlers There were a few follicular papules in this erythematous area A patch test with the patient's aluminum curler gave no reaction

CASE 4—D H, a girl aged 11, had noticed thinning of the hair, with irritation along the temples, for about two weeks The patient had been in the habit of rolling her hair tightly with metal curlers at night and had been spending a great deal of time every day brushing her hair upward along the sides

Examination revealed a moderate degree of thinning of the hair along the temples in front of and just above the ears There were a number of broken

FIG 2 (case 3)—Triangular area of alopecia involving the temporal region in front of the ear due to constant traction from the use of tight curlers

hairs, one of which was shaped like an exclamation point There was also a moderate degree of redness on each side of the scalp and a number of small superficial papules, several of which were crusted A patch test was made with nickel, but the patient did not return for observation

CASE 5—E J S, a woman aged 30, had had a scalp disorder for one and a half years The patient had been in the habit of combing and brushing the hair upward from the sides and fastening it in a tight braid

Examination revealed an appreciable thinning of the hair, with some erythema, over the temporal regions Some of the empty follicles showed dark plugs, and there was evidence of atrophy throughout the areas

Roentgen irradiation, in a total dose of 2,085 r, has been administered, along with potassium iodide orally in a maximum daily dose of 90 minims (about 6 cc) The lesion has cleared except for four small crusted areas at the periphery

Blastomycosis Presented by DR EDWARD A OLIVER and DR J M MCCUSKEY

The patient is a dairy operator and handles powdered milk The lesions appeared about four weeks ago

At present there are twelve nodular lesions on the face and the back of the neck, varying in size from that of a split pea to that of a hazelnut The lesions are erythematous, boggy and studded with pinpoint to pinhead-sized yellow pustules, especially at the periphery On the right hand, there is a deep, erythematous, indurated mass, the size of a hen's egg

Microscopic examination of material from the periphery of the lesions showed Blastomyces

DISCUSSION OF PREVIOUS TWO CASES

DR OLIVER S ORMSBY Years ago, when we had foreign guests, it was possible within a short period to bring in several patients with blastomycosis for demonstration Such cases are now comparatively rare There was a time when I had 100 cultures grown from 100 different patients Dr MacKenna can get no idea about what blastomycosis looks like by seeing the patients presented today One patient was cured with efficient treatment, and the other did not have typical lesions The skin lesions in a typical case are classic They occur in plaques with elevated margins and a superficial smooth scar in the center The margin of the lesion slopes and contains true abscesses in which Blastomyces are found The cases of systemic disease are different My co-workers and I had the privilege of reporting the first one in 1903, in which the lesions were clinically and symptomatically blastomycosis The lesions in that case consisted of subcutaneous abscesses, ulcerations and nodules We proved that the skin lesions came by way of the circulation At that time a large number of patients with systemic blastomycosis died—at least 50 per cent of the patients with systemic disease died The course was like that of severe pellagra some years ago I was in London when the disease was being discussed in this country, and the London men were much interested It was not until 1907, when many physicians from abroad were here to attend the international congress, that we were able to demonstrate to our foreign guests that blastomycosis was an entity—they thought it was syphilis I am sorry that Dr MacKenna did not see an example of the American variety of the disease

DR STEPHEN ROTHMAN We will have the opportunity to demonstrate a case of extensive American blastomycosis to Dr MacKenna tomorrow in Billings Hospital Dr Senear's patient has shown remarkable response to therapy In cases with widespread lesions the initial therapeutic effect of iodides is always impressive, but it takes years for them to clear up The lesions heal rapidly in the center but spread peripherally The supporting effect of local roentgen irradiations is rather modest Local application of fungicides is ineffective, in spite of their fair fungicidal action on Blastomyces in vitro We have not seen any beneficial effect of vaccine therapy Apparently cases with small simple lesions are easier to manage

DR. M J REUTER, Milwaukee In Dr Senear's case there is still some activity around the borders of the lesions In resistant plaques such as this, I

have been destroying the lesion with diathermy, at the same time giving the patient large doses of potassium iodide by mouth

DR THEODORE CORNBLEET The surgeons think that the dermatologists' approach to the treatment of cutaneous blastomycosis with medical measures is inadequate, inefficient and a loss of time They believe, at least some of them, that the lesions should be excised and the defects grafted They believe that even large areas are better treated with such a direct attack Their view is that as long as the disease is superficial breadth of area involved is a secondary consideration

DR FRED BECKER, Duluth, Minn Some investigators have expressed the belief that, prior to iodide therapy for systemic blastomycosis, a cutaneous test with a Blastomyces vaccine should be performed If the result is positive, it denotes allergy and desensitization must be performed, with gradually increasing doses of the vaccine until this positive cutaneous sensitivity is eliminated Then only should iodine therapy be instituted They cited several cases in which giving iodides produced rather disastrous results in a patient highly sensitive to the vaccine

DR STEPHEN ROTHMAN I understood that vaccine was required as initial therapy in cases with hypersensitivity to iodides and that the vaccine therapy was supposed to desensitize to iodides I wonder whether these observations have been corroborated In our case with no iodide sensitivity, vaccine therapy had no effect whatsoever although the patient shows strongly positive cutaneous reactions to the vaccine

DR ADOLPH ROSTENBERG JR (by invitation) I have had no firsthand experience treating blastomycosis As I understand Conant and his colleagues, a patient with systemic involvement who is allergic to a blastomycosis vaccine may have a spread of the blastomycosis if he is given iodides If the vaccine is given first some kind of immunity develops, so that the patient is subsequently able to take iodides The present immunologic point of view regarding diseases such as blastomycosis has altered considerably Primarily through the work of Dr Rich at Johns Hopkins Hospital it has been realized that there is dissociation between so-called immune phases and the hypersensitive phases of a disease and not, as originally stated, that hypersensitivity is a way station on the road to immunity This makes it questionable whether anything is accomplished from the point of view of immunity by desensitization in the tuberculin type of sensitization Possibly one succeeds only in abolishing or reducing the skin reaction

DR F E SENEAR Dr Ormsby recommended that arsphenamine therapy be employed when patients who had been receiving iodides for blastomycosis failed to show further progress and that after this procedure, with the use of but a few injections, the blastomycosis would again become responsive to iodide therapy

While I believe that American blastomycosis is not seen as frequently now as in the past, there has been a change in the clinical appearance of this disorder My co-workers and I have recently seen several patients with cutaneous manifestations from systemic blastomycosis, and in these instances a considerable number of widely scattered lesions have developed spontaneously About three years ago, I had, in the space of four months, 3 patients in this category The organism is readily demonstrable in lesions of this type We have also seen in recent years a larger number of patients with the deep-seated furunculoid, or cold abscess, type of lesion

SUMMARY

Five cases are reported of traumatic marginal alopecia in white women

The clinical appearance consists of a triangular area of partial alopecia involving the sides of the scalp above or in front of the ears, usually accompanied by folliculitis and atrophy of the follicles

The condition is believed to be caused by persistent traction on the hair from vigorous and prolonged brushing, a tight hairdress or the use of curlers Previously reported cases of this condition have occurred in Negroes or mulattoes

2007 Wilshire Boulevard (5)

5 T gypseum was identified as the etiologic agent in about two thirds of the cases of tinea pedis yielding cultures and in about 60 per cent of the cases of tinea unguium yielding cultures T rubrum was identified as the etiologic agent in two thirds of the cases of tinea cruris and tinea manus

6 Correlation of types of lesion with species of fungus has been most successful in cases of tinea pedis and tinea unguium Six types of lesions were noted in each

7 The search for multiple clinical types should be painstaking, since the detection of the type aids not only in ultimate eradication but also in the clinical identification of the etiologic agent

8 Statistics indicate that it is the etiologic agent rather than the type of lesion which influences the possibility of isolation T gypseum is easier to isolate than is T rubrum

SUPERFICIAL MYCOSES OF VETERANS

II Dermatophytosis and Cutaneous Moniliasis, Correlation of Clinical Manifestations and Etiologic Agent

R C BURKE, Ph D
CAMBRIDGE, MASS
AND
F E BUMGARNER, M D
LOS ANGELES

IN THE past few years several efforts have been made to correlate the fungus species with the clinical manifestations of the superficial mycoses Among these studies have been the work of Lewis, Montgomery and Hopper [1] on the clinical manifestations of Trichophyton purpureum and that of Montgomery and Caspar [2] on the clinical manifestations of Tricophyton purpureum, T gypseum and Candida albicans

In a previous paper,[3] we reported on a study of 1,000 veterans with in-service diagnoses of superficial mycoses, 466 of whom had fungous infections as proved by laboratory examination Of these, 416, or 87 1 per cent, showed dermatophytosis, and 13 (3 per cent), moniliasis The 416 patients with dermatophytosis and 13 with cutaneous moniliasis had 819 clinical manifestations of various types of dermatophytosis, falling into the commonly recognized categories of tinea pedis, tinea unguium, tinea cruris, tinea manus and generalized tinea, in that order of incidence

Slides and cultures were made in each case in an attempt to correlate the various types of lesions with the etiologic agents In general this correlation was most successful with tinea pedis and with tinea unguium In tinea manus, in contrast, only slight correlation could be

SARCOMA INVOLVING THE SKIN

ERVIN EPSTEIN, M D
OAKLAND, CALIF

TRADITIONALLY tumors have been divided into those of ectodermal and those of mesodermal origin The malignant neoplasms have been similarly divided into carcinoma, including melanoma, and sarcoma However, this classification is not completely satisfactory, since in some cases epithelioma, especially melanoma, reacts in the body in the same highly malignant manner as sarcoma Furthermore, in some cases sarcoma—in many of the cases neurosarcoma—is actually of ectodermal origin However, common usage makes this classification the most workable at this time

A voluminous literature has developed around the problems presented by cases of cutaneous epithelioma and melanoma While sarcoma is not completely neglected, comparatively little can be found in dermatologic writings concerning it Beerman,[1] in his excellent review on tumors of the skin, did not find enough to enable him to consider sarcoma Yet the dermatologist is often called on to diagnose and eradicate the smaller sarcomatous lesions As will be demonstrated later, sarcoma is among the most difficult to diagnose in the field of cutaneous neoplasms Furthermore, as in the case of epithelioma, cure depends on early recognition of the growth and prompt, adequate therapy

MATERIAL

The statements made in this paper are based on a study of 28 patients with histologically proved sarcoma involving the skin Six of the patients were encountered in private practice The remainder were studied from records made available by cooperating physicians and hospitals [2] In this series all of the neoplasms except 1, diagnosed as rhabdomyosarcoma, are believed to have originated in the skin and its appendages Cases of special types of sarcoma, well recognized by

From the Departments of Dermatology, Highland-Alameda County Hospital, Oakland, and Mount Zion Hospital, San Francisco

made, while in tinea cruris, unfortunately, no dependable correlation could be found The results of study will be discussed for each category, in the following order tinea pedis, tinea unguium, tinea cruris, tinea manus and generalized tinea

TINEA PEDIS

Of the 360 positive cases of tinea pedis, a fungus was isolated in 186, or 51 per cent T gypseum was cultured in 118 cases (63 per cent), Trichophyton rubrum in 58 cases (31 per cent), Epidermophyton floccosum in 4 cases (2 per cent) and C albicans in 6 cases (3 per cent) In other words, T gypseum was encountered about twice as frequently as was T rubrum, and both E floccosum and C albicans were rarely found If only the three dermatophytes are considered, T gypseum was isolated in 64 per cent of the cases, T rubrum in 34 per cent and E floccosum in 2 per cent

The latter figures agree favorably with those of the results obtained by Miss Rhoda Benham, as detailed by Hopkins and associates,[5] who credited her with 111 positive cultures for the periods of 1940 and 1946 The incidence of T gypseum obtained by Benham averaged 64 per cent, that of T rubrum, 25 per cent, and that of E floccosum, 5 per cent Percentages obtained by Lewis and Hopper[6] in 1938 for 153 cultures were not dissimilar T gypseum, 73 per cent, T rubrum, 25 per cent, and E floccosum, 2 per cent

Six types of lesions were identified in cases of tinea pedis chronic intertriginous, chronic hyperkeratotic scaling, chronic papulovesiculosquamous, bullous, subacute and severe chronic hyperkeratotic scaling Table 1 details the total number of cases of each of these types, the percentage in which cultures were obtained and the percentage of each of the etiologic agents

Chronic intertriginous lesions accounted for 41 7 per cent of the 360 clinical cases noted Cultures were obtained from 48 per cent of the cases In this type of lesion it is almost impossible to determine the etiologic agent by clinical examination alone T gypseum was isolated in 54 3 per cent, T rubrum, in 36 per cent, and E floccosum and C albicans, in 1 4 per cent and 8 3 per cent, respectively

Chronic hyperkeratotic scaling lesions of the plantar and medial surfaces ranked second, comprising 19 per cent of the 360 cases Cultures were obtained in only 37 1 per cent of the cases, the majority

each instance Combined infection with T rubrum was recorded in 2 instances

Only 14 (5 per cent) subacute lesions (mycosis plus secondary infection) were proved to be tineal Antibacterial treatment was administered to some patients before positive cultures were obtained Cultures were obtained in 57 1 per cent of the cases, T gypseum being identified in 87 5 per cent Subacute lesions were of vesicular or bullous origin

Severe chronic hyperkeratotic scaling was noted in only 4 cases (0 1 per cent), from 3 of which cultures yielded E floccosum It was necessary to reculture material from 2 of these cases before the organism was obtained

One may reason that it is possible to identify the etiologic agent by clinical examination alone in the case of bullous and severe chronic hyperkeratotic scaling lesions—that is, T gypseum in the first instance

dermatologists, as Kaposi's sarcoma and lymphosarcoma, were not included in this study Table 1 presents the 28 cases included in the series

CLINICAL PICTURE

Sarcoma develops in the skin or the subcutaneous tissue as a small nodule If superficially located, it grossly resembles epithelioma Growth may be rapid or slow, although the former is more common The nodule develops to form a mass which becomes elevated, discolored (usually purplish) and later necrotic and ulcerated Bleeding is common Later, the necrotic ulcer becomes fungating and granulomatous Involvement of regional lymph nodes is comparatively infrequent, this having been noted clinically in only 2 cases (7 1 per cent)

Only a single tumor was present in 24 cases (86 per cent) Multiple tumors were found in the other 4 Table 2 gives the location of these tumors There were 61 lesions in the 28 patients The most important finding is that in 39 4 per cent of the cases the lower extremities were

TABLE 2.—*Location of Tumors in this Series*

Location	Cases
Head	6
Trunk	10
Upper extremities	3
Lower extremities	11

involved In 35 8 per cent the trunk was affected Sarcoma was noted on the thighs in 28 6 per cent Epithelioma is definitely unusual in these locations

CLINICAL DIAGNOSIS

Sarcoma is easily diagnosed from its clinical appearance when it has become a massive purplish tumor with necrosis, ulceration and fungating overgrowth However, in no instance in this series was the clinical diagnosis suggested on simple inspection of a small growth The clinical diagnoses in 18 cases in which a tentative diagnosis was offered prior to surgical intervention are given in table 3 In the 3 instances in which the tumor was correctly diagnosed, the lesion was far advanced In the personally observed 6 cases the diagnosis was sarcoma in 1 (a large necrotic mass), squamous cell epithelioma in 1, basal cell epithelioma in 2, granuloma pyogenicum in 1 and fibroma in 1 The only other common diagnosis in the other 22 cases was infectious granuloma, including cutaneous tuberculosis, in 3 cases Therefore, the most important differential problem is that of epithelioma The coincident, adjacent occurrence of epithelioma and sarcoma in 2 cases further complicated the problem of diagnosis

and E floccosum in the second Of the chronic papulovesiculosquamous lesions, T gypseum was the etiologic agent in three fourths and T rubrum in the others Four fifths of the subacute lesions may be assumed to be caused by T gypseum It is not possible to identify by clinical examination alone the fungous species in chronic intertriginous lesions

In addition to the foregoing conclusions, one may infer from the material in table 1 that T rubrum is more difficult to isolate than is T gypseum In the five types of tinea pedis due to species of Trichophyton, the greater the percentage of lesions from which the organism was isolated, the higher the incidence of T gypseum noted For instance, cultures from bullous lesions yielded the etiologic agent in 74 per cent of lesions, T gypseum being isolated in each case, while cultures from chronic hyperkeratotic scaling lesions yielded the agents in only 37 1 per cent of all lesions, T gypseum being noted in 15 4 per cent and T rubrum in 84 6 per cent One may infer that the incidence of T rubrum would be much higher in the case of chronic hyperkeratotic, chronic papulovesiculosquamous and chronic intertriginous scaling, and even subacute lesions, if cultures were obtained from all cases listed

TINEA UNGUIUM

Among the 429 cases of dermatophytosis, there were 245 cases of tinea unguium, of which 222 cases were of infected toe nails and 23 of infected finger nails Infection of the toe nails was noted and proved by laboratory examination in 60 per cent of the cases of tinea pedis Hopkins and associates [5] had observed infected toe nails in 47 per cent of their cases of recurrent tinea pedis

At first, the number of nails involved and the degree of involvement were believed to be of primary importance, but it soon became apparent that there was some correlation between the organism isolated and certain types of involvement of the nail Therefore considerable effort was expended in an attempt to obtain a reliable key which could be used by physicians interested in this problem It is not felt that this key is a complete answer, but it is believed that it forms a basis for future and more exhaustive study

As in cases of tinea pedis, six types of lesions have been noted in cases of tinea unguium, the last two types have been observed only on the hands

Type 1 Leukonychia trichophytica, consisting of white patches on the surface or within the nail plate T gypseum has been reported as the agent always isolated, however, the mycology laboratory isolated T rubrum in 3 out of 5 cases in which cultures were obtained

Table 4 outlines the differential points between sarcoma and epithelioma The most important features may be briefly mentioned Of the cases of sarcoma, 35 8 per cent occur in the precancer age The most common locations for sarcoma are on the extremities and the trunk, areas comparatively infrequently involved by epithelioma The massive growth and necrosis usually make the differentiation obvious Sarcoma is more frequent in Negroes than is epithelioma, and this may be of importance in some cases Sarcoma usually grows more rapidly than epithelioma The lesions of both sarcoma and epithelioma are usually single but may be multiple in either case Sarcoma often develops in

TABLE 3.—*Preoperative Diagnosis in 18 Cases of Sarcoma Involving the Skin*

Diagnosis	Cases	Diagnosis	Cases

TABLE 4.—*Differential Diagnosis Between Sarcoma and Epithelioma*

Differential Point	Sarcoma	Epithelioma
Age	35 per cent less than 40	Usually over 40
Location	Trunk and lower extremities	Face and dorsa of hands
Clinical picture	Massive overgrowth	Ulceration
Negroes	More frequent	Less frequent
Growth	More rapid	Slower
Onset	Cutaneous or subcutaneous	Cutaneous
Surgical findings (gross)	Necrosis, greater spread than expected	Nodular and ulcerative
Metastases	Common	Comparatively infrequent
Lymph node involvement in presence of metastases	Infrequent	Probably always

the subcutaneous tissue, although it commonly appears in the true skin originally

While simple inspection and palpation may not establish the correct diagnosis, two features are found at surgical intervention that give one invaluable clues to the true nature of the neoplasm Even in small size, sarcoma extends more deeply than one would expect epithelioma of the same apparent size to do and second necrosis is present These features have been of great importance in this series

ETIOLOGY AND INCIDENCE

Obviously, the cause of sarcoma is unknown However, there are certain known factors of interest For instance certain precarcinomatous lesions may also be presarcomatous In this group might be included

TYPE 2 Inverted V infection, with pronounced symmetry, little if any epithelial debris and dulness of the nails (particularly if hyperhidrosis is associated) Usually all the nails on one or both feet are involved T gypseum is isolated in the majority of cases

TYPE 3 Asymmetric infection, with epithelial debris, thickened nail plate, infected nail bed and involvement of from 1 to 10 nails If the nails are in the same stage of involvement and, if the nails, particularly those on the second to fifth digits, are dull, T gypseum is the organism most frequently isolated If the nails are in varying stages of involvement and retain some luster, T rubrum is the fungus most often isolated

TYPE 4 —Ragged, opaque, thick and crumbly nails Both T rubrum (in the majority of the cases) and T gypseum have been isolated from such nails Often various saprophytes are also present In 1 instance, mycelium and conidia of Hormodendrum were noted throughout the nail tissue Several plates were planted with scrapings from the nail, and T gypseum and Hormodendrum sp were both isolated

TYPE 5 Nail uninfected, separated from infected nail bed T gypseum was isolated in 1 case, while in 5 other cases the agent was not obtained This type of lesion was noted only on the hands

TYPE 6 —Transverse ridges in nails which are frequently dull or opaque, with a serous exudate at times and occasional paronychia This is the well known C albicans type of lesion

It was possible to culture the organism from toe nails in 33 per cent and from the finger nails in 56 per cent of the cases The figure given for the toe nails is lower than that obtained in similar studies by Lewis and Hopper, as communicated to one of us (R C B) Final results of the study disclosed that of the 429 patients having dermatophytosis or cutaneous moniliasis, 245, or 57 per cent, had some degree of involvement of the nails All these, with the exception of 18, showed concurrent involvement of the feet or other parts of the body

Kittredge [7] stated that generalized involvement of all the nails was unusual and that the case he reported at the time was the seventh one to be reported Such occurrences, however, are not as unusual as the paucity of literature on the subject would indicate Three such cases, in all of which T rubrum was yielded, were uncovered among the veterans included in this study In addition, 11 cases of tinea unguium of all the toe nails due to T rubrum were recorded In 7 of these 11 cases the patient had acquired the infection in Alabama, Mississippi or Louisiana and presented not only type 3 involvement of all the nails

7 Kittredge, H E Onychomycosis Universalis Trichophytina et Epidermophyta Report of Seventh Case Thus Far Recorded in English, Arch Dermat & Syph **34** 398 (Sept) 1936

lupus vulgaris, xeroderma pigmentosum and radiodermatitis MacKee[3] and others have stated that it is doubtful that sarcoma ever develops in areas of radiodermatitis While cases have been reported in which a lesion developing in such an area histologically resembled sarcoma, he felt that it was actually of epithelial origin In case 2 of this series a lesion diagnosed as sarcoma developed less than 1 inch (2 5 cm) from a lesion diagnosed as squamous cell epithelioma in an area of radiodermatitis The former was of greater duration than the latter, but both lesions were present at the same time and were excised in a single block dissection Histologically there was no resemblance between the two lesions After a study of special stains (Masson's, silver impregnation and phosphotungstic acid) Biskind[4] felt that the sarcomatous lesion was of mesodermal origin[4a] In case 13 three lesions were removed from the face of a 77 year old man at the same time Histopathologic examination revealed that one lesion was basal cell epithelioma, one was mixed cell epithelioma and the third sarcoma

Six apparently unrelated conditions occurred concurrently with sarcoma in this series Four psoriasis, lupus erythematosus, polyarthritis and cholelithiasis—were obviously coincidental, and each occurred in 1 case only Tuberculosis was noted twice Sarcoma was associated with carcinoma in 3 instances This is 10 7 per cent of the entire series but is 16 6 per cent of the patients over 40 years of age, i e , in the cancer age

The evidence presented in the two previous paragraphs causes one to speculate whether the factor that leads to the development of sarcoma is not the same as that which leads to carcinomatous degeneration Apparently there is in certain patients and certain lesions a tendency toward malignant changes, and the malignant cells may be of epidermal or mesodermal origin

Trauma seemed to be important in the development of sarcoma in 5 cases, 17 8 per cent In 4 cases the patient related the onset of the tumor to a severe traumatic incident involving the affected area These included a kick in the buttocks in a fight, a home accident, an automobile accident and an industrial accident In the fifth case, apparently a recurrent low grade sarcoma of twenty years' duration became actively malignant, the growth was accelerated and death occurred two years after an automobile accident The literature is filled with arguments

3 MacKee, G M X-Rays and Radium in the Treatment of Diseases of the Skin, ed 3, Philadelphia, Lea & Febiger, 1938, p 355

4 Biskind, G Personal communication to the author

4a According to a report received from Major Robert B Franklin, Medical Corps, United States Air Force, dated July 29, 1949, this patient was hospitalized because of metastases in the left pleura and the liver Such metastases are much more suggestive of sarcoma than of epithelioma

but also concurrent chronic hyperkeratotic scaling of the plantar surfaces The strains of T rubrum isolated in these cases are being studied because of certain morphologic variations

TINEA CRURIS

Tinea cruris ranked third in prevalence, comprising 86 of the 429 cases of dermatophytosis and cutaneous moniliasis In only 18 of the 86 verified cases was the infection limited to a single site In some of these 18 cases there was a history of possible tinea pedis In 22 cases there were two lesion areas, 18 of which were of the feet and groin In the remaining 46 cases there were three or more lesion sites

Three types of lesions were noted. "eczema marginatum" type, a solid plaque type and the erythematous, exudative monilial type Correlation of the clinical aspects with the etiologic agent has not been possible in the case of tinea cruris Cultures were obtained in only 33 7 per cent (29 cases) of the verified cases Of this number, cultures yielded T gypseum in 8 (27 5 per cent), T rubrum in 16 (55 4 per cent), E floccosum in 1 (3 3 per cent) and C albicans in 4 (13 8 per cent) This small number does not provide sufficiently valid percentages, but comparison of the figures for T gypseum and T rubrum (omitting those for C albicans) indicates that, where the true dermatophytes are concerned, T rubrum is the etiologic agent in about 66 per cent of the cases of tinea cruris

TINEA MANUS

Tinea manus ranked fourth in incidence of the clinical types of dermatophytosis In all, 254 cases of service-diagnosed "ringworm of the hands" were studied Only 48 cases were established definitely as of tinea manus The majority of the cases in which this disease was not established were characterized by vesicular and exudative lesions, located particularly on the fingers

In only 10 of the positive cases were the hands alone involved, in 9 cases the feet and hands were involved, and the remaining 27 yielded three or more positive lesion sites There was a definite racial distinction observed in that only 5 Negroes (a ratio of 1 Negro to 3 white patients) were shown to have tinea manus T gypseum was recovered from lesions on the hands of 2 Negroes and T rubrum from another

With regard to origin of infection of the hand and wrist, an interesting factor was noted One third of the patients with verified lesions had a history of having worked with motor fuels and machinery at the time of onset

regarding the importance or the lack of importance of trauma in initiating malignant changes Five more cases will not settle these arguments

There were 17 men and 11 women in this series However, in other reported studies there does not seem to be any significant difference in sex incidence

Twenty-five of the patients were white, the other 3 were Negroes Apparently, the Negro does not possess immunity from sarcoma paralleling his comparative freedom from certain other types of cancer, including basal cell epithelioma Furthermore, all 3 Negroes died of their sarcoma in an average of eighteen months The longest survival in a Negro in this group was two years This is a much shorter period of survival than the average for the entire series (5 35 years)

The age at the time of onset is given in table 5 This demonstrates that no age group is exempt The youngest patient was 1½ years of age, the oldest, 80 years of age Thirty-five and seven-tenths per cent of the patients were less than 40 years old the so-called precancer age

TABLE 5—*Age at Onset of Sarcoma*

Years	Cases	Years	Cases
0 to 10	2	41 to 50	8
11 to 20	1	51 to 60	4
21 to 30	4	61 to 70	4
31 to 40	8	71 to 80	2

The 6 personally observed cases were culled from about 9,000 dermatologic cases, an incidence of 1 in 1,500 However, this incidence seems high, as I do not recall seeing sarcoma in any other group of dermatologic patients that have been under my care According to Eller,[5] primary sarcoma of the skin accounts for only 5 to 6 per cent of cases of all types of sarcoma occurring in the human body

PATHOLOGY

It is not the purpose of this paper to reiterate the well established criteria for the histologic diagnosis of sarcoma However it should be realized that despite clearcut textbook descriptions it is often difficult to establish the diagnosis of sarcoma For instance, MacKee,[3] as previously stated, claimed that the lesions arising in areas of radiodermatitis that have been diagnosed as sarcoma by general pathologists are in reality spindle cell epithelioma Montgomery [6] stated that most so-called

5 Eller, J J Tumors of the Skin Benign and Malignant, 1939, Lea & Febiger, Philadelphia, p 434

6 Montgomery, H Epithelomas of the Arm Simulating Endothelioma Sarcoma and Sporotrichosis Two Unusual Cases, M Clin North America **19** 605 (Sept) 1935

Three definite and distinct types of lesions were observed in tinea manus a chronic hyperkeratotic scaling, most frequently involving the palms and ventral surfaces of the fingers, a chronic papulovesiculosquamous eruption, which may involve the palm but which most frequently manifests itself on the dorsum of the hand and on the wrist, and a bullous type involving the palmar areas

The chronic hyperkeratotic scaling type has been observed most frequently, it was seen in 34 (65 4 per cent) of the total of 52 cases of different types of lesions Scaling is variable but usually fine and branny It was expected that T rubrum would always be isolated from this type, particularly since that was the general rule with chronic hyperkeratotic lesions of the feet However, of the 19 cases in which cultures were obtained only 14 (73 7 per cent) yielded T rubrum, the cultures in the other 5 (2 Negroes and 3 white patients) having yielded T gypseum (table 2)

TABLE 2—*Type of Lesion and Etiologic Agent in Cases of Tinea Manus*

* Four cases with both chronic hyperkeratotic scaling and chronic papulovesicular squamous lesions were observed

Chronic papulovesicular squamous lesions of the dorsum of the hand and wrist were observed in 12 cases In 9 of these, cultures were obtained In 4 the organism was identified as T gypseum and in 5 as T rubrum Several patients with this type of lesion of the hands had generalized dermatophytosis as well The bullous type of tinea manus was observed only once, on the thenar and hypothenar eminences of the left hand of a 26 year old Negro He also had bullous lesions of the feet T gypseum was identified from cultures of both areas

Of the 32 cultures made in cases of tinea manus, in 21, or 65 7 per cent, T rubrum was identified We believe that the greater part of the 44 per cent of uncultured chronic hyperkeratotic scaling lesions and of the 25 per cent of uncultured chronic papulovesicular squamous lesions were probably due to T rubrum This belief rests, in part, on evidence presented in table 1 and table 2, which indicates that T gypseum is

cases of sarcoma of the extremities are actually cases of epithelioma Furthermore, it is often difficult to determine whether a lesion is a sarcoma or very cellular, nonencapsulated benign fibroma This is well illustrated by the case reported by Eller and Kest [7] Biopsy specimens were sent to a number of leading skin and tumor pathologists The following diagnoses were offered by these admitted experts D L Satenstein and D Wilbert Sachs—"small spindle cell sarcoma with hemorrhage", Emmerich von Ham "fibrosarcoma", Hamilton Montgomery—"angiosarcoma", Paul Klemperer—"fibrosarcoma", J Frank Fraser—"fibrosarcoma", Fred D Weidman "fibrosarcoma", Francis Carter Wood—"neurofibroma" In a study of cases presented before various dermatologic societies in this country it is obvious that this is not an unusual experience

This demonstrates the difficulty of accepting histologic observations as the only proof of the diagnosis of sarcoma It is a medical axiom that the laboratory results must be correlated with the clinical findings in all

TABLE 6—*Histologic Types of Sarcoma*

Type	Cases
Fibrosarcoma	18
Angiosarcoma	3
Giant cell sarcoma	2
Neurosarcoma	2
Mixed cell sarcoma	1
Rhabdomyosarcoma	1
Myxosarcoma	1

branches of medicine Therefore, it is suggested that the diagnosis of sarcoma must be based not only on the histopathologic aspects but on the clinical findings and on the course of the neoplasm as well

In this series the diagnoses were made by 12 different pathologists While any given histopathologic section was examined by more than one pathologist in only a few instances, the fact that so many pathologists were involved ruled out the possibility that this series was influenced unduly by personal factors on the part of the examiner Furthermore, the mortality of 54 2 per cent speaks eloquently for the obvious fact that, whatever criteria are employed, most of these cases were instances of highly malignant sarcoma

The histologic types of the tumors are given in table 6 The cases of giant cell sarcoma may be included in the group of cases of fibrosarcoma, so that the latter diagnosis was made in 71 5 per cent of the total number of cases of sarcoma of the skin In other words, fibrosarcoma occurred three times as frequently in the skin as did all the other forms of sarcoma

7 Eller, J J, and Kest, L H Sarcoma Arising in an Organized Hematoma Resulting from a Single Trauma, Arch Dermat & Syph **43** 813 (May) 1941

easier to isolate than is T rubrum Additional evidence rests on correlation of types of lesions with etiologic agents In other words, if a patient presents a chronic hyperkeratotic lesion of the feet from which T rubrum has been isolated and a chronic hyperkeratotic lesion of the hand not yielding a culture, one may expect with a high degree of certainty that T rubrum is also the etiologic agent of the tinea manus

GENERALIZED DERMATOPHYTOSIS

Table 3 lists patients with verified dermatophytoses according to sites For 42 6 per cent (183 patients) there was evidence of one positive site, for 41 7 per cent (179 patients) of two positive sites, for 7 7 per cent (33 patients), of three positive sites, for 5 per cent (21 patients) of four positive sites, and in 3 per cent (13 patients), of five or more positive sites For the last-mentioned patients the infection was termed generalized 10 of the 13 patients were white, and 3 were

combined This is in contrast to the statements of Stewart and Copeland [8] and of Cutler, Buschke and Cantril,[9] who expressed the belief that soft tissue sarcoma is in most cases neurosarcoma In only 2 cases of this series was there evidence of associated von Recklinghausen's disease or of a tumor of a nerve trunk or of an unusual amount of nerve tissue in the sarcoma

Autopsies were performed in 9 cases Metastatic lesions were demonstrated in all 9 and, furthermore, the cell type of the metastases was identical with that found in the primary cutaneous tumor Death was due to cachexia or to terminal incidents, such as bronchopneumonia or nephritis The locations of the metastatic lesions are listed in table 7 This table indicates that metastases occurred most frequently in the lungs and the pleura, followed by the bones, the skin, the lymph nodes and the liver Autopsies revealed involvement of the deep lymph nodes more often than one would expect on clinical examination, suggesting that dissemination may occur through the lymphatic channels as well as through the blood stream

PROGNOSIS AND TREATMENT

Obviously, therapy is imperative in this highly malignant condition In 13 of 24 cases in which there was a follow-up period of nine months or more, the patient had already died of metastases at the time of the last observation This is a mortality rate of 54 2 per cent Undoubtedly, this percentage would increase with more prolonged observation Two patients died of other causes, and their deaths are not included as resulting from sarcoma In these 13 cases the average period from the onset of symptoms to death was 5 4 years In the 11 cases in which the patient is still living or has died from other causes the average survival is 5 3 years The total for the entire group was 5 35 years

8 Stewart, F W, and Copeland, M M Neurogenic Sarcoma, Am J Cancer **15** 1235 (July) 1931

9 Cutler, M , Buschke, F, and Cantril, S T Cancer Its Diagnosis and Treatment, Philadelphia W B Saunders Company, 1938, pp 659-666

Negroes Since white persons constituted two thirds of the total number studied, incidence by ratio was about the same for white persons as for Negroes

Cultures were isolated from 10 of the patients T rubrum was obtained from 8 white patients and T gypseum from 1 Negro and 1 white person Since T rubrum is more difficult to isolate than is T gypseum, one may assume that T rubrum is the cause of more than 80 per cent of the cases of generalized dermatophytosis

The most extensive case observed by us was that of R T, a 28 year old machinist, who stated that he had incurred the infection four years previously while he had been in the Navy The condition had remained chronic since that time and had gradually spread to cover three fourths of the body Both hands and feet showed chronic hyperkeratotic scaling of the palmer and plantar surfaces All toe nails and finger nails were infected Lesions of the chronic papulovesiculosquamous type extended from the area of the groin over the abdomen and buttocks and down the inner aspects of the thighs almost to the knees Similar lesions covered the forearms, the shoulders, the upper portion of the trunk and the neck and even extended onto the scalp T rubrum was isolated from several areas

SUMMARY

1 Of the various clinical types of dermatophytosis, tinea pedis ranked first in incidence, followed in order by tinea unguium, tinea cruris, tinea manus and generalized tinea

2 Multiple clinical types of dermatophytosis were noted in more than half the patients with verified infections

3 Chronic hyperkeratotic scaling is recognized as being the most frequent type of tinea manus, occurring in about 66 per cent of the verified cases

4 Infected toe nails occurred in 60 per cent of the cases of tinea pedis In only 18 of the 245 cases of tinea unguium was there no clinical or laboratory evidence of concurrent dermatophytosis

The longest life was twenty-two years, and the shortest in the fatal cases was one year after the appearance of the primary tumor

The earlier treatment is instituted, the better the prognosis If one employs a duration of six months as an arbitrary dividing line between early and delayed treatment, one finds that the mortality in the early-treated group was 30 per cent of the 10 patients receiving prompt attention On the other hand the mortality in 14 receiving treatment more than six months after the onset was 71 4 per cent While the number of cases studied may not be significant, these figures support the obvious thesis that the earlier adequate treatment is instituted, the better the prognosis It is to the credit of both the patients and the physicians that almost 35 per cent of the patients received treatment less than six months after the appearance of the tumor

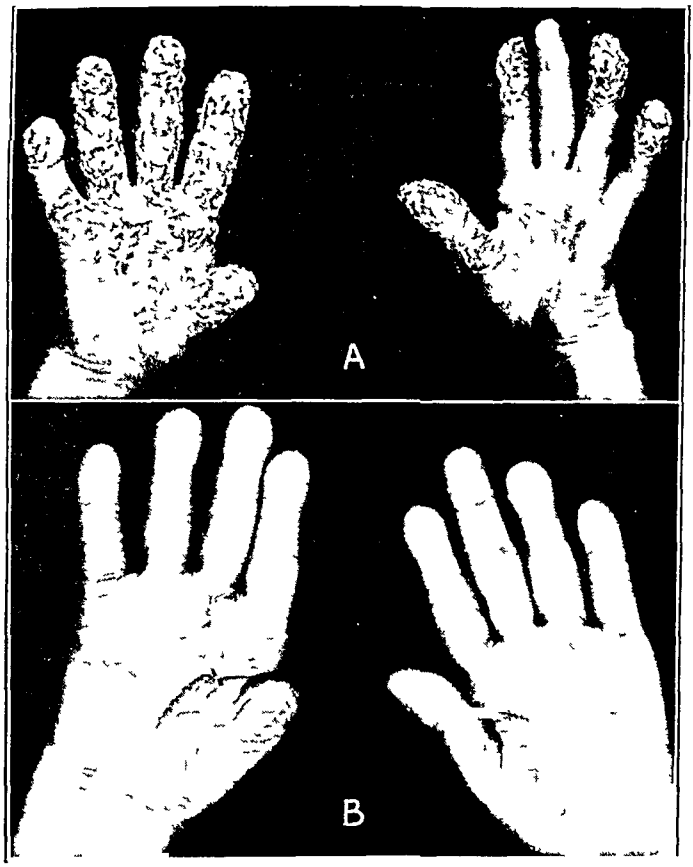
Three patients were untreated throughout the course of their sarcoma All died, the average period of survival being 4 3 years However, this

TABLE 8.—*Mortality with Each Type of Treatment*

Type of Treatment	Patients	Mortality
Excision	21	9 (42 7%)
Roentgen irradiation	7	6 (85 8%)
Amputation	3	2 (66 6%)
Curettage and electrodesiccation	2	0
Cyclotron irradiation	1	1 (100%)
Phosphorus ^{32} irradiation	1	1 (100%)
Radium irradiation	1	0
None	3	3 (100%)

comparatively favorable average is unduly influenced by the inclusion of a patient with a questionable diagnosis of low grade neurosarcoma This patient died ten years after the onset of his sarcoma, but death was due to an intercurrent tumor of the bladder diagnosed as carcinoma The average for the other 2 patients was 1 5 years, a figure which is probably closer to the true outlook for patients with untreated cutaneous sarcoma

It is difficult to compare different schemes of treatment because the prognosis depends on many factors, such as duration of the lesion prior to the onset of treatment, race, thoroughness of treatment and presence or absence of metastases Furthermore, a small series does not allow dogmatic statements Many patients received more than one form of treatment Table 8 shows the number of patients receiving each type of treatment and the number dying despite the approach utilized



It is important to note that more than 50 per cent of the patients treated by excision, with or without auxiliary measures, were still living at the time this study was conducted Furthermore, of 13 patients treated with excision alone, 7, or 53 8 per cent, survived Of 6 patients whom I personally treated by radical cautery excision, 4 are living and

Kaposi's Sarcoma Presented by DR JAMES H MITCHELL, DR RALPH SCULL and (by invitation) DR B YAFFE

Hidrosadenitis Suppurativa, Acne Vulgaris and Acne Conglobata, DR E E SENFAR and staff

Pustular Psoriasis, Healed After Tobacco Juice Soaks Presented by DR STEPHEN ROTHMAN and (by invitation) DR J H MCCREARY

S J, a housewife aged 57, was presented at the Chicago Dermatological Society meeting of Oct 16, 1946 The diagnoses suggested were pustular

Pustular psoriasis treated with tobacco juice soaks *A,* before treatment *B,* after treatment

psoriasis and acrodermatitis continua She had been hospitalized at the Albert Merritt Billings Hospital from June 12 to October 22 for observation and treatment

The patient was discharged from the hospital, unimproved, one week after the presentation, to be followed as an outpatient While at home, on her own initiative, she soaked her hands in hot tobacco juice six to eight times a day The juice was prepared by boiling tobacco in water for two minutes Each soaking lasted five to ten minutes Within one week considerable improvement

was seen in all the treated lesions, and almost complete cure of the hands and fingers was achieved in four weeks

Dr Edward Laden of our department could not demonstrate any antibiotic effect of the tobacco juice in vitro

Dermatitis Repens, Therapeutic Result Presented by DR F E SENEAR and staff

E L, aged 63, has been a patient on the dermatology service, Illinois Research and Education Hospital, since October 1946, with the diagnosis of dermatitis repens, affecting the first and second toes of the right foot On a previous admission intractable pain associated with a similar eruption on the left foot had necessitated amputation up to the middle of the thigh During the present period of hospitalization the following therapeutic agents were tried without noticeable improvement penicillin parenterally in large doses, sulfonamide drugs, staphylococcic toxoid, wet dressings of silver nitrate potassium permanganate and benzalkonium chloride, tyrothricin dressings, streptomycin ointment and repeated lumbar sympathetic blocks The most recent treatment has included a course of sulfapyridine by mouth and roentgen irradiation (twelve doses of 50 r, given twice weekly, terminating on May 12, 1947) No improvement was noted Immediately after application of compound tincture of benzoin ointment was started (May 28), oozing and crusting disappeared and epithelization began At present there is only a small area of dry healing granulations at the tip of the great toe

Pustular Psoriasis, Treated with Tobacco Juice Soaks Presented by DR STEPHEN ROTHMAN and (by invitation) DR J C MCCREARY

M K, a white housewife aged 53, was admitted to Albert Merritt Billings Hospital May 18, 1947, presenting widespread psoriasis of forty-eight years' duration Approximately fifteen years ago the palm of the right hand became pruritic and then pustular Some of the joints of the hand stiffened Later the tips of the fingers and toes became red, swollen and full of pustules Some nails were shed Repeated cultures failed to grow bacteria There have been remissions with improvement, of several years' duration, but never complete healing The present flare-up began four months prior to admission

In the past, various methods of therapy had been tried, including local applications of tyrothricin, penicillin, nitrofurazone, chloresium, ammoniated mercury, tar, roentgen irradiations, systemic administration of arsenic and vitamin B complex and a fat-free diet

Examination revealed well circumscribed, erythematous, partly crusted and partly hyperkeratotic patches on the scalp, trunk and upper and lower extremities The hands and toes showed subcorneal pustulation and crusting The right hand showed atrophy and contractures Both hands had stiffened interphalangeal joints Some finger nails and toe nails were missing, others were rudimentary

Wassermann and Kahn reactions of the blood were negative The urine was normal Examination of the blood revealed 12,800 leukocytes The differential count was normal Hemoglobin was 12 8 Gm Erythrocyte cells numbered 3,370,000 Blood lipids and cholesterol were normal The results of the sternal bone marrow examination was normal The basal metabolic rate was + 2 per cent A roentgenogram of the hands showed moderate arthritic changes involving the interphalangeal joints The electrocardiogram showed a tendency to left axis deviation

well without evidence of recurrence or metastases after an average survival period of 2 75 years One patient succumbed to metastases three years postoperatively There was no opportunity to make follow-up studies on the sixth patient [10]

Amputation does not offer a better prognosis than simple excision, provided, of course, that the latter is adequately performed In addition, excision avoids the permanent disability that follows amputation For instance, patient 11 presented a large nodular fibrosarcoma of the thigh of one year's duration The histologic section was classified as grade 2 The lesion was completely excised, and the patient is living and well eight years later Of perhaps even greater importance, she has been able to lead a normal life, having had two successful pregnancies since and being able to raise her children

Irradiation may cause regression of the tumor, but there is no evidence that it is curative Most authorities agree that these types of sarcoma are radioresistant Radiation therapy should not be used as a substitute for surgical removal nor can postoperative radiation act as a safety mechanism to compensate for inadequate excision

SUMMARY

A study of 28 patients with histologically proved sarcoma involving the skin is presented

The lesions start as small nodules, which become massive, necrotic, ulcerated, fungating tumors

Epithelioma is the most important of the lesions to be differentiated from sarcoma and the most difficult to differentiate

Precarcinomatous lesions may be presarcomatous, and patients with sarcoma may have associated carcinoma

To diagnose sarcoma on purely histologic grounds is difficult and may be fallacious The histologic observations should be correlated with the clinical findings and course

The earlier treatment is instituted, the better the prognosis The mortality was almost 250 per cent greater in the group receiving treatment after six months than in those being cared for less than six months from the onset of the tumor

Adequate excision is apparently the treatment of choice

10 These statistics must be modified, as metastastic lesions developed in 1 other patient while this paper was in press See footnote 4a

ment is most applicable to the matured "polar" lesions, it is least true with reference to the macular lesions It will be instructive, however, and of great practical value, for one to try to apply this observation to the simple, flat, usually hypopigmented macular lesions of the disease

Bacterioscopy The bacillary content of the tissue fluid at the border of the lesion is perhaps the most useful criterion If material obtained by Wade's "scraped incision" method [3] (which is still inaccurately but concisely called a "snip" in Hawaii) shows abundant bacilli, the lesion is probably lepromatous, if it shows few or none, the lesion is probably tuberculoid, if it shows moderate numbers, the nature of the lesion has not yet been determined, and the case, though not classifiable as either lepromatous or tuberculoid in type, may be said to be in the indeterminate group, at least so far as bacterioscopic evidence is concerned

The examination for bacilli may also be made on sections of tissue, preferably with the aid of Fite's formaldehyde modification [4] of the Ziehl-Neelsen stain More sensitive methods of searching for bacilli (as described by de Souza-Araujo [5]) are useful in diagnosis but not particularly helpful in differentiating the types

Neurologic Findings Concomitant and coextensive nerve damage is probably of almost equal importance in classifying the case as tuberculoid Demonstrable anesthesia which is identical in extent with the hypopigmentation is strong evidence that the lesion is not lepromatous but maculoanesthetic, i e, tuberculoid in immunologic type if not (yet) in histologic structure, for it is in this type that the neurolytic defensive reaction to the bacillus occurs In this connection, it is often forgotten even by experienced workers that anesthesia in leprosy is apt to occur in a dissociated pattern, e g, anesthesia to cold or heat or to both, with unimpaired sensitivity to light touch and to pinprick, is commonly found in early lesions In lesions manifesting no apparent anesthesia, the histamine test of Rodriguez and Plantilla [6] may be employed (in patients with light-colored skins) to detect lesser degrees of nerve dam-

BERYLLIUM GRANULOMAS OF THE SKIN

FRANK R DUTRA, M D
CINCINNATI

IN A RECENT paper, Grier, Nash and Freiman [1] have reviewed the literature relating to the effects which beryllium may have on the skin and subcutaneous tissues They recognized four distinct types of cutaneous reaction to beryllium Contact dermatitis occurs in persons working with soluble salts of beryllium, particularly beryllium fluoride or beryllium sulfate [2] Ulcers result when crystals of soluble beryllium salts become embedded in the tissues, these heal only after the crystals have been removed surgically or have been extruded spontaneously [2] In some patients suffering from chronic pulmonary berylliosis, granulomas of the skin occur, and these are similar to the granulomas which develop in the lungs [3] Grier and his co-workers have observed a fourth variety of cutaneous reaction to beryllium which they term "subcutaneous granuloma occurring in persons who cut themselves on fluorescent lamps"

Tissues received from 4 persons in whom subcutaneous granulomas developed after beryllium compounds had been traumatically introduced into the skin have been examined at the Kettering Laboratory We have also received tissues from an additional person in whom granulomatous inflammation of the subcutaneous tissues followed the introduction of metallic beryllium

CLINICAL DATA

The clinical data were essentially similar for all 5 patients In 4 the beryllium was embedded in the skin as the result of the accidental breaking of fluorescent lamp tubes and the puncturing of the skin by

This work was done under a contract with the Office of Naval Research

age, in darker skins the sweating tests described by Muir [7] and Degotte [8] (using intradermally administered pilocarpine or exercise) or by Myerson [9] and his associates (using methacholine), which seem to be just as sensitive may be used to better advantage [10] The important thing is the demonstration of nerve damage which is coextensive with the visible macule, this is highly characteristic of the maculoanesthetic—the "neural" or tuberculoid—form of leprosy

Clinical Aspects The remaining clinical features by which one may judge the hypothetic macule constitute much less useful criteria of its type The classic lepromatous macule tends to be multiple, and the tuberculoid, solitary, but many exceptions occur The lepromatous macule generally has a poorly defined border, often with fine pseudopod-like irregularities, the tuberculoid macule is usually sharply outlined By the same token, lepromatous macules tend to confluence and tuberculoid ones to discreteness Lepromatous macules are likely to occur on the trunk, a macule on the face or extremities is more commonly of the tuberculoid variety The lepromatous macule usually persists for many months or alternatively progresses into the clinical lesion known as a leproma, the anesthetic macule is likely to show evidence of regression within six months to a year None of these findings, however, is conclusive, and if the bacterioscopic and neurologic criteria are inconsistent one must resort to biopsy Indeed, biopsy should be done anyway, as a routine precaution

Histologic Changes Histologic changes in such early and minimally advanced lesions as the macules being discussed are pretty likely to be banal so far as the general pathologist's interpretation of them is concerned Ermakova, of Moscow,[11] found them so in a considerable series of anesthetic flat "macules" Wade,[12] on the other hand, found changes which he regarded as "nearly always in some degree tubercu-

fragments of glass The fluorescent powder which lines tubes of this type is comprised of a calcined mixture of zinc oxide, manganese oxide, beryllium oxide and silica In these 4 patients the lacerations healed with production of excess fibrous tissue Two of the lesions, when first seen by physicians, were believed to be simple keloids All four lesions, on one or more occasions after initial healing, opened to discharge thick,

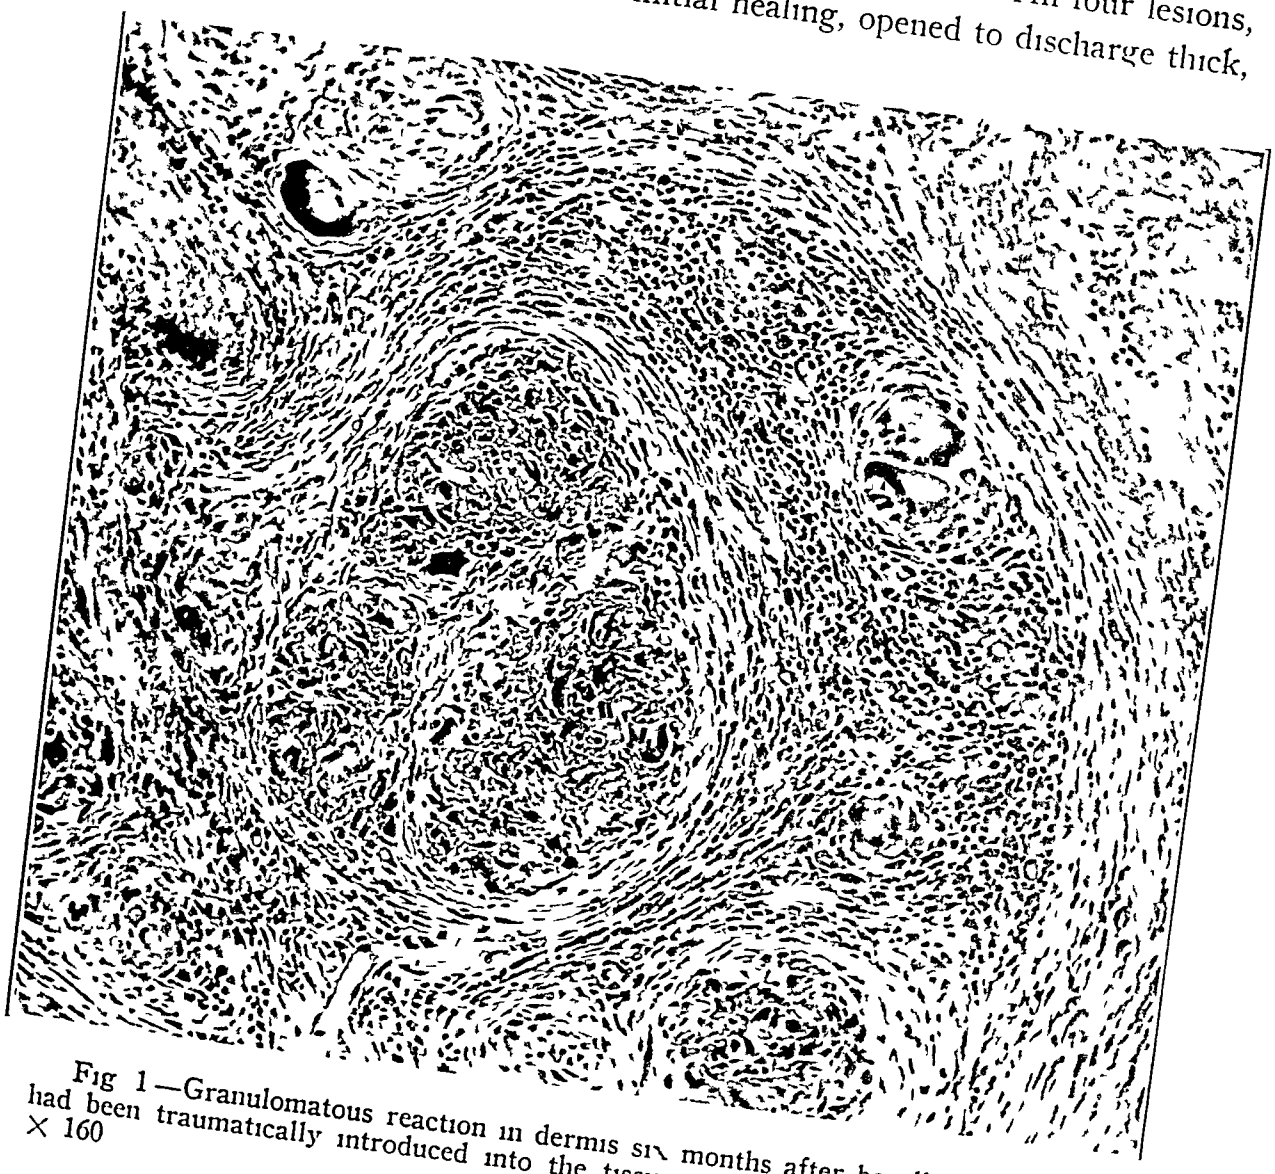

Fig 1—Granulomatous reaction in dermis six months after beryllium phosphor had been traumatically introduced into the tissues, hematoxylin and eosin stain, × 160

grayish white necrotic material The period from injury to excision varied from four months to nine years

A fifth patient discussed here was a young woman who worked at cutting metallic beryllium with a machine and had accidentally lacerated her finger during her work A granuloma developed, and this failed to heal over a period of four years, so that finally a complete excision of the lesion was made

loid" in a larger series of similar lesions He often found it necessary to employ serial sections, however Ota and Sato,[13] in Japan, came independently to exactly the same conclusion in the same year

What is meant by "in some degree tuberculoid"? Not fully developed, noncaseating, epithelioid cell tubercles, to be sure In general, the designation refers to an infiltrate of rather sharply focal arrangement, composed of both lymphocytes and epithelioid cells, which may or may not be arranged in the pattern of definite tubercles Diffuseness or vague margination of the infiltrate and scarcity of lymphocytes are both suggestive of the lepromatous form of the disease

THE INDETERMINATE GROUP

If bacterioscopic, neurologic, clinical and histologic changes are inconclusive or inconsistent, the problem is a more difficult one, it may indeed be incapable of solution for the time being The South American dermatologists, perhaps impatient at the postponement of an exact diagnosis, have urged the establishment of a third "type" or "form" of leprosy to include all such cases they suggested calling them *incaracterístico* (uncharacteristic) At the Fifth International Congress for Leprosy, in April 1948, the words "indeterminate" and "group" were agreed on the former because it permitted the use of the same initial letter, *I*, in Portuguese, Spanish, French and English, and the latter to indicate that this term designated, not a third type of leprosy, but only a group of cases, defined largely by their lack of definitive characteristics It has been shown that such cases may remain in this neutral status for a variable period, at the end of which they will heal, become lepromatous or become tuberculoid

In addition to the differentiating criteria which have been discussed, there is one more point, regarded by some workers as the most informative and important of all, which presents so many ramifications that I shall discuss it under a separate heading

LEPROMIN (FERNÁNDEZ AND MITSUDA) REACTIONS

Kensuke Mitsuda reported in 1916[14] that the intracutaneous injection of a small amount of a phenolized, boiled suspension of finely divided lepromatous granulation tissue (a mixture of dead Mycobacterium leprae and human tissue) would produce a slowly developing often ulcerated papule in the great majority of patients with the "maculoanesthetic" (i e, tuberculoid) form of leprosy, as well as in many

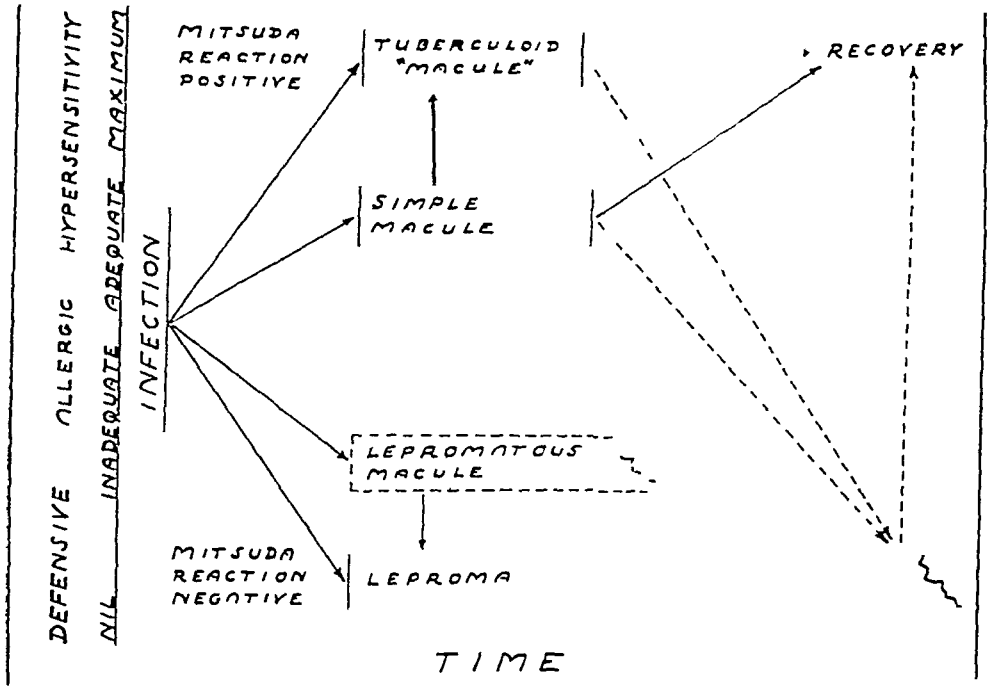
HISTOPATHOLOGIC OBSERVATIONS



The tissues which were excised four months after the phosphor-containing beryllium oxide had been introduced into them were found to be the site of a granulomatous reaction in which there were areas of

Fig 2.—Focal necrosis and granulomatous inflammation of dermis four years after metallic beryllium had been introduced into the tissues, hematoxylin and eosin stain, × 160

necrosis The necrotic areas involved the dermis and subcutaneous tissues, and they were not unlike the areas of caseation in tuberculosis, they were, however, much more extensive than those in the rare cases

presumably uninfected persons, it regularly produced little or no reaction in the great majority of patients with the "tubercular" (the nodular, or lepromatous) form He extended and amplified his observations in a series of reports, which received little attention in this country until the publication of a paper by his student, Hayashi, in 1933 [15] His observations have since been widely confirmed Numerous studies have been made in an effort to improve and standardize the test by purification and fractionation of the test material These have not been especially rewarding, however, since the crude preparation seems as potent as and no less specific than, its various fractions [16]

Diagrammatic oversimplification of the major cutaneous lesions of leprosy as functions of (1) "defensive allergic hypersensitivity" to the bacillus and (2) time Note that this hypersensitivity may already exist at the time of infection, that it may either increase or decrease after infection occurs, that it may be demonstrated by a positive Mitsuda reaction, that it results, in general, in self limited lesions known as "macules," that its failure to develop results in essentially persistent or progressive lesions and that it rarely, if ever, develops late in the course of the disease Note, too, that exceptionally this hypersensitivity may be lost, resulting in transition of the disease to the lepromatous form and that, also exceptionally, recovery will occur in a lepromatous case, without, however (or sometimes with?), transition through a tuberculoid phase

The term "defensive allergic hypersensitivity" is to be taken loosely, not literally And the prognosis as indicated does not take into account the effect of treatment with sulfone derivatives

15 Hayashi [14b]

16 Davey, T F Some Observations on the Role of Allergy in Leprosy, Leprosy Rev **17** 42 (July), 75 (Oct) 1946

of Boeck's sarcoid in which caseous necrosis does occur [4] There was amorphous, slightly eosinophilic, granular material, and at one point a small, highly refractile mass of foreign material was present Around the necrotic center there were large mononuclear cells, some of which were polyhedral while others were spindle-shaped These cells had large reticular nuclei, so that they resembled epithelioid cells The necrotic areas were surrounded by a zone of partially degenerated, elongated cells resembling fibroblasts, around which there was cellular

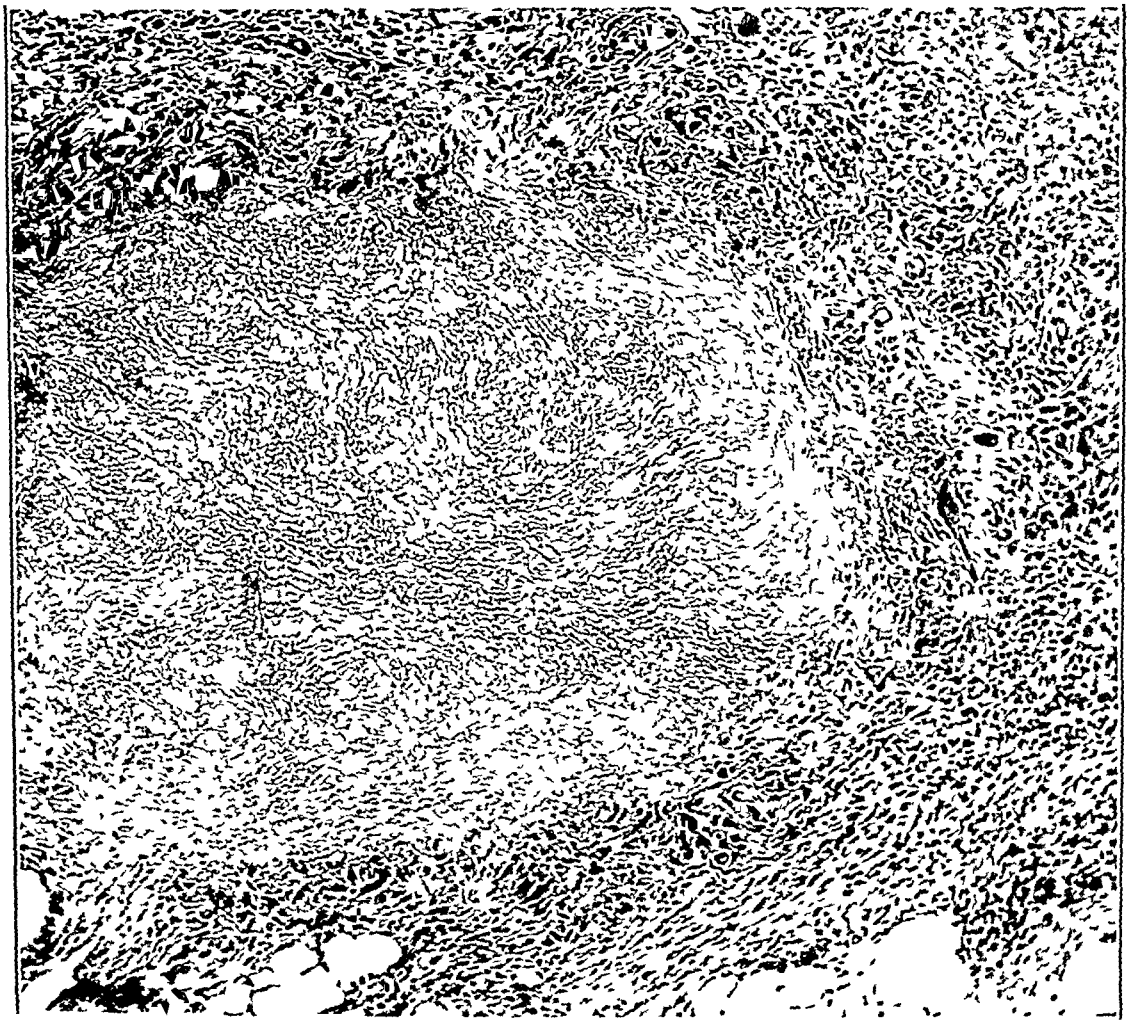


Fig 3—Area of necrosis of dermis four months after introduction of beryllium phosphor, hematoxylin and eosin stain, × 115

collagenous tissue infiltrated with large numbers of lymphocytes The remainder of the tissue was divided by relatively dense strands of connective tissue into nodules of varying sizes The nodules were comprised in most instances of relatively loosely arranged connective tissue, in which there were elongated and polygonal cells with large reticular nuclei, surrounded by elongated fibroblasts and a few lymphocytes The

4 Goldman, L Personal communication to the author

Fernandez,[17] in 1940, reported that the often observed tuberculin type of reaction to lepromin, reaching peak severity in forty-eight hours instead of the two to five weeks required for the Mitsuda reaction, could be correlated with the clinical form of the leprosy virtually as closely as could the latter Dharmendra and Lowe,[18] in 1943, showed that this response could be elicited regularly by injection of the purified protein, presumably the nucleoprotein, of the bacilli The injection of the crude antigen, on the other hand, generally produced relatively little effect until the bacilli had had time to break down and liberate this antigenic material It is highly probable, at all events, on the basis of this evidence and the analogy with some (though by no means all) forms of tuberculosis, that a positive lepromin test indicates acquired allergic hypersensitivity to the antigens of the leprosy bacillus, though this may have been acquired without infection by, or even contact with, the organism in question I know of no student of leprosy who believes that a strongly positive Mitsuda reaction can occur in a patient with low resistance to leprosy, or a negative or even a feeble reaction in one with high resistance The allergic response and the defensive one seem, in leprosy, inseparable

Hayashi[14b] and others showed that the Mitsuda reaction may be more pronounced in tuberculoid "macules" than in normal skin This observation was confirmed most recently by Davey[16] The reaction is apt to be stronger in elevated tuberculoid "macules" than in flat ones and is usually strongest in their borders A positive reaction is also occasionally found, according to Davey, in lepromatous macules, even when the normal skin outside the macule gives a negative reaction Dharmendra,[19] in a recent extensive review of the literature on the lepromin test, stated that he had not been able to confirm this observation, and my experience in Hawaii has been similar

SIMPLE (FLAT) MACULES VERSUS TUBERCULOID (ELEVATED) "MACULES"

I have discussed in some detail the features of the two types of flat macules, the lepromatous and the anesthetic, or simple The elevated or tuberculoid, "macules" present no such highly refined problem in differentiation, for in them the allergic hypersensitivity to Myco leprae is strongly and usually securely established The histologic changes which are almost invariably of the tuberculoid pattern, with

entire nodules were surrounded by relatively dense connective tissue in circumferential arrangement In the centers of some of the nodules and in the peripheral portions of others were multinucleated giant cells of the Langhans type, some of which were as small as 20 microns in diameter, while others were as much as 200 microns in diameter Some of these giant cells had within their cytoplasm small masses of highly refractile substance, but in none were there inclusion bodies of the type described by Schaumann [5] or of the type described by Wolbach [6]

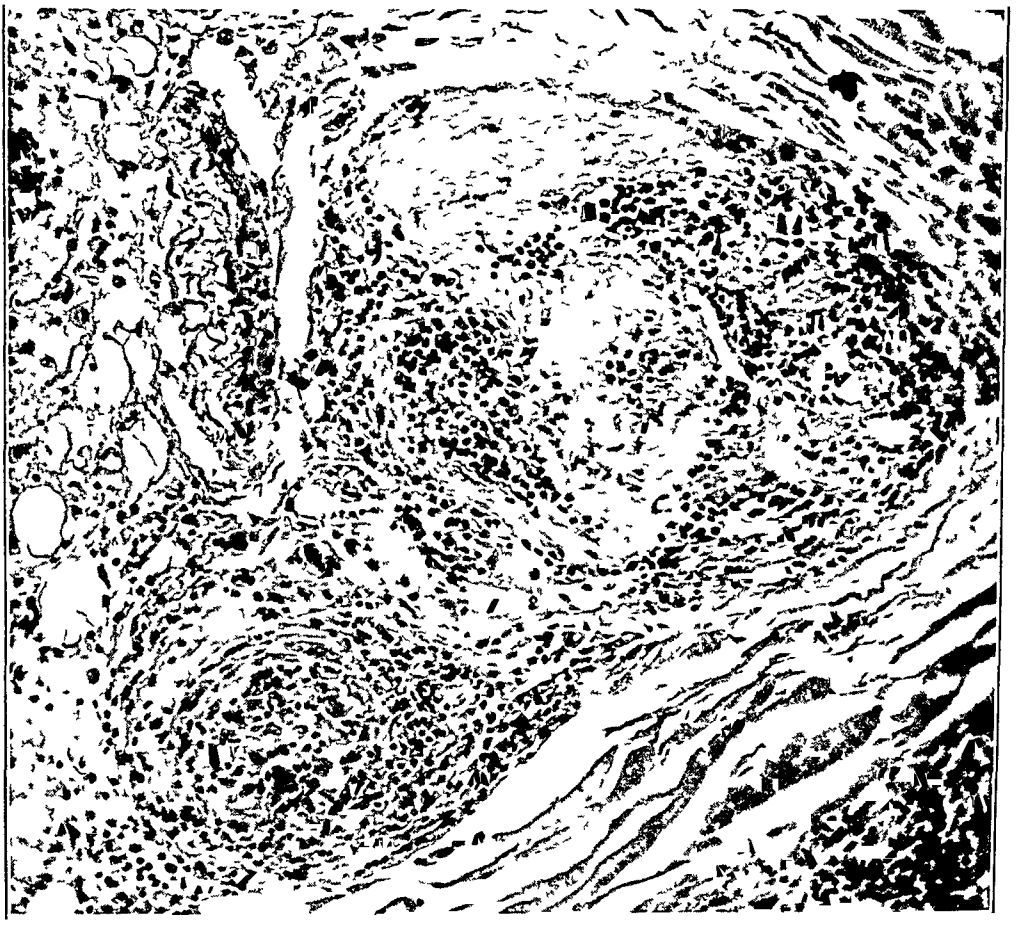

Fig 4—Marked fibrosis of individual nodules in granuloma nine years after beryllium phosphor was introduced into dermis, hematoxylin and eosin stain, × 160

The lesions occupied the dermis and the uppermost portion of the subcutaneous tissues The epidermis was intact, and there were

well defined, noncaseating, epithelioid cell tubercles and no or comparatively few bacilli; bear out this statement, in accordance with the observations of Jadassohn and Lewandowsky It seems probable that in these lesions there is elaboration of abundant antibody by the histiocytes in the skin, and a resultant antigen-antibody reaction which effectively eliminates the bacilli Why this inflammatory reaction is rarely accompanied with necrosis when it occurs in the skin, and is usually accompanied with it when it occurs in the nerves, is not clear, but this finding has often been reported,[20] and my observations in Hawaii have regularly confirmed it Of course this necrosis of nerve tissue is the reason for the regular occurrence of anesthesia or anhidrosis in even the earliest "macules," and it has led to the confusion begun by Danielssen and Boeck [21] (and checked only for a time by Hansen and Looft [2]), resulting from the designation "anesthetic" or "nerve" or "neural" for cases of this form of the disease and also for lepromatous cases with more nerve damage than cutaneous damage

It may be significant that there is not necessarily any difference between this tuberculoid response, produced by presumably living Myco leprae, and a positive Mitsuda reaction, produced by dead ones, for, indeed, as Davey [16] pointed out, if the former happens to be vigorous and intense enough, or to be accompanied by sufficiently pronounced fixation of the bacilli in the tissues, it may run the same swift and benign course as the Mitsuda test, with final complete resolution in a few weeks or months Ordinarily, however, the multiplication of bacilli, ahead of (or in) the advancing border of the lesion, is able to keep slightly ahead of the development of the defensive tissue reaction, so that gradual spread occurs, and only after some months, or even longer, does either the "anchoring" of the bacilli or the more effective production of antibodies permit all the organisms to be destroyed, so that the lesion heals Healing often occurs in the central zone and spreads peripherally, so that annular lesions from a few millimeters to several decimeters in diameter are formed, and "cockade" patterns, produced by successive fluctuations in the vigor of the antigen-antibody reaction, are not unusual Such patterns are not infrequently observed in patients whose disease is undergoing transition from the tuberculoid to the lepromatous type

The effectiveness and persistence of this combined defensiveness and hypersensitivity may vary widely Transitory relapses after complete or partial healing of the lesions are not rare Even gradual, persistent

moderate acanthosis, hyperkeratosis and parakeratosis The peripheral portions of the lesions were infiltrated by numerous lymphocytes, but within the lesion itself such cells were relatively few

The lesions from 3 other patients who had had phosphors embedded in their skin for periods of from one to four years before excision were similar to the one described The lesion from the woman who had had metallic beryllium embedded in her skin for a period of four years was also similar to the one described

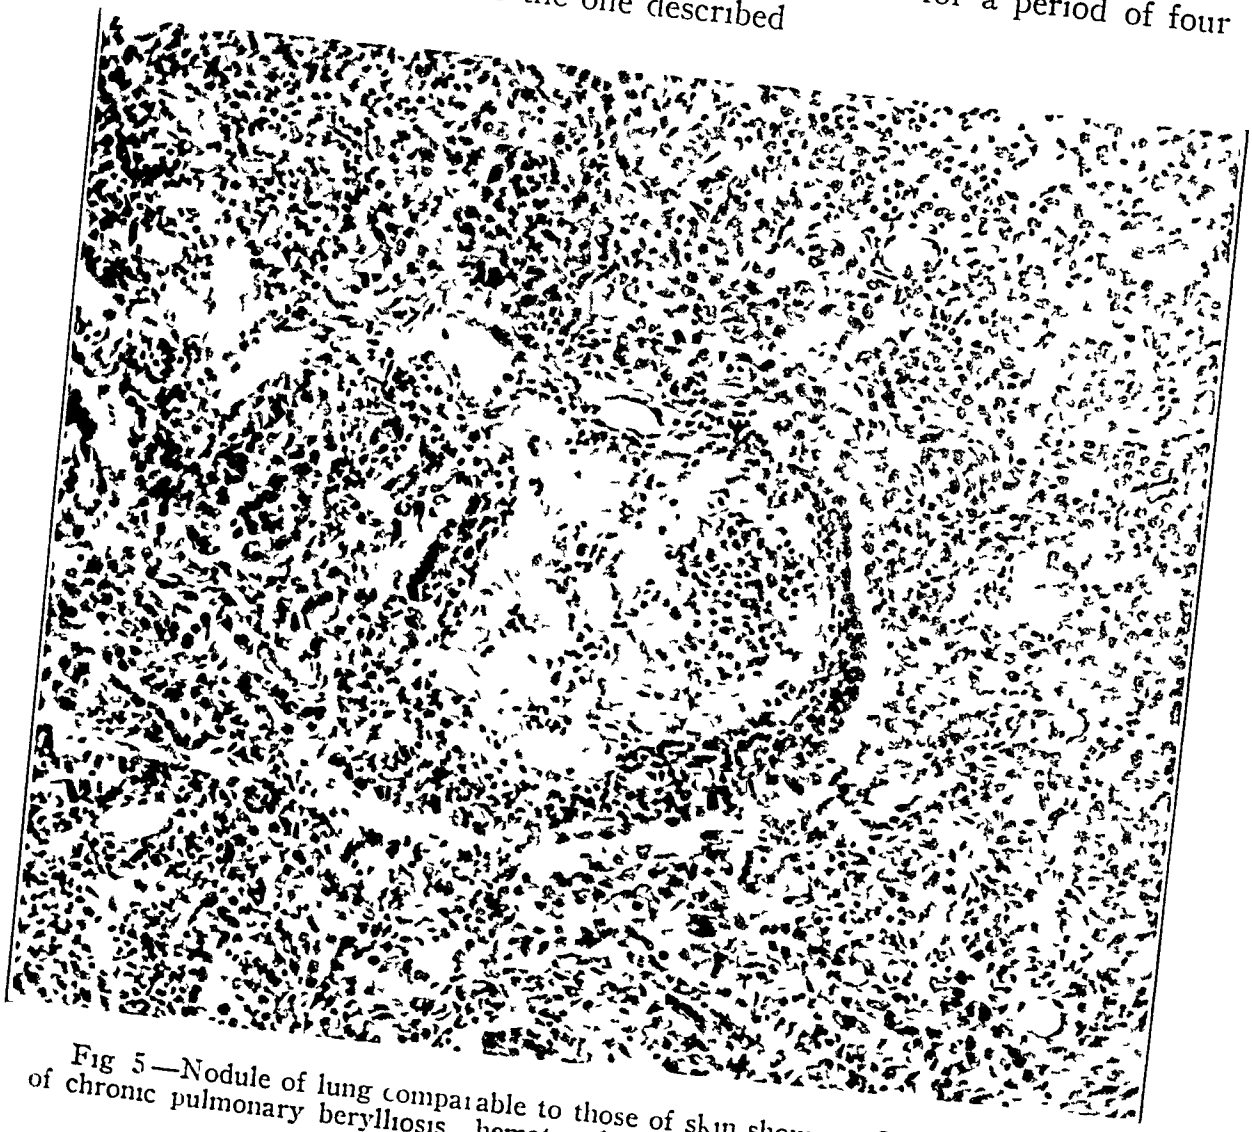

Fig 5—Nodule of lung comparable to those of skin shown in figure 4, in a case of chronic pulmonary berylliosis, hematoxylin and eosin stain, × 160

The lesion in the skin of the man who had had beryllium phosphor embedded at that site nine years before it was excised differed somewhat in degree of development from those the duration of which had been four years or less In the nine year lesion the general picture was one of dense, relatively acellular collagen in which were numerous small nodules comprised of large cells The latter were for the most part compactly arranged, with poorly defined pale cytoplasm and large vesicular nuclei Occasional small multinucleated cells which resembled

loss of hypersensitivity, with resultant reversal of the lepromin reaction to negative and transformation of the lesions from tuberculoid to lepromatous, may occur, though it is so infrequent that some workers have never observed it and some, indeed, doubt that it occurs I have seen it occur twice, both times in patients with large and numerous "major tuberculoid" lesions The first alarming sign was the tendency of both patients to have frequent exacerbations of the cutaneous lesions (tuberculoid reactions) Wade [22] described this process in detail in a few cases The reverse of this phenomenon of transition (i e, a change from the lepromatous to the tuberculoid type) seems to be much rarer, presumably because the patient will usually develop hypersensitivity and resistance to the bacillus early in the course of his infection if he is capable of developing them at all The only definite evidence that transformation in this direction can occur, in fact, was presented recently by Lauro de Souza Lima [23]

TUBERCULOID "MACULES" VERSUS LEPROMAS

In considering tuberculoid "macules" in contrast with lepromas, one is dealing with the easily distinguished "polar" lesions of the disease the two extremes, one representing victory for the patient's defensive processes and the other representing victory for Myco leprae All that was said about the differentiation of the lepromatous macule from the simple or anesthetic macule may be applied here The tuberculoid "macule" (whether macule or plaque) is regularly anesthetic, the leproma is anesthetic only if (as occasionally happens) it occurs in an anesthetic area of skin The tuberculoid "macule" typically contains few or no bacilli, even in reactions, it rarely contains the abundance of bacilli found regularly in a leproma The tuberculoid "macule" characteristically shows noncaseating, epithelioid cell tubercles, with abundant lymphocytes, histologically, the leproma has the architecture and composition of a fatty foreign body granuloma, or xanthoma, in which the lipid material is presumably furnished by the masses of Myco leprae, and in which lymphocytes are few

Clinical features, as with the flat macules, are less trustworthy, however, like flat tuberculoid macules, tuberculoid plaques are somewhat more likely to be solitary, or few, and asymmetric, and lepromas, generalized and symmetrically distributed Lepromas tend to develop earliest and most conspicuously on acral parts ears, forehead chin, buttocks, elbows and fingers Tuberculoid lesions show little or no

22 Wade, H W, and Rodriguez, J N Borderline Tuberculoid Leprosy, Internat J Leprosy 8:307 (July-Sept) 1940

23 Lima, L de S, and de Souza Campos, N Immuno-Biologic Anomalies in Leprosy Internat J Leprosy 16:9 (Jan-March) 1948

Langhans' cells were present There was a large number of lymphocytes scattered throughout these nodules, interspersed between the large cells Many of the nodules had dense collections of numerous lymphocytes in their peripheral portions, and practically all of the nodules were surrounded by collagen which contained only a few small connective tissue cells In some places this collagen was hyalinized

In 3 of the 5 cases sufficient amounts of tissue were available to permit chemical analysis The tissues were analyzed for beryllium by the method of Cholak and Hubbard,[7] and small quantities of beryllium were recovered in 2 cases but could not be recovered in the third

COMMENT

The evidence which supports the opinion that beryllium is capable of producing fibrosis has been presented in a paper[8] in which 13 cases of chronic pulmonary berylliosis with fibrosis and granulomas are described Among 7 cases of acute pneumonitis due to the inhalation of fumes or dusts containing beryllium, there were organization of exudate and early fibrosis in 5, and the lesion progressed to the first stage of the formation of fibrous nodules in 3 Further support of the opinion that beryllium is capable of inducing fibrosis has come from experimental work in which the reactions induced by metals embedded in bone were studied[9] It was found that a certain alloy containing nickel, cobalt, chromium and molybdenum was innocuous, but that when beryllium was added to the alloy in the concentration of 1 6 per cent, granulation tissue formed at the site of the alloy and lymphocytes infiltrated the tissues

The diagnosis of beryllium granuloma of the skin can probably be made clinically when there is a history of beryllium or one of its compounds having been embedded in the skin Lacerations produced by glass from fluorescent lamp tubes are likely to lead to the development of beryllium granulomas, since beryllium oxide is a constituent of the phosphorescent powders used in making these tubes Tissues into which the material has been introduced will, over some months, show formation of excessive scar tissue, which occasionally opens and drains Biopsy of such tissues reveals lesions which could be confused with caseous tuberculosis or Boeck's sarcoid Differentiation rests on the presence of beryllium demonstrated by analytic methods, and on the absence of

real predilection for these parts A sharply defined and elevated border or a clearing center is much more likely to be manifested in a tuberculoid lesion than in a leproma, though the sharply clear center, with a less clearly defined outer margin, suggests the leproma rather than the tuberculoid lesion Norman Sloan [24] pointed out that lepromas have a strong tendency to respect facial and other natural grooves and creases, such as the nasolabial fold and the angle between the root of the nose and the inner corners of the eyes, a tuberculoid plaque will often invade and involve such areas Involvement of the mucous membrane (of the eye, mouth, nose, throat and larynx) and testicular involvement occur only in lepromatous cases Nerve involvement occurs regularly in both lepromatous and tuberculoid cases, but nerve damage is produced only slowly by the gentle, passive, bacteriophagic lepromatous response, whereas it is produced early and rapidly by the vigorous, defensive, bacteriolytic tuberculoid response

SUMMARY AND CONCLUSIONS

The flat macules and elevated "macules" of leprosy apparently represent circumscribed cutaneous areas of acquired allergic hypersensitivity to the nucleoprotein of Myco leprae

If this hypersensitivity is lacking or inadequate to destroy the organisms, the macule is called a lepromatous macule, and it can usually be identified as such by the abundance of bacilli in it and its failure to manifest anesthesia or other evidence of nerve damage

If this hypersensitivity is adequate to destroy the organisms, the lesion is then often spoken of simply as a "macule" (or, better, a tuberculoid plaque), and it can usually be recognized by its relative lack of bacilli and the regular occurrence of evidence of nerve damage throughout its visible extent If such lesions are flat they are sometimes called "simple macules" or "anesthetic macules", if they are elevated they are usually called "tuberculoid macules" Both terms were included under Unna's word "leprides"

The development of an adequate degree of resistance and allergic hypersensitivity to Myco leprae results in the establishment of a relatively favorable form of leprosy which has been known as the "anesthetic" (Danielssen, 1847), "maculoanesthetic" (Hansen, 1895), "neural" and, more recently, "tuberculoid" form

The failure of development of such a state following infection with Myco leprae results in the establishment of an unfavorable form of leprosy known as the "tubercular" (Danielssen), "nodular" (Hansen), "cutaneous" and, more recently, "lepromatous" form

24 Sloan N R Personal communication to the author

tubercle bacilli The beryllium lesion can be differentiated from Boeck's sarcoid by the presence of caseous areas and by the large number of lymphocytes scattered throughout, particularly in the periphery of the lesion It is probable that tertiary syphilis might simulate the cutaneous beryllium granuloma, and the differentiation would depend on the demonstration of treponemas and the failure to demonstrate beryllium Nodular leprosy and certain cutaneous fungous diseases would present only minor difficulties of differentiation

The treatment of cutaneous and subcutaneous granulomas which follow the introduction of beryllium or its compounds has been successful in the 5 cases reported here only when the tissues containing the foreign material have been completely excised Before excision, in each case, the lesion was marked by excessive formation of scar tissue and repeated episodes of discharge of the wound, followed by temporary healing

SUMMARY

Five cases of chronic granulomatous inflammation of the skin and subcutaneous tissues following the introduction of beryllium or beryllium compounds are presented

The histologic relationship of the granulomas of the skin and similar granulomas which occur in the lungs of persons who have inhaled beryllium-containing dusts in industry is described

Cure followed excision of the lesions in all cases

Such hypersensitivity, once developed, usually results in eventual spontaneous cure of the infection, it may, however, be lost, with resultant transition of the case from the tuberculoid to the lepromatous category

The lepromin test appears to be a fairly trustworthy method of measuring this hypersensitivity, both in normal skin and in macules

The Clinic, South Hotel Street at Thomas Square (13)

ABSTRACT OF DISCUSSION

DR BRAULIO SÁENZ, Habana, Cuba The last time our Association met on the Pacific coast was in 1938, at Del Monte, Calif At that meeting I presented a paper on tuberculoid leprosy (ARCH DERMAT & SYPH **39** 456 [March] 1939), the first on this subject in North America The paper was written prior to the holding in Cairo of the Fourth International Congress for Leprosy and was read shortly thereafter It was at that congress that the South American classification of leprosy was rejected and the Cairo classification adopted

My paper, being a pioneer one and based on a limited number of observations, was no doubt incomplete and not devoid of some minor erroneous interpretations Ten years later, on April 10, 1948, the Fifth International Congress for Leprosy took place in Habana, and the South American classification (now known as the classification of Habana) was adopted Dr Arnold has very aptly outlined his paper on this classification, which, for the time being, is the only one tenable, because it is based on the following points (1) the morphology, or clinical aspect of the lesions, (2) immunologic reactions, (3) bacteriologic criteria and (4) a more or less definite histopathologic picture

The presenter stresses the importance of these fundamental bases and discusses the position of the indeterminate groups, previously called uncharacteristic This, as he indicates, may be the possible weak point of this classification, but one must remember that, not only in leprosy, but also in many other dermatologic processes, only the evolution determines the real position of certain cases and that borderline cases are often observed In addition, this group, in the majority of cases, presents a negative reaction to the Mitsuda test, which is a possible indication of future transition to the lepromatous form

The publications of F Fischl (*Dermat Ztschr* **55** 274 [March] 1929), and of Jadassohn (ARCH DERMAT & SYPH **21** 355 [March] 1930) and the communications of I Darier, Civatte, P Woringer and H Gougerot to the International Dermatological Congress at Budapest in 1935 (Deliberationes Dermatologorum Internationalis, IX-1, Budapest, September 1935, Leipzig, Johann Ambrosius Barth, 1936) made important contributions explaining the role of the biologic reactions of immunity on the morphologic aspects of the cutaneous lesions, nevertheless, some points remain unanswered For example, some have denied the possibility of the transformation of the tuberculoid lesions to the lepromatous form, despite such denial, this transformation is an established fact Dr Arnold has observed 3 such cases, and I have seen 4 Some three months ago, I requested Dr Nelson Souza Campos who has had considerable experience in the treatment of patients in the Sanatorio Padre Bento São Paulo, Brazil, for his opinion on the subject He replied to the effect that he had observed 64 cases of tuberculoid leprosy of the reactional type which had undergone transformation to the lepromatous type All cases were observed in patients in leprosy asylums The possible explanation is that these patients had been superinfected from other lepromatous patients This explanation did not apply to my patients who were all encountered in my private

"MACULES" OF LEPROSY

HARRY L ARNOLD Jr, M D
HONOLULU, HAWAII

THE WORD "macule" has long been used by students of leprosy in two quite different and yet overlapping senses Exceptionally, it has been used in the orthodox sense of a circumscribed, flat discoloration of the skin (usually hypopigmentation, and less often erythema), and in this use it is, oddly enough, usually qualified as either "lepromatous" or "simple" (or "anesthetic") or, more recently, "uncharacteristic" or "indeterminate"

The term has been much more commonly used, however, in a sense at once looser and more restricted, and certainly not at all orthodox Without any qualifying adjective, the word "macule"[1] has been used to designate any circumscribed, discolored (hypopigmented erythematous or both) cutaneous lesion, flat or elevated, in which (1) evidence of nerve damage (usually anesthesia) can be demonstrated and (2) bacilli are rare or absent When such a lesion is flat, it is often spoken of as a simple or an anesthetic macule, when it is elevated (and sometimes even when it is not), it is often called a tuberculoid 'macule"

There is, then, a morphologic macule, which is (by definition) flat but may occur in either the lepromatous or the tuberculoid form of leprosy, and an immunologic "macule," which may be either a (flat) macule or an elevated plaque but occurs only in the tuberculoid form of leprosy The lepromatous macule, for reasons which will be discussed presently, occurs relatively infrequently This fact has led to the practice of using the unqualified word "macule" almost entirely as a designation for the circumscribed, anesthetic, paucibacillary macules and plaques—the leprides of Unna which characterize the maculoanesthetic or "neural" or, as the Fifth International Congress for Leprosy named it, the tuberculoid form of the disease

LEPROMATOUS MACULES VERSUS "MACULES"

As Hansen observed over fifty years ago,[2] the "two forms [of leprosy] are clinically pretty sharply distinguishable" This state-

From the Clinic
Read at the Sixty-Eighth Annual Meeting of the American Dermatological Association, Inc, San Diego, Calif, April 26, 1948

1 Quotation marks will be used throughout this article wherever the word is being used in this sense rather than in the literal dermatologic sense

2 Hansen, G A, and Looft, C Leprosy in Its Clinical and Pathological Aspects translated by N Walker, Bristol, J Wright & Co, 1895

practice Therefore, I should like to ask Dr Arnold whether his cases were encountered in an asylum or in private practice Through the action of the sulfone drugs, the reverse of this transformation was reported to the Fifth International Congress for Leprosy by Lauro de Souza Lima (*Internat J Leprosy* **16** 127 [April-June] 1948) Lepromatous leprosy was transformed into the tuberculoid type The histopathologic changes from one form to the other were checked at different dates, the tissular changes appearing first as the expression of an acquired immunity, later the reaction to the Mitsuda test became positive, and as a final stage came the curability of some of the cases Before closing I wish to congratulate Dr Arnold heartily on his timely paper, it is simple and concise, and it gives complete descriptions of the polar and of the indeterminate forms of leprosy, as well as valuable information to the dermatologist respecting correct diagnosis, prognosis and epidemiology of the disease

I also wish to express my satisfaction for the opportunity I have been given to open the discussion on this excellent contribution, in addition, it gives me pleasure to inform Dr Arnold that I have been requested to advise him that he has been proposed as a correspondent member of Sociedad Cubana de Dermatologia y Sifilografia, and of Academia Espanola de Dermatologia y Sifilografia, as a reward for his qualifications as a dermatoleprologist

DR LOUIS WINER, Los Angeles I wish to compliment Dr Arnold on his excellent paper My associates and I have had such cases on two occasions in Los Angeles These cases histologically were definitely tuberculoid in structure On use of the Ziehl-Neelsen stain, numerous acid-fast bacilli were observed The reaction to the lepromin test was negative Because of these observations we were unable to classify the patients However, the indeterminate group provides a classification modification, so that now these patients can be classified I think that the histologic characteristics of tuberculoid formation are indicative that a better prognosis can be expected than if these characteristics were not present

DR HAMILTON MONTGOMERY, Rochester, Minn I should like to ask Dr Arnold and Dr Saenz about recent reports in the literature regarding the reaction to lepromin in patients with sarcoid and tuberculosis It would appear that in sarcoidosis there is a negative reaction, whereas in active pulmonary tuberculosis the reaction may be positive If such observations are substantiated, the lepromin test might be of diagnostic value in northern climates where leprosy is not endemic in distinguishing between an annular sarcoid and a tuberculoid leprosy Both show an epithelioid tuberculoid reaction histologically, so that in older literature in Scandinavian countries the question was raised as to whether the patient had sarcoid or tuberculoid leprosy Tuberculoid leprosy, I understand, gives a positive lepromin or Mitsuda reaction

DR FRED D WEIDMAN, Philadelphia I should like to ask Dr Arnold whether he is able to get a supply of *Nachtblau,* which Dr Pardo-Castello told us about and which is superior to the ordinary Ziehl-Neelsen technic for staining the bacilli

I have tried to secure a supply, without success Does he think that the Fite technic is also superior?

DR HARRY L ARNOLD JR, Honolulu, Hawaii I am obliged to all the discussers Dr Saenz asked whether the transitional cases were private or asylum cases they were all asylum cases, 1 in Mexico and 2 in Hawaii, and all showed typically tuberculoid annules with the "cockade" pattern, with numerous bacilli and (in those seen in Hawaii, at least) a negative reaction to the lepromin test Dr Winer's cases with tuberculoid lesions with numerous bacilli may be examples of

Biopsy of left knee joint capsule showed no abnormalities Biopsy of the skin showed changes typical of pustular psoriasis

While the patient was in the hospital, fever therapy was employed four times, with typhoid vaccine given intravenously (each reading 102 F) with no effect On June 4 the patient started soaking one finger in hot tobacco juice Within three days the swelling had gone and the finger had so improved that the patient was encouraged to soak the right hand Treatment has been continued in the following manner The tobacco is boiled for two minutes in water The hands are soaked in the heated extract for thirty minutes, four to six times a day The solution should be as warm as the patient can tolerate without burning

DISCUSSION

DR S W BECKER I think that the disease in all these patients is of the acrodermatitis continue type rather than the pustular psoriasis type The woman with the lesion on the arm shows a definite atrophy following healing, which rules out psoriasis The results from the bizarre treatment are certainly remarkable

DR F E SENEAR We have had this subject up here so often that nearly everything is repetitious I would like to agree with Dr Becker that the disease in these cases, at least the cases of extensive disease, is of the acrodermatitis continue type rather than pustular psoriasis I think that anyone would point out these lesions on the forearm as being a point against acrodermatitis continue, but the lesions on the tips of the fingers with the extensive undermining of the periphery are suggestive of the Hallopeau type

DR ROBERT M B MACKENNA, London, England (by invitation) I agree with everything Dr Senear has said Most of my colleagues would regard these as acrodermatitis continue type of lesions and not pustular dermatitis

DR STEPHEN ROTHMAN The patient started this treatment on her own She heard about it from neighbors The tobacco is boiled for two minutes only Our main purpose in showing these patients was to ask the members of this society to send more patients to us for testing the efficacy of this method with fractions of the tobacco juice in order to isolate the active compounds Of course, we shall need a number of patients with pustular psoriasis and with acrodermatitis Hallopeau to carry out this work

Lipomelanotic Reticulosis (Pautrier-Woringer Disease) Presented by DR STEPHEN ROTMAN and (by invitation) DR M J SCHERBER and DR E L LADEN

R L, aged 63, was admitted to St Joseph Hospital in Chicago on April 30, 1947, with the complaints of swelling, redness and weeping of the skin of the

entire body of one year's duration This ailment started with a pruritic dermatitis on the ankles and elbows, which the patient attributed to contact with brick and lime dust In a few months it had spread to involve the entire body He was treated with local applications and injections with only temporary relief During the first six months of the illness the patient lost 26 pounds (12 Kg) in weight

In March 1947, the patient suffered an acute abdominal episode, which was interpreted as thrombophlebitis of the mesenteric veins, followed by generalized peritonitis

On admission to the hospital in April, there was diffuse erythema, swelling and oozing of most of the body The face and large flexures displayed lichenification Pruritus was intense There was generalized lymphadenopathy with single, hard, enlarged lymph nodes The tongue was beefy red and infiltrated, grayish plaques were present between the soft and hard palate The patient was afebrile

The acute manifestations of the dermatitis were checked by local applications When the patient was seen by the consulting dermatologist at this time the impression was erythroderma due to some lymphoblastomas

Laboratory examinations revealed negative serologic reactions, normal urine, erythrocytes 4,000,000, hemoglobin 10 5 Gm and leukocytes 21,000, with 69 per cent polymorphonuclear cells, 13 per cent lymphocytes, 9 per cent eosinophils, 2 per cent monocytes, 1 per cent basophils and 6 per cent stab cells Plasma proteins were 6 5 Gm per hundred cubic centimeters, albumin 2 8 Gm and globulin 3 7 Gm per hundred cubic centimeters with a ratio of 1 1 3 Sternal puncture showed hyperplasia of neutrophil precursors and a decrease in percentage of erythroblasts The left shift of neutrophil precursors was not pronounced enough to permit a diagnosis of myelogenous leukemia It was thought to be a leukemoid reaction Biopsy of the skin and lymph node was performed The microscopic skin sections showed chronic inflammation with a great number of melanophores and large pale cells with vesicular nuclei In the lymph node specimen the cortex is infiltrated by large pale cells, eosinophils, numerous pigmented cells and some polymorphonuclear and plasma cells

During his hospital stay the patient had two attacks of septic thrombophlebitis with positive blood cultures of hemolytic Staphylococcus albus, each time recovering *after penicillin and dicumarol® therapy*

The pruritus was greatly relieved by roentgen irradiations Several blood transfusions were given

During the observation period there has been a conspicuous darkening of the skin leading to the now prevailing color shade The leukocyte count has varied between 10,000 and 25,000 The relative lymphocytopenia has become progressively worse, down to 6 per cent lymphocytes with 88 per cent polymorphonuclear cells and a leukocyte count of 17,200

DISCUSSION

DR HAMILTON MONTGOMERY, Rochester, Minn I wonder whether a new name is needed or whether this should be called a new disease One sees deposition of melanin pigment in the lymph nodes in a great many inflammatory conditions, in association with lymphoblastomas, in psoriasis and also in conditions in which there is excess pigment in the skin In the case presented today the second biopsy simply revealed a nonspecific dermatitis, in other words, this man had an exfoliative dermatitis or generalized erythroderma without evidence of lymphoblastoma There is increased pigment in both the skin and the lymph nodes

DR ADOLPH ROSTENBERG JR (by invitation) As I understand this term, it does not really designate a cutaneous diagnosis It is purely a pathologic term

this "transitional" variety, they may merely be cases undergoing a single transitory tuberculoid reaction In reply to Dr Montgomery's query regarding sarcoid I was not aware that the lepromin test was necessarily negative in sarcoid, or at least in sarcoid not due to leprosy It had been my feeling that in areas where leprosy was not endemic, positive reactions to lepromin would be relatively unusual and that many cases of sarcoid would therefore, in such areas, be fairly likely to have negative Mitsuda reactions—permitting tuberculoid leprosy to be excluded with fair accuracy This situation does not exist in Hawaii, or in any place where leprosy is endemic However, if anergy in sarcoid is expressed in a negative reaction to lepromin as well as in a negative reaction to tuberculin, the problem is greatly simplified In answer to Dr Weidman, I believe that *Nachtblau* cannot be purchased at the present time, but Dr Reenstierna has promised to give me a small quantity of it, and perhaps some more can be obtained through him at the University of Uppsala in Sweden As to the Fite technic, Fite himself has virtually abandoned it in favor of the Feraca procedure, which is certainly far simpler and more rapid and which he believes is equally satisfactory for finding rare organisms My colleague Dr Tilden and I still prefer to see blue-black bacilli against a pale orange-yellow background

clusive toward allying this entity with urticaria They attest to the efficacy of parathyroid extract used in conjunction with calcium in the former, compared with the mediocre results in the latter

SUMMARY

The failure of the antihistaminic or antiallergic agents to influence lichen urticatus favorably is presented as further evidence to disprove any connection of this condition with urticaria

FATE OF CENTRAL NEVUS IN LEUKODERMA ACQUISITUM CENTRIFUGUM

MORRIS LEIDER, M D
BROOKLYN
AND
ALEXANDER A FISHER, M D
WOODSIDE, N Y

MOST accounts of leukoderma acquisitum centrifugum do not make clear what, if anything, ultimately happens to the central hyperpigmented spots that make this condition so distinctive Neither Sutton,[1] who originally described the picture minutely after Hyde [2] had noted it, nor Leider and Cohen [3] in their recent review discussed the eventual disposition of the moles However, a few of the intervening observers,[4] particularly in the foreign literature, remarked that the central pigmentations sometimes disappear To quote one, Kuske[4c] wrote that " one gets the impression, from history and objective finding, that in some of the lesions undergoing enlargement, the nevus in the center is gradually obliterated by the depigmenting process "[5]

In 1 of Sutton's 2 original cases, the mother of the patient (a child), stated that the central spot had not been present before the onset of the depigmentation In consequence of such observations on the part of patients or their close relatives, some authors have theorized that the pigmented areas in the centers form because melanin, or propigment, drains from the periphery into a centripetal concentration We doubt that these observations are correct and that the resultant theory is

HEREDITARY ANHIDROTIC ECTODERMAL DYSPLASIA

A Clinical and Pathologic Study

BETTE Y UPSHAW, M D
Fellow in Dermatology and Syphilology, Mayo Foundation
AND
HAMILTON MONTGOMERY, M D
ROCHESTER, MINN

THE SYNDROME of hereditary anhidrotic ectodermal dysplasia, which has as its most prominent characteristics anhidrosis, hypodontia or anodontia and hypotrichosis, is one of a group of approximately 200 primarily cutaneous congenital abnormalities that are described in Cockayne's [1] extensive study of this subject Of this group, the following five types of abnormalities were studied and described by one of us (B Y U) in a Mayo Foundation thesis, "Congenital Ectodermal and Mesodermal Dysplasias, A Clinical and Pathological Study" (1) anhidrotic ectodermal dysplasia, (2) hidrotic ectodermal dysplasia, (3) erythroderma ichthysiforme, (4) pachyonychia congenita and (5) Ehlers-Danlos syndrome

In our experience, each and all of these five types of abnormalities can well be called rare, less than 40 patients affected by them have been encountered at the Mayo Clinic in the past twenty-seven years This paper will be confined to the study of the 4 patients affected by anhidrotic ectodermal dysplasia observed at the clinic since 1920

Although, according to Darwin,[2] a description of this syndrome was given by Widderburn [3] in 1838, the term "congenital ectodermal defect" was not used until a case was reported by Christ [4] in 1913 Later observers also used this term until Weech [5] in 1929 designated the

true Nevertheless, the possibility led Niles[6] to attempt cure of the condition by extirpation of the central spots in the hope of interrupting the assumed attraction of pigment thereto Niles reported failure to influence the depigmenting process by this means Nor did the central pigmentations tend to recur, as one would expect they possibly would if the theory of centripetal drainage of pigment had any virture Moreover, in undisturbed cases, the central nevi or hyperpigmentations according to this theory, should grow larger for as long at least as the process is active This situation we believe and will show does not exist

Leider and Cohen,[3] among many others before them,[7] maintained that leukoderma acquisitum centrifugum is nothing more than banal vitiligo that starts accidentally, or for the particular but unknown reason that causes all depigmentation, around preexisting moles Kuske,[4c] who was previously quoted, expressed disagreement in the following words " Sharply delimited, round or oval, depigmented spots without a visible nevus can readily be confused with true vitiligo At present it appears to me that a distinction [between Sutton's phenomenon and vitiligo] is justifiedly made "[8] Kuske based his conviction on a table of clinical differences which we do not find persuasive

In support of the contention that leukoderma acquisitum centrifugum is merely a variant of simple vitiligo, we report by photographs the following instances of spontaneous disappearance of the central maculopapules while the patients were under prolonged observation We never saw nevi come into being, nor could the patients assert that the nevi had not been present long before the depigmentation had begun We noted established vitiliginous areas increase in size both centrifugally and centripetally, i e, away from and into the hyperpigmented centers and we saw new depigmentations begin around other old nevi The nevi seemed to be invaded by the depigmenting process and were gradually blotted out We can make nothing more of this phenomenon than the usual progression of vitiligo The central hyperpigmented areas persist only so long as it takes the depigmenting mechanism, whatever it may be, to bleach them completely The reason that it takes as long as it

group as "the anhidrotic type of hereditary ectodermal dysplasia," a term which we believe to be most descriptive, because it emphasizes both the cause and the most important clinical symptom of the syndrome, inability to sweat

According to recent reviews of the literature including those of Kaalund-Jørgensen and Christensen [6] and Helweg-Larsen and Ludvigsen,[7] approximately 80 cases of the complete anhidrotic syndrome had been reported prior to 1947 The syndrome has a wide racial distribution, reports having been made from many of the countries of North America, Europe and Asia

Although this triad of symptoms, namely, hypodontia, hypotrichosis and anhidrosis, has been observed many times during the past hundred years, the literature we have read includes no observation of universal anhidrosis that occurred alone This is unusual when one considers that universal aplasia of other single components of the skin, such as hair or pigment to produce alopecia totalis or albinism, respectively, is not infrequent

CLINICAL CHARACTERISTICS

The patients affected by the anhidrotic type of ectodermal dysplasia resemble each other to a remarkable degree because of their unusual facies, which is somewhat suggestive of congenital syphilis and is characterized by high, wide brows, prominent frontal bosses, depressed nasal root and bridge, thick lips with radiating furrows about the mouth, and satyr-like ears

The skin of these patients is unusually soft, thin and feminine Total or almost total lack of sweat gland function under all environmental conditions is the most important physiologic feature, sebaceous gland activity is usually diminished to a variable degree, but apocrine function may be normal The mammary glands may be normal or, as described by Clarke and McCance [8] as well as others, they may be deficient or absent

A delayed appearance and a marked deficiency of development of scalp hair eyebrows and eyelashes and lanugo are frequent, but there is often little uniformity in the degree of development of hair beginning at or after puberty, the beard being more frequently normal, while axillary and pubic hair is either scanty or absent Scalp hair is usually stiff fine and short

does for the central pigmentation to disappear is perhaps that the amount of pigment is so excessive or that nevi resist withering on account of their inherent good capacity to produce pigment Also, it seems to us that the very disappearance of the central pigment in this manner disposes of theories like those of Feldman and Lashinsky [9] and others that leukoderma acquisitum centrifugum is a nevoid disease *sui generis* If one wishes to admit vitiligo as a nevoid anomaly (tardus), then leukoderma acquisitum centrifugum is a nevus, too, but still a variant of vitiligo

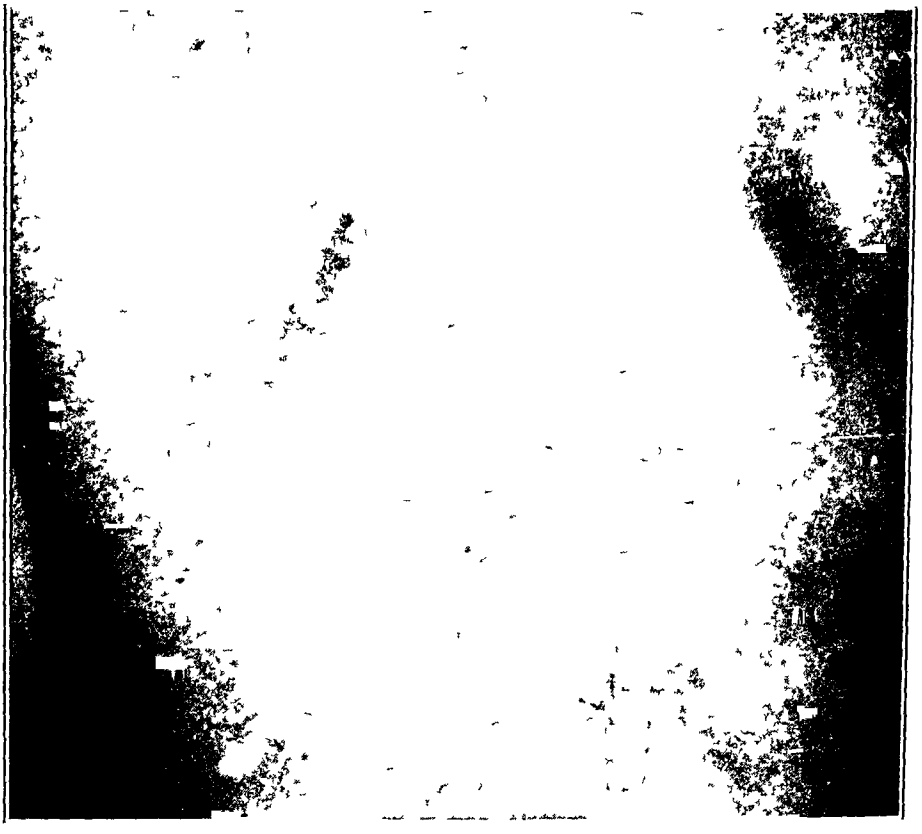

Fig 1 —Leukoderma acquisitum centrifugum, showing lesions with and without central pigmented spots What appears to be residual pigment in some instances is erythema

Figure 1 shows comparable circles of vitiligo, some bearing the central pigmented spots and some lacking them When the patient was first seen by one of us (A A F), almost all lesions bore a nevus Many of these nevi are known, from periodic examination at regular intervals over several years, to have vanished, leaving only the enlarging vitiliginous areas In this case, histologic examination of a site which was

9 Feldman S , and Lashinsky, I M Halo Nevus Leukoderma Centrifugum Acquisitum (Sutton) , Leucopigmentary Nevus, Arch Dermat & Syph **34** 590 (Oct) 1936

The nails of anhidrotic patients are often normal but may exhibit slow growth, longitudinal furrows or slight atrophy

Delayed dentition and hypodontia regularly occur in these patients There is not only a deficiency in number of both deciduous and permanent teeth, but the teeth present are usually abnormally placed and their normal anatomic markings are frequently absent Complete anodontia accompanying anhidrosis has been reported by several authors, including Guilford [9] and Thoma and Allen [10], however, complete roentgenologic proof of anodontia is not given by all of these authors The erupted teeth, particularly the incisors and bicuspids, are often widely separated, peg shaped or conical, darkly pigmented and fragile The development of the maxilla and mandible is in proportion to the number of erupted teeth and usually depends on the amount of resulting mastication made possible, but bony development may be normal in patients with complete anodontia

We have found in the literature no reference to congenital cataracts in connection with this syndrome, although the lens is of ectodermal origin and such an anomaly might be expected Many authors, however, do report deficient function of the lacrimal glands Along with their nasal deformity, many of the patients have chronic rhinitis, often accompanied by nasal discharge of a foul-smelling fluid and diminution of the olfactory sense The glands of the mucous membrane of the nose and throat have repeatedly been found to be deficient in secretory function, producing a decrease in sense of taste, dysphagia, hoarseness and intermittent complete aphonia

Although their anomalies are of ectodermal origin, only rarely have definite defects of the nervous system been found in typical anhidrotic patients It is true, however, that numerous anhidrotic patients have been mentally inferior, but it is commonly believed that the same genetic mutation is not responsible for both of these anomalies

In addition to the aforementioned clinical characteristics which are diagnostic of ectodermal dysplasia of the anhidrotic type, other abnormalities occasionally and probably coincidentally have been associated with it, including skeletal anomalies and dysfunction of the adrenal medulla and the pituitary gland

HISTOPATHOLOGIC CHARACTERISTICS

The majority of observers who have studied excised epidermis from anhidrotic patients have reported either a total absence of sweat glands or the presence of rudimentary fragments of nonfunctioning glands and

marked to have had a preexisting nevus at one time, but from which a biopsy specimen was taken after spontaneous depigmentation had occurred, showed absence of nevus cells and only the negative picture of vitiligo When the central spot is an indisputable nevus rather than an ephelis or lentigo, another nice question is that of what becomes of the nevus cells on disappearance of the mole Are they destroyed or are they dispersed? However that may be, we think that any person with as many lesions as these, some adorned with and some bare of

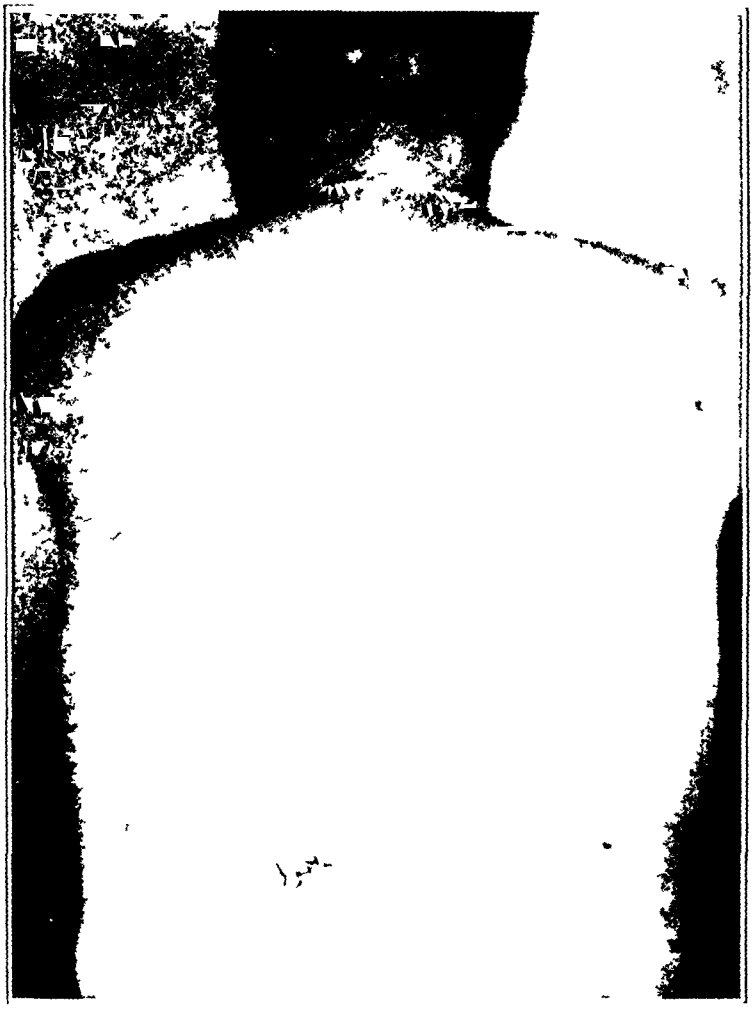

Fig 2—Leukoderma acquisitum centrifugum Compare with figure 1

the central spot, may be assumed to have had more central pigmented maculopapules to begin with, some of which had disappeared by the time the first examination was made This must have been the situation for the patient in case 1 of Leider and Cohen (fig 2) whose photograph shows a nearly identical picture

Figures 3 and 4 are 'before" and after photographs of the patient in case 2 in the article of Leider and Cohen The spontaneous dissolution of the central preexisting nevus was complete What appears in the picture as a pigmented center was erythema, which photographed

ducts There is usually a similar marked deficiency of pilosebaceous structures, but this anomaly is more variable in degree The epidermis is usually thinner than normal, and there is likewise a reduction in width of the cutis, but collagen and elastic fibers and blood vessels are normal in appearance Sunderman [11] reported normal apocrine glands but absent eccrine glands in his biopsy material from the axillas of 2 patients In the anhidrotic patients of Helweg-Larsen and Ludvigsen, as microscopic sections revealed, the number of sweat glands was much reduced, while the glands which were present were hypertrophic

Biopsies of the thin, dry mucous membranes of the mouth and upper respiratory passages have revealed hypoplastic changes in the epithelium as well as in the underlying glands, corresponding with the clinical appearance of these structures

PHYSIOLOGIC CHARACTERISTICS

It must be pointed out that evidence of complete anhidrosis based on single or multiple biopsies is incomplete, even though the sites include the palm or the sole and serial sections reveal no sweat glands Specific physiologic studies of temperature and sweat are necessary for proof of complete anhidrosis At ordinary environmental temperatures and at rest, when the sweat glands are not needed to dissipate heat, the amount of insensible perspiration given off by cutaneous transudation of water is quite sufficient to maintain a normal temperature of the body in anhidrotic as well as in normal patients However, at high environmental temperatures, when a temperature of 98 6 F can be maintained in a normal person by the function of sweat glands, the temperature of the anhidrotic patient rises rapidly to extremes of 102 to 104 F , and the pulse and respiratory rates increase proportionately in a vain attempt to dissipate heat

Although the amount of perspiration of anhidrotic patients is inadequate to maintain a normal body temperature at high environmental temperatures, Felsher [12] has observed that some few sweat glands may be present and functioning in these patients By applying a starch-iodine mixture to the skin of his patients, he saw a few small areas where sweat was being produced when the skin was exposed to heat He therefore suggested that the term "hypohidrosis" rather than "anhidrosis be applied to this group of patients

dark In the flesh it was red and it would show so on a color photograph The interim was eighteen months, and during this period the gradual progressive depigmentation had been noted on several occasions In both of these cases in which we were able to follow the extinction of the nevi, we saw that as the pigmentation faded it left erythema, which then eventually blanched and blended into the surrounding pallor of the vitiligo In addition, whether the original

Fig 3 —Leukoderma centrifugum acquisitum, beginning

pigmented spot was a macule or a papule, the end result was always flat and level with the neighboring skin

It may be argued that the central hyperpigmentations in leukoderma acquisitum centrifugum first come into being because melanin drains to the center, thus forming the moles, and that they then get involved by the "vitiligizing" process which erases them We remember no report in which a medical observer claimed to have witnessed the first event of nevus formation Therefore, it appears much more likely to us that nevi, lentigines and ephelides, which are so common to all, preexist or arise in the ordinary mysterious manner Whenever they come into

ETIOLOGIC FACTORS

Because of the facial similarity of anhidrotic patients and patients with congenital syphilis, clinicians formerly believed the cause of the anhidrotic syndrome to be congenital syphilis Still others explained the syndrome on the basis of endocrine dysfunction, but it now appears that all etiologic concepts other than those of heredity have been disproved

The first anhidrotic patients described by Widderburn,[3] were 10 male members of a Hindu family, and although many patients have been reported who gave absolutely no family history of abnormalities, the majority of patients have ancestors with similar anomalies When the full syndrome is not found in other members of the family, several of them will often have one or more of the component anomalies, except anhidrosis, that comprise typical anhidrotic dysplasia

The exact mode of genetic transmission of the full anhidrotic syndrome has been the subject of controversy since the first cases were encountered It was noted early that males are affected much oftener than females, of the first 60 patients, only 8 were females, according to Kaalund-Jørgensen and Christensen,[6] who also listed 7 instances in which the typical syndrome occurred in siblings Wechselmann concluded from his studies that the defect was transmitted as a sex-linked characteristic, in the same manner as hemophilia, by an unaffected female conductor to affected male members of the family [13] Goeckermann,[14] in a report on a female patient, pointed out that the syndrome was not always recessive in females As more and more cases were reported, it became obvious that the mode of genetic transmission is not identical in all patients Geneticists now emphasize that one peculiarity of human genetics is that the same abnormal character may be sex linked, dominant or recessive in different families, and there are now reports in the literature of the genetic transmission of the complete anhidrotic syndrome by each of these modes of inheritance

PATHOGENIC FEATURES

Although the time and mode of production of the anhidrotic syndrome constitute a subject of much speculation, little detailed information is known

The relative order of normal embryologic development of the dermal appendages which are involved in the syndrome is as follows 1 The hair develops from downgrowths of the epidermis which appear

13 Wechselmann, W, and Loewy, A Untersuchungen an drei blutsverwandten Personen mit ektodermalen Hemmungsbildungen, besonders des Hautdrusensystems, Berl klin Wchnschr **2** 1369-1373 (July) 1911

14 Goeckermann, W H Congenital Ectodermal Defect, with Report of a Case, Arch Dermat & Syph **1** 396-412 (April) 1920

being during life they tend to be permanent They may, relatively rarely, disappear as a result of trauma or other uncertain reasons In leukoderma acquisitum centrifugum they seem to be invaded by the same depigmenting process that concurrently affects the ordinary skin

F Parkes Weber [10] speculatively suggested that there may be a constant law embracing the phenomenon of depigmentation of this sort,

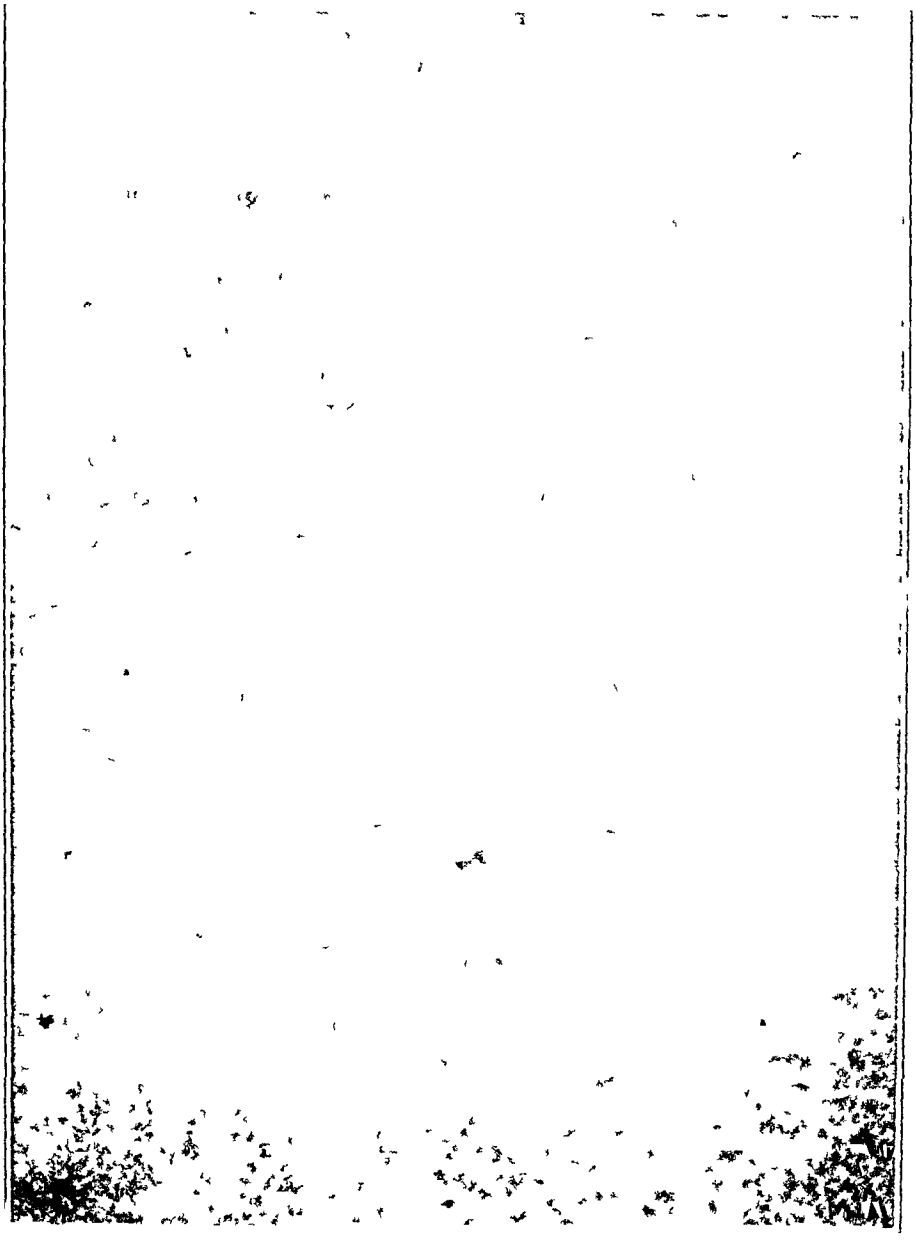

Fig 4—Same case as in figure 3, about eighteen months later The darker portion in the center is erythema, not pigment

as follows Nevi predispose to circumferential depigmentation in an amount that is in direct proportion to their size Stokes [7d] noted, and we have too that leukoderma acquisitum centrifugum is rather common

10 Weber F P A Law Regarding the Distribution of Pigmented (Leucodermic) Patches of Vitiligo, When They Are Superadded to Mole-Like Nevi Brit J Child Dis **21** 202, 1924

between the second and third months of gestation, first in the region of the eyebrows and forehead Between the fourth and fifth months, rudiments of hair begin to grow from these follicles 2 The earliest evidence of nails appears during the third month, but formation of the nail matrix occurs later, at the fifth month of gestation 3 Sebaceous glands originate as lateral outgrowths of the hair follicles during the fifth month 4 Sweat gland anlages appear first on the tips of the phalanges between the fourth and fifth months, and on the proximal portion of the extremities and the trunk by the end of the sixth month, development of these glands is almost complete before birth

The remainder of the embryologic data concerned in the syndrome is as follows 1 The teeth have a double origin, the enamel organ develops from the ectoderm, and the dentine, pulp and cement develop from the mesoderm By the seventh week of gestation, the dental lamina of the ectoderm shows circumscribed thickenings where the future teeth are to be formed At eight weeks, the underlying mesodermal cells begin their growth and differentiation to form the future mesodermal portion of the teeth 2 The milk ridge appears in the embryo between the fifth and sixth weeks of intrauterine life, and from it, in the pectoral region, papilla-like anlages of the mammary glands develop early in the fifth month 3 The neural tube, from which the entire nervous system, the adrenal medulla and a portion of the pituitary gland develop, is completely closed and separated from the overlying epidermis by the beginning of the second month of gestation

Since few reports of definite abnormalities of the nervous system in anhidrotic patients have been recorded, it seems probable that the pathologic process resulting from the defective gene or genes begins to affect the development of the epidermal structures during the second fetal month However, the lens, although undergoing separation from the ectoderm during this time, enjoys, to our knowledge, complete immunity Although the mechanism of genetic transmission of these defects is fairly well understood, at this time the method by which certain structures appear to be haphazardly affected by these genes is not at all clear

Most observers have agreed that the pathologic process is probably an aplasia and not an atrophy because degenerative changes in ectodermal structures rarely have been seen in tissue sections, the structures instead appear never to have begun or just barely to have begun to differentiate

DIFFERENTIAL DIAGNOSIS

There are four diseases which usually have enough symptoms in common with the anhidrotic syndrome to be considered in its differential diagnosis The accompanying table is a brief summary of their essential similarities and differences

if sought for and that non-nevoid conditions, like the lesions of psoriasis, syphilis, Boeck's sarcoid and burns, are frequently surrounded by leukodermatous halos, and he therefore postulated that a common physicochemical inhibition of melanogenesis is at the basis of all such depigmentations It seems to us that hyperpigmentations too are common around many dermatoses, including those mentioned by Stokes, none of which is commonly associated with problems of melanogenesis Coupling our own observations with those of Weber and Stokes, we should say that there may be a law about pigmentary dyscrasia which may be formulated as follows Any abnormality of the skin, congenital or acquired, perceptible or imperceptible, may become a locus of pigmentary disturbance in directions of excessive formation and concentration or of inadequate formation and dispersion When the disturbance is in the direction of depigmentation, is imperceptible and is of point source and unknown cause on apparently normal skin, the clinical picture appears like that of banal vitiligo When the predisposing disturbance, again in the direction of depigmentation, is an obvious lesion, then the clinical lesion may be leukoderma acquisitum centrifugum, with either a nevus or some other non-nevoid condition in the center In the latter event, the word leukoderma is a most proper designation because the depigmentation is related to a known proximate cause In reverse, the very same types of pigmentary disturbances may in other cases eventuate in chloasma-like changes Indeed, vitiligo itself often seems to be accompanied with hyperpigmentation at its border, which observation supports a concept of melanogenesis as a mechanism of such delicate balance that the very same influence, or train of influences, seems to be able to direct it into the direction of either hypopigmentation or hyperpigmentation or of both simultaneously

4514 Forty-Eighth Street

TREATMENT

Treatment of anhidrotic patients is largely symptomatic because of the fundamentally aplastic lesions of the syndrome, but certain therapeutic principles should be emphasized to the patient or to the parents of an anhidrotic infant The limiting effect of the anhidrosis on the mode of living must be well understood, the genetic transmission of

Differential Diagnosis of the Anhidrotic Syndrome

	Anhidrotic Ectodermal Dysplasia	Hidrotic Ectodermal Dysplasia	Werner's Syndrome	Rothmund's Syndrome	Progeria, Hutchinson Gulliford Type
Genetic transmission	Dominant, recessive or sex linked	Usually dominant	Usually recessive	Usually recessive	Not proved
Age at onset of symptoms	First year	First year	20 to 30 yr	1 to 5 yr	1 to 5 yr
Facies	Inverted pyramid, frontal bosses, depressed nasal bridge	Not characteristic	Senile changes, beaked nose, small mouth and chin	Not characteristic	Frontal bosses, beaked nose, retracted chin
Skin	Dry, soft, feminine	Hyperkeratoses of palms and soles, oriental pigmentation	Epidermal, subcutaneous and muscular atrophy of distal extremities with trophic ulcers	Atrophy, brownish pigmentation, telangiectases	Atrophy of epidermis, subcutaneous tissue and muscle
Sebaceous glands	Markedly decreased	Slightly decreased	Normal	Normal	Normal
Sweat glands	Decreased or absent	Normal	Normal	Normal	Normal
Mammary glands	May be absent	Normal	Normal	Normal	Normal
Hair	Generalized alopecia, usually subtotal	Generalized alopecia, always subtotal, fragile hair	Canities and premature alopecia	Usually normal	Premature alopecia
Nails	Normal	Short, thick, elevated tip	Normal	Normal	Short, fragile
Teeth	Decreased or absent, also deformed	Normal	Normal	Normal	Irregular development
Eyes	Normal	Normal	Juvenile cataracts	Juvenile cataracts	Normal
Systemic abnormalities					
1 Cardiovascular	Distinct intolerance of heat	None	Early arteriosclerosis	None	Early arteriosclerosis
2 Skeletal	None	Usually none	Short stature, osteoporosis	Occasionally short stature and small hands and feet	Dwarfed trunk and extremities, joint deformity
3 Endocrine	Usually none	Pituitary and suprarenal deficiency (?)	Hypogonadism, diabetes	Occasional hypogonadism	Hypogonadism
Prognosis for life	About average	Average	Death before age of 40 yr	Average	Death before age, of 30 yr

the defect should also be explained, and no assurances should be given to the parents of an anhidrotic child that future children will be normal

Artificial dentures should be fitted early in anhidrotic children with hypodontia to facilitate the development of the mandible and the maxilla Plastic repair of the saddle nose deformity will likewise do much to improve the patient's facies and general morale Mortimer, Wright

IS LICHEN URTICATUS A FORM OF URTICARIA?

THEODORE CORNBLEET, M D
CHICAGO

SINCE the time of Bateman, who accurately described lichen urticatus, there has been controversy about the nature and pathogenesis of this disorder In successive periods of dermatologic history new ideas have developed about this disease, reflecting the thoughts and subject matters current at the moment Thus, at one period, foods and bowel disturbances were said to be causative, in harmony with the emphasis placed on intestinal putrefactions and toxemias At present lichen urticatus is mostly thought of as a form of urticaria, in keeping with the keen awareness of the phenomena of allergy, and is so classified in the textbooks

There has been so much written on lichen urticatus that there would seem to be little excuse for still further overtaxing what has been for the most part theoretic discussion Only new evidence can be an adequate reason for reopening the subject The recent development and use of the antihistaminic or antiallergic synthetic drugs may permit one to survey the problem from a fresh perspective Toward that end the following several case histories are presented

CASE HISTORIES

1 T K R, a Negro girl 4 years old, had a papular eruption mostly on the extensors of the extremities and a few lesions on the trunk and the face, which was diagnosed as lichen urticatus The mother said it was present the previous two summers, too After three weeks' use of diphenhydramine hydrochloride (elixir benadryl hydrochloride®) there was no improvement in the appearance of the lesions or apparently in the distress caused by the itching There was marked betterment after three more weeks during which she was treated simultaneously with parathyroid injection U S P and calcium lactate

2 Z P, a boy 5 years old, had an eruption which had been present in the same form the previous year It was thought to be lichen urticatus Four weeks' use of diphenhydramine hydrochloride failed to produce any evident improvement in the lesions, even though the child slept better and was more restful

3 J O M, a woman 23 years old, had a pruritic papular eruption on the extensors of the arms and legs and scattered elements on the trunk Some of the lesions were acuminate and there was severe pruritus There was no grouping, nevertheless, she was given a course of sulfapyridine treatment on the pos-

From the Department of Dermatology University of Illinois College of Medicine, Service of Dr I E Sonear

and Collip[15] have reported favorably on the results of using estrogenic substances incorporated in a nasal spray in treating anhidrotic patients for chronic rhinitis or ozena In view of the normal longevity enjoyed by the patients affected by anhidrosis, the aforementioned measures, although not curative, are certainly important in making life more pleasant

REPORT OF CASES

CASE 1.—A white boy, 7 weeks of age, was brought to the clinic during warm weather because of intermittent fever that had been present since 2 weeks of age The baby weighed 6 pounds 8 ounces (2,950 Gm) at birth and appeared normal Except for the fever of unknown origin, there were no symptoms of illness The family history revealed numerous congenital abnormalities, none of which could be related to the anhidrotic syndrome The child had no siblings, and there was no history of intermarriage of relatives

In the physical examination the only abnormal findings were absence of eyelashes and eyebrows, and very dry skin over the entire body In the hospital it was noted that the child never perspired and that his temperature increased directly in relationship to the external environment After fifteen minutes under a heat cradle, the rectal temperature rose from normal to 100 F, increases in temperature were noted after each meal No teeth were visible on roentgenologic examination Routine laboratory investigations revealed moderately severe hyperchromic anemia A biopsy specimen was removed from the sole of the left foot, and the multiple sections studied revealed complete absence of sweat glands and ducts, the epidermis and cutis being normal in other respects

Four years later the mother said that no sweating had ever been noted and that by living in the basement during hot weather he had been quite comfortable and able to maintain a normal temperature At 18 months of age he had two pointed teeth which were still present and strong at the age of 4 years His scalp hair was white sparse and slow growing, he had normal eyelashes but no eyebrows The mucous membrane of his nose was dry and crusted, and he had had several severe laryngeal infections, one of which had necessitated tracheotomy His mental development was thought to be normal

CASE 2.—A white boy, 2 years old, was brought to the clinic from a warm climate by his paternal grandmother who said that since shortly after the birth of the child it had been noted that his temperature rose when he was placed in a warm environment The patient weighed 5 pounds (2,270 Gm) at birth, six hours after this event his temperature reached 106 F Fever continued almost constantly during the first summer, and no cause could be found When cool weather began, the child's temperature returned to normal, but it began to rise on the first warm day of the following year His pupils had been dilated since birth, they did not become smaller in the bright sunshine, and photophobia was obvious The child had had eczema of scalp, hands and feet since 6 months of age, and this was much more severe in warm weather When the teeth appeared, they were brown and fragile and soon became carious At 1 year of age, eight teeth had developed The nails had been normal until 1 year of age, when they became rough and scaly The child sat alone at 8 months and walked at 18 months

15 Mortimer, H, Wright, R P, and Collip, J B Atrophic Rhinitis The Constitutional Factor, And the Treatment with Œstrogenic Hormones, Canad M A J **37** 445-456 (Nov) 1937

sibility that the eruption was dermatitis herpetiformis There was no good effect from this therapy She was then given 300 mg of tripelennamine hydrochloride (pyribenzamine hydrochloride®) daily for ten days without visible or subjective improvement Itching largely subsided and much of the eruption was gone after a month of the use of parathyroid injection U S P and calcium lactate

4 D A, a white boy 8 years old, had a papular eruption mostly on the extensor surfaces of the extremities A few lesions had puffy bases, and a frank wheal was present at one site There was itching He was thought to have lichen urticatus The lesions remained largely unchanged after two weeks' use of diphenhydramine hydrochloride

5 C N, a Negro girl 6 years old, had an itching eruption which was believed to be lichen urticatus Three weeks' use of diphenhydramine hydrochloride effected no apparent improvement in her cutaneous condition

COMMENT

The greatest success attending the use of the antihistaminics has been in connection with urticaria It is reasonable to assume that if lichen urticatus is a form of urticaria peculiar to children it should react somewhat similarly to therapeutic agents which benefit patients with urticaria This small series of patients derived no benefit from the newer antiallergic agents in contrast with the happier results commonly seen in ordinary urticaria This raises again doubts that lichen urticatus is primarily an urticarial process Pruritus is common to both, but is present, too, where there is no suspicion of urticaria The mere presence of wheals as one of the primary lesions should not be binding to a diagnosis of urticaria It would seem tenuous to make their presence in urticaria pigmentosa a proper cause for including the latter among the urticarias even though its origin remains unknown Wheals may at times be found in diverse entities, even as the initiating event of a folliculitis or a furuncle

Walzer and Grolnick,[1] in an intensive study of lichen urticatus, employing modern methods of dealing with allergy, were unable to relate this disease to such a process Pillsbury and Sternberg [2] said

> the theory that the nature of this disease is allergic has been commonly held, and most investigations have been concerned in the attempt to prove or disprove this contention We believe that the evidence supporting such a view is extremely meager and that further study along the lines of allergy, unless some unique approach is devised, will probably be fruitless

They reviewed the studies of various authors whose work had failed to resolve the beclouded pathogenesis of lichen urticatus and been incon-

1 Walzer, A, and Grolnick, M Relation of Papular Urticaria and Prurigo Mitis to Allergy, J Allergy **5** 240, 1934

2 Pillsbury, D M, and Sternberg, T H Lichen Urticatus (Papular Urticaria) Treatment with Parathyroid Extract, Theoretical Consideration of Etiology, Am J Dis Child **53** 1209 (May) 1937

The family history revealed no congenital abnormalities, but the patient's paternal great-grandfather and maternal great-grandmother were brother and sister The patient's one sibling, a sister of 8 months of age, was said to have the same abnormalities of eye and temperature as were noted in the patient

On physical examination, the child appeared to be well developed and nourished The facies and the hair distribution were not unusual, but the skin was dry, and no sweating was noted No eczematoid lesions were present, and the teeth and nails were as described The pupils were equal and semidilated and did not react to light Pupillary dilatation did not occur after local instillation of homatropine hydrobromide nor constriction after instillation of physostigmine salicylate or a pilocarpine salt There were pupillary remnants in both eyes, and the fundi were normal The remainder of the physical examination revealed no significant findings, and the laboratory examinations gave essentially normal results

Further observations of the child revealed that his temperature increased after eating and with crying but could be easily controlled by sponging him with cool water After administration of pilocarpine there was flushing of the face, neck and breast down to a sharp line at the nipple level, but no sweating occurred Biopsy of the skin was not performed

When the patient was 5 years old, the grandmother stated that he still was intolerant to heat, that there was no change in his pupils and that his deciduous teeth were black stumps except his six year molars, which appeared normal No sweating had ever been noted in the patient's younger sister, and although she had a complete set of deciduous teeth, they were darkly pigmented and sensitive to sweets, heat and cold

CASE 3.—A white man, 26 years of age, unmarried, working as lifeguard, first came to the clinic during warm weather because of lack of perspiration, scanty growth of hair and abnormal dentition These abnormalities had been present since birth, and the father stated that the patient's abnormalities were familial in character, originating many generations ago in the patient's mother's family, always appearing in one male of each generation and completely absent in the women of the family as far as he knew

Physical examination revealed a well nourished man of average adult size, the ears were protuberant, the root of the nose was depressed and the septum was irregular, but there was no widening or saddle nose deformity The skin was soft and dry On the scalp there was only a sparse peripheral fringe of hair, there was little lanugo over the trunk and extremities, and only a few small tufts of hair in the pubic and axillary regions Two teeth were present, one of which was a small tag There was moderate atrophy of the mucosa of the nasopharynx, pharynx and larynx, but the voice was normal

Biopsy and other laboratory procedures were not performed until the patient was admitted to the clinic a second time, five years later Then it was found that after strenuous physical exercise the rectal temperature increased 2 degrees F His basal metabolic rate was normal on two occasions, but after strenuous exercise it increased to + 40 per cent, while the metabolic rate of the normal control person increased to + 20 per cent After his second admission, histologic examinations were made of skin tissues removed from the right axilla and the lower right part of the thorax, in the serial sections no trace of hair follicles, sebaceous glands, sweat glands or apocrine glands could be found

CASE 4.—A 23 year old unmarried farmer came to the clinic because of weakness of the arms and legs and loss of consciousness, usually occurring just preceding a meal or several hours afterward These symptoms began suddenly during one hot day of the preceding summer and continued to recur during cooler weather He

Hurwitt (*J Invest Dermat* **5** 197 [Aug] 1942) reviewed all the lymph nodes taken out at the Mount Sinai Hospital, New York There is a reticulum and histiocytic cell replacement of the lymphocyte in the lymph node It is purely a benign process and is not related to lymphoblastoma Hurwitt also criticized the term Pautrier-Woringer disease and used the name dermatopathic lymphadenitis About a year later there was an article by Larkin and his co-workers (*J Pediat* **24** 442 [April] 1944) on this same syndrome, with reference particularly to infantile eczema He pointed out that involvement of the lymph nodes is not uncommon in infantile eczema and that these nodes can have a resemblance to those seen in Hodgkin's disease He warned against confusion with manifestations in Hodgkin's disease because this condition is benign

DR S W BECKER I have been of the opinion that this reaction was of a nonspecific variety Someone, some months ago, said that the pathologist at Cook County Hospital considered it a definite entity

DR S M BLUEFARB The original article on lipomelanotic reticulosis was written by Pautrier and Woringer in 1932 (*Bull Soc franç dermat et syph* **39** 947, 1932) They described 6 cases in which the three cardinal signs were exfoliative dermatitis, superficial generalized lymphadenopthy and pigmentation of the skin At that time no specific causative factor was mentioned In a second communication in 1940 Pautrier and Woringer described a case of generalized erythroderma in which typical lesions of mycosis fungoides developed and in which the original lymph node biopsy showed the appearance of lipomelanot c reticulosis and a subsequent one a reticulum cell proliferation found in mycosis fungoides They suggested that there might be a causal relationship between the two conditions At the February 1945 meeting Dr Oliver (ARCH DERMAT & SYPH **54** 621 [Nov] 1946) showed a case of generalized erythroderma with lipomelanotic reticulosis Several months later the patient died of mycosis fungoides

There appear to be several schools of thought regarding the outcome of this disease Dr Rostenberg just mentioned the benignity of this disease I believe that Robb-Smith of England also favors the concept of a benign condition as the patients in the 3 fatal cases in his series appeared to die from intercurrent disease rather than from the skin condition (*Brit J Dermat* **56** 107 [May-June] 1944) However, I do not believe that the disease in all these cases can be considered benign and that one should give a guarded prognosis because in a certain percentage of these cases one of the lymphoblastomas will develop

DR STEPHEN ROTHMAN I share the skeptic attitude of Dr Montgomery concerning the assumption that this is a separate entity On the other hand, the microscopic picture of the lymph nodes is not one of banal chronic inflammation, because the infiltration is invasive, neither does the picture correspond with that of any of the known lymphoblastomas When first seen, this patient had erythroderma with lichenification

Mycosis Fungoides Treated with Sodium Paraaminobenzoic Acid Presented by DR JAMES H MITCHELL

Mrs L McC, aged 52, was presented at the meeting of May 21 At the suggestion of Dr Arthur Curtis, treatment with sodium paraaminobenzoic acid was begun March 29, 1947 Tablets of 2 Gm were taken every three hours during the waking hours The clinical improvement was at first spectacular, but there has been little change in her condition in the past month

DISCUSSION

DR JAMES H MITCHELL The patient was shown last month, and I asked her to come here especially for examination by Dr MacKenna I might say that since she was last presented she has made less progress than she made previously Dr Ormsby pointed out that many different medicaments could improve mycosis fungoides temporarily, and perhaps this medicament will fit in with what Dr Ormsby has said I have another patient treated by the same method and a third one with leukemia It remains to be seen whether we have anything worth while

NOTE—The patient with lymphatic leukemia died without making a satisfactory trial of the medicament The other 2 patients are still doing well

A Case for Diagnosis (Alopecia Areata? Atrophic Glossitis? Acquired Anhidrosis?) Presented by DR FRANCIS W LYNCH

Miss G L, aged 24, first had a dermatologic condition at the age of 14, when she had a febrile illness, possibly rheumatic fever, followed by a generalized eruption which was first regarded as scarlet fever The eruption recurred three times, accompanied with fever and followed by exfoliation After the last febrile attack the exfoliation continued, accompanied with pyogenic infection especially on the hands, feet and scalp, resulting in loss of the nails and alopecia There was also otitis, conjunctivitis and gingivitis About that time the skin on the chest and abdomen became inflamed and was wiped off easily, leaving a moist red surface which subsequently healed The patient was bedridden seven months She lost 67 pounds (30 Kg) in weight

Subsequently there has been persistent alopecia which is almost total There is photophobia and a severe refractile error There was amenorrhea for one year, but the menses again became normal During hot weather she perspires slightly and becomes weak, and her temperature rises to 103 F or more

The family history is normal except that one sister had eczema in infancy The patient has had occasional urticaria

The scalp is almost bald, with some occipital hair remaining There are a few hairs in the lashes and brows, the body and extremities are without hair The bulbar conjunctivas are slightly red and the palpebral conjunctivas show some pale areas and other inflamed areas (They previously were treated by electrosurgery) The tongue presents superficial atrophy The left buccal mucous membrane shows an irregular area of thickening and possibly scarring All the nails are atrophic and deformed The palms and soles are dry and appear to be scarred The extremities are smooth and hairless, and the skin of the legs is thin There are numerous irregular brown macules on the face and hands

DISCUSSION

DR S W BECKER This is an odd case It started out at the age of 14 when the patient had a severe febrile reaction, during which she lost her hair I suppose it was on a systemic basis Later she had a recurrence of the generalized eruption, which she said looked like scarlet fever It recurred a great many times She had a severe crusting eruption of the scalp She obviously has a certain amount of cutaneous scarring, which I presume resulted from the inflammatory reaction She lost not only her hair but her finger nails as well Her tongue is somewhat atrophic, and I thought that there was a little leukoplakia on the tongue and buccal mucosa The palms and soles were peculiar in that she had fungated keratoses which were a little suggestive of an arsenical keratosis I questioned

had had no convulsions at any time and had noted no aura prior to loss of consciousness The patient had been told elsewhere that he had congenital absence of the sweat glands, and he had noted heat intolerance all his life He did not relate the onset of weakness or unconsciousness to becoming overheated or to hyperventilation The family history concerning congenital defects did not disclose anything that was significant Two brothers had died in early infancy of unknown causes

Physical examination revealed a young man of average height and weight (fig 1) His forehead was extremely high, his small eyes were widely separated His nose was wide, the bridge being almost flat The lips were thick and muscular, there was total anodontia, and the mandible and the maxilla were underdeveloped, producing a "dish face" deformity

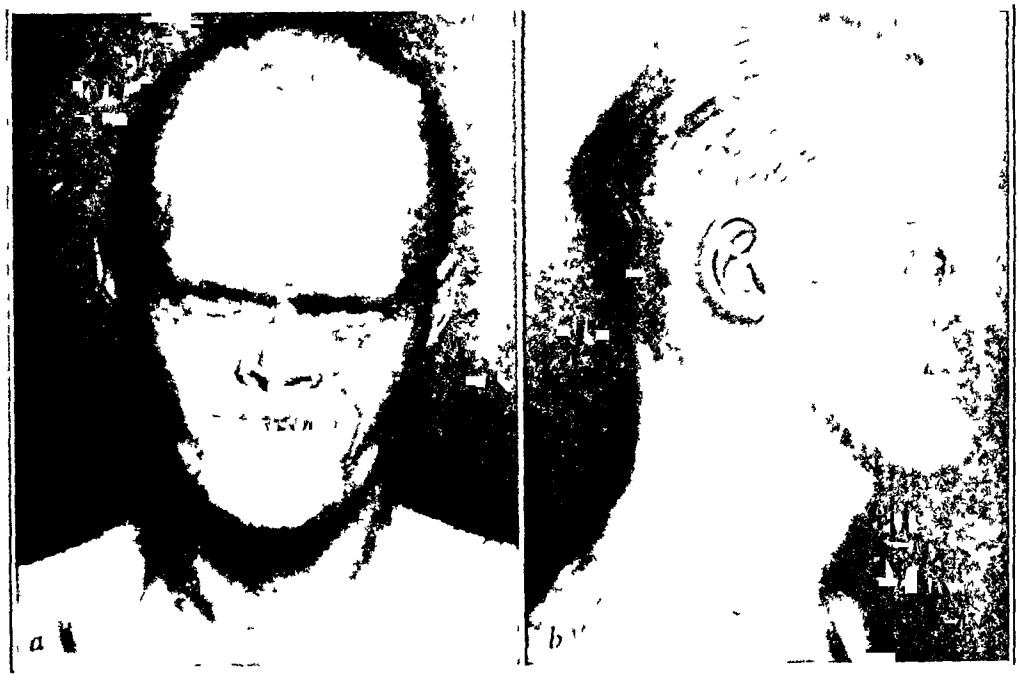

Fig 1 (case 4) —(*a*) Anterior and (*b*) profile views This is the characteristic concave facies of hereditary anhidrotic ectodermal dysplasia Note the sparse growth of hair on the scalp and the normal amount of lanugo in the shoulders

No activity of sebaceous or sweat glands was noted anywhere on the skin, which was excessively dry A diffuse symmetric keratoderma covered the palms, the soles and the nails were normal

There was considerable alopecia of the scalp, most prominent over the vertex The scalp hair present was stiff and dry, and only a few hairs were present anteriorly Eyelashes and eyebrows were absent, and only a few sprigs of hair were present in the axillary and pubic regions The beard was normal, as was the lanugo on the thorax and the shoulders, but lanugo was absent elsewhere

The mammary glands were absent, and there was no pigmentation to mark their usual site No teeth were present The eyes and the lacrimal glands were normal

The thin septum of the nose contained no cartilage, and the mucous membrane was atrophic The senses of smell and taste were intact

by the flea as he bites Or, to put it in other words, a flea may bite, and as a result there may be urticarial lesions at sites remote from the bitten areas

The history is equally important If the sufferer is adult, he is usually new to the Bay region He has been subject to flea bites for only a sufficient period of time to become sensitized by the antigen Most patients suffering from flea bites are children, newly born or newly arrived in the Bay area

Other types of eruptions which are seen more rarely are secondary bacterial infections and other complications of scratching Recurrent

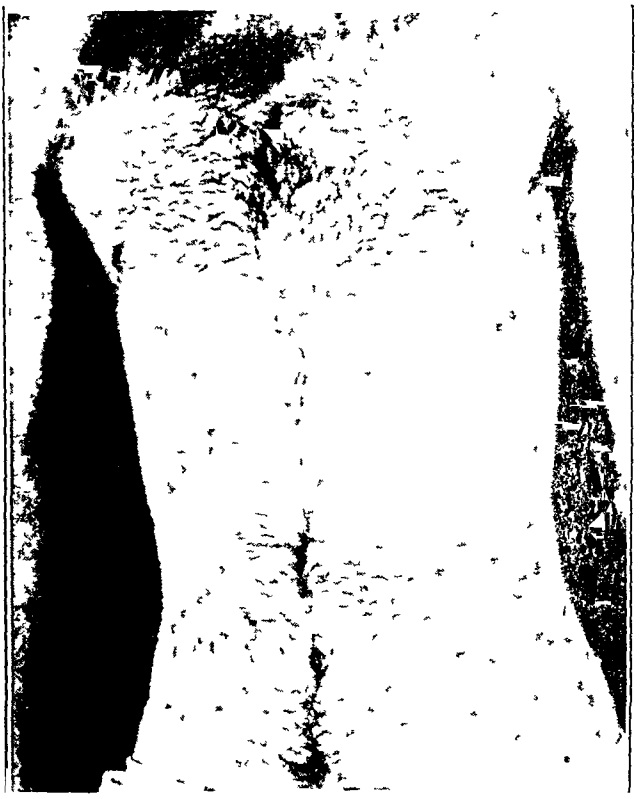

Fig 4—Typical flea bites Note resemblance to papular urticaria (Courtesy of Samuel Ayres Jr, M D, Los Angeles)

furuncles, especially in children, have been observed Less frequently occur bullous eruptions on the lower extremities and generalized, erythema-multiforme-like, bullous eruptions

DIFFERENTIAL DIAGNOSIS

It is the experience of those in our office that most cases diagnosed as "papular urticaria" in our district are in reality examples of flea bites Chipman [4] recognized this fact long ago While my associates and I do

4 Chipman, E D Urticaria, with Special References to the Cause in the Papular Forms of Children, California State J Med 8 207 (June) 1910

Routine examinations of blood and urine gave normal results, as did determinations of the basal metabolic rate and the fasting blood sugar, calcium and potassium Roentgenograms of the skull and the thorax did not disclose any abnormality, and the electroencephalogram revealed mild generalized dysrhythmic activity without localizing signs

Under an electric baker the patient's oral temperature rose from 98 2 to 100 4 F in fifteen minutes After an injection of 5 mg of furfuryl trimethylammonium iodide (furmethide®) flushing and weakness were noted, but no sweat, and no tremor or unconsciousness developed

Fig 2 (case 4) —Section of a biopsy specimen removed from the palm It shows complete absence of sweat glands and ducts (hematoxylin and eosin, × 25)

Biopsy specimens were removed from the skin of the right forearm, right arm and palm of the right hand, in the serial sections no trace of coil glands or ducts was visible (fig 2)

Over a period of several months, three plastic procedures employing cartilage implants succeeded in forming an elevated nasal bridge, so that the patient's appearance was improved Diphenylhydantoin sodium (dilantin sodium®) was prescribed in an attempt to control the episodes of weakness and unconsciousness, the patient was advised to restrict his strenuous farming activities during hot weather

not deny the existence of true papular urticaria of endogenous origin we are certain that it is rare in comparison with the exogenously flea-produced variety Children, particularly, or adults who are newcomers to the Coast are sometimes referred to us by pediatricians or general physicians, with the diagnosis of "hives" The story will invariably be that the patient had not been subject to hives prior to coming to the Coast and that the eruption appeared shortly after arrival here Usually the physician or the patient considers the condition to be an allergy to some of the foods of the West Coast, such as sea foods or fruit It takes a great deal of persuasion for one to convince these patients that the origin of the eruption is not what they are eating but, rather, what is eating them Although this fact is known to all the local dermatologists, it is astonishing that it is not known to all physicians and to the laity

This failure to recognize such a simple, obvious thing as flea bites is not limited to our locality The Jadassohn [5] school in Germany, Hallam,[6] Tate,[7] and Kinnear [8] in England and Urbach [9] in Vienna reported that papular urticaria in children disappeared when the patients were hospitalized and recurred when they returned home Reasoning from this information the English observers [10] and Urbach [9] expressed the conclusion that papular urticaria is an allergic manifestation, the exciting cause of which is something in the home environment, food or bedding These authors made little or no mention of the possibility of fleas or other insects being etiologic factors One of Jadassohn's pupils, Gerard Simon,[5] described a case of prurigo which cleared while in the hospital and had an exacerbation when the patient returned home Hallam [6] quoted Jadassohn to the effect that he had noted many years ago that cases of Hebra's prurigo cleared up when the patients were hospitalized Although the evidence against fleas in these older reports is uncertain, the possibility should be considered In recent reports the evidence against fleas is much stronger Hallam [6] reported a series of patients with papular urticaria whose condition cleared on hospitalization only to relapse on their return to their homes He concluded that papular

COMMENT ON CASES

As in case 1, it is not uncommon for anhidrotic infants who have increased temperature shortly after birth to be extensively and vainly studied for evidence of infections Seldom is the correct diagnosis made in the first few weeks of life, and so the child is not subjected to varied and multiple therapeutic methods In contrast to those in adults, the obvious clues to the correct diagnosis, namely, anodontia and hypotrichosis, are normal findings at this age The typical anhidrotic facies, although observed as early as 1 year of age, is not conspicuous in the first few weeks of life, and in the absence of a history of similar hereditary anomalies, unless the family or the physician notes that the rise of temperature is correlated with the external environment, the diagnosis may be delayed until lack of teeth and hair is noted in the second six months of life In case 1, since the patient fortunately was examined in August, the correlation of high body temperature and high external environmental temperature was noted, when, in further study of this phenomenon, the patient was exposed to a heat cradle and no sweating was produced at an abnormally high body temperature, only the biopsy showing absence of sweat glands on the sole of the foot was needed to confirm the diagnosis The absence of teeth on roentgenologic examination of the mandible and the maxilla was further evidence of the existence of the complete anhidrotic syndrome In the child's subsequent development, the repeated infections of the upper part of the respiratory tract illustrated one of the common complications resulting from the abnormal formation of the mucous membrane

Of particular interest in case 2 were the pupillary abnormalities and the mode of inheritance of the syndrome, the latter factor being unknown in case 1 The inability of the pupils to respond to any type of physical or chemical stimuli was thought to be due to defective innervation, though the site of this abnormality of the nervous system could not be determined in absence of other neurologic signs or symptoms This anomaly appears to be one of the rare examples of abnormalities of the nervous system that accompany the complete anhidrotic syndrome

In case 2 all of the patient's manifestations of anomaly were said to be duplicated in his only sibling, a sister, 8 months old When one remembers that the children's parents had common great-grandparents each of which may have carried the anomaly as a recessive genetic character, it is easy to understand why marriage between their descendants resulted in defective children These are obviously homozygous for the causative gene, and this recessive gene was concealed

urticaria is an allergic manifestation, the exciting cause of which is associated with home sleeping arrangements and can be controlled by detaining the child in the hospital for the night only Kinnear [8] described 14 cases of papular urticaria in children which began on their arrival in England from America and said that other cases occurred in their families He had also observed that same occurrence in newly arrived medical students He agreed with Hallam [6] that this condition had something to do with home sleeping conditions He had no idea of the cause and made no mention of the possibility of flea or other insect bites Tate [7] said, "The exciting agent is something connected with the patient's home environment"

My associate, Dr H J Templeton,[11] personally observed many cases of "papular urticaria" in Vienna He reported that patients with so-called papular urticaria suffered from typical flea bites and that their lesions would have been so diagnosed by any of the West Coast dermatologists He observed this "papular urticaria" developed in members of his own family and also in persons in the families of other American physicians and that the lesions were typical flea bites That the diagnosis was not shared by all Viennese dermatologists is evidenced by Dietrich's [12] discussion in which he stated that the cases were really examples of insect bites It is my belief that this confusion occurs in many cases in the literature

Urbach [13] devoted eight pages to the idea that most cases of papular urticaria are of allergic, endogenous or gastrointestinal origin and only two lines to cases in which insects were the cause His photographs 347 and 353 [13] are highly suggestive of bites In another text [9] he showed a photograph of papular urticaria which looks to me like insect bites Macleod's text [14] has a photograph which is almost certainly one of flea bites, with the puncta, papules, grouping and location A photograph in Andrews' text [15] needs to be differentiated from one of flea bites At a clinical meeting of the American Dermatological Association [16] a 3 year old child was presented from Canada as having an example of papular urticaria In the discussion Ayres and Weiss diagnosed the

until the consanguineous marriage by a dominant normal gene, that was absent in these two children Progeny of heterozygous parents would be expected to show a 1 3 ratio of defective to normal children, but this ratio often becomes apparent only in large families or in long family pedigrees

In case 3 a sex-linked recessive gene was responsible for the defect, according to the father of the patient, since only one male of each generation was affected In contrast, in case 4 we were unable to trace the anomaly at all One must conclude that the condition in this case represents a mutation, and the patient's progeny should be followed with interest to note the genetic transmission of the defect

The facies of the 2 adult anhidrotic patients (cases 3 and 4) is characteristic of the entire group Although in case 3 the patient did not have a saddle nose such as that described in case 4 and frequently described in the literature, the root of his nasal bridge was sharply depressed Both patients presented decided hypotrichosis, complete anhidrosis and hypodontia or anodontia to complete the full anhidrotic syndrome

The anhidrotic syndrome had limited the heat regulation in case 3 to such an extent that the patient's employment as a lifeguard was one of the few types of work which he could carry on in the summertime In case 4 the patient's activity was voluntarily restricted, but he was able to continue farm work in a northern state during almost the entire year We were unable to relate the cause of his periods of weakness and unconsciousness directly to increase in body temperature, but it was felt that a subthreshold cerebral dysrhythmia was made manifest either by the rise in temperature or by the hyperventilation or by both factors

These patients (cases 1, 3 and 4) were all of interest from the standpoint of histopathologic study In none of their biopsy specimens were we able to find sweat glands or sebaceous glands In case 3 the apocrine glands were also absent from the axillary skin examined This is in contrast to the reports of Sunderman,[11] whose patients had apocrine glands but no eccrine glands, as shown by microscopic examination The apocrine glands develop from anlages of hair follicles instead of directly from the epidermis as do sweat glands, in the embryo, and do not become active until near puberty The presence of highly developed apocrine glands and the sparse growth of hair, on one hand, and the absence of sweat glands, on the other, illustrate the complete suppression of the sweat gland formation and the incomplete suppression of pilosebaceous structures which are peculiarly characteristic of the anhidrotic syndrome

case as one of insect bites In the *British Journal of Dermatology and Syphilis* [17] a reviewer wrote of "papular urticaria (a condition furtively believed by not a few since Jonathan Hutchinson to be produced by insect bites) " Jonathan Hutchinson [18] expressed the opinion that fleas had something to do with the lesions "It may be that flea bites acting on a skin sensitized by faulty alimentary metabolism is the determining cause" Concerning the first step in treatment MacKenna [19] said, "Inquire judiciously into the possibility of infestation with fleas"

From all this evidence, I conclude that elsewhere in the world there is the same problem of differentiating papular urticaria from flea bites that exists on the West Coast

Fig 5—Histologic aspects of the flea bite Note the intensity of the reaction

PATHOLOGIC ASPECTS

A flea bite papule was excised from each of 5 patients for microscopic examination Each of these lesions was of the papular urticarial variety most commonly seen as the result of flea bites None was of the rarer bullous variety

In none of the excised specimens was there any significant change in the epidermis Most of the abnormal observations were in the subpapillary and deeper portions of the corium (fig 5) These consisted

SUMMARY

The clinical characteristics of hereditary anhidrotic ectodermal dysplasia are described, emphasis being placed on the diagnostic triad of symptoms anhidrosis, hypodontia and hypotrichosis The most important dermatopathologic abnormality, complete or almost complete lack of formation of sweat glands, is pointed out, along with its effect on the patient's heat-regulating mechanism The several modes of hereditary transmission of the syndrome, as well as the embryologic development of the anomalies, are discussed The essential similarities and differences between the anhidrotic syndrome and hidrotic ectodermal dysplasia, Werner's syndrome, Rothmund's syndrome and the Hutchinson-Guilford type of progeria are pointed out in tabular form Four patients who were affected by the anhidrotic syndrome, 2 of them infants, are reported on in detail The report includes physiologic investigations of sweating, histopathologic examinations of epidermal tissue and inquiries regarding the genetic transmission of the anhidrotic syndrome in each patient's family group There is need that the syndrome be recognized promptly, particularly in an infant, so that the child may not be exposed to a warm environment and, as his development progresses, may have the benefit of dental prostheses early enough to prevent some of the facial abnormality which results from uncorrected hypodontia or anodontia

in a lymphocytic infiltration around the blood vessels, which were dilated and often filled with the lymphocytes The same lymphocytic infiltration occurred around the sweat and sebaceous glands and, in 1 case, around the muscle fibers In three of the specimens there was a very pronounced lymphocytic infiltrate around the sweat glands deep in the corium and even as deep as into the fat layer (fig 6) I was impressed by the intensity of this deep lymphocytic reaction

DATA OBTAINED FROM OUR LETTERS OF INQUIRY

In the fall of 1947 my associates and I mailed letters to all certified dermatologists in the United States, Canada, Hawaii and Cuba, asking about the flea problem in their communities

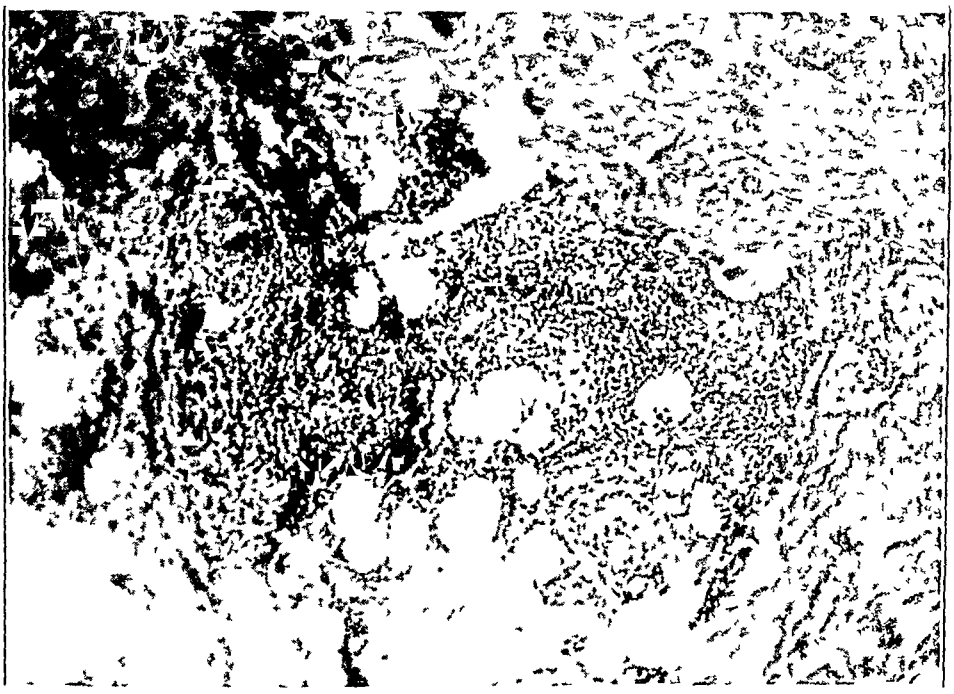

Fig 6—Histologic changes seen in the flea bite Note the intensity and the depth of involvement in the fat layer

The data in the letters received showed that fleas are a major dermatologic problem only in California Of the several hundred answers from all other parts of the country only a few persons gave as their opinion that fleas were a major medical problem in their community A slightly larger, but still small, percentage of letters stated that fleas were a minor problem In two states, Nevada and Colorado, some observers denied that cat and dog fleas even existed there

In California, however, in all letters from the San Francisco Bay area there was agreement that a real problem exists In eight letters from Los Angeles four dermatologists stated that the problem exists and four denied it All six letters from the Los Angeles suburbs contained statements that a moderate problem exists From the San Diego

FLEA PROBLEM IN CALIFORNIA

C J LUNSFORD, M D
OAKLAND, CALIF

THE TESTIMONY of present day dermatologists is that fleas are more of a nuisance in California, particularly in the San Francisco Bay area, than elsewhere in the United States

HISTORICAL ACCOUNTS

In the vast literature relating to exploration, settlement and life in California the references to misery caused by fleas encountered by the authors are related entirely to experiences in Northern California

Padre Juan Crespi,[1] the diarist of the Portola expedition of 1769, wrote that when the expedition visited an Indian village on Purisima Creek in San Mateo County they found the grass huts so infested with fleas that they called it "Village of the Fleas"

In 1786 the Frenchman La Perouse [1] had this to say about the fleas in Carmel and Monterey "Under the influence of the Missionaries the Indians had refused to make the slightest change in the construction of their huts because they could set fire to their huts when the fleas became a pest and could rebuild them in two hours"

Another Frenchman, Duhart-Lilly (1827-1828) [1] visited a ranch in the San Bruno Valley Concerning the sleeping arrangements he wrote, "We were compelled to stow ourselves away, guests, husband, wife and children all together, upon a great feather bed, where devoured by fleas we passed quite an uncomfortable night"

In the period of transition from Mexican sovereignty to that of the United States, the American Edwin Bryant, in his outstanding book, "What I saw in California," [1] wrote bitterly and in detail of the infestation of the rancheros and old missions with fleas He spoke of the missions as "nurseries of fleas" "If any sinning soul ever suffered the punishment of purgatory these torments were endured by myself last night," he said After a sleepless night there was no square inch of his body that was free from flea bites

Read at the Sixty-Eighth Annual Meeting of the American Dermatological Association, Inc, San Diego, Calif, April 28, 1948

1 The Flea in California History and Literature, California Hist Soc Quart **15** 329 (Dec) 1936

area 80 per cent of the letters had claims that fleas are a real problem Writers from Pasadena, Santa Barbara, Fresno and San Jose disclaimed that there is a flea problem in their localities

The writers described about the same varieties of eruptions as I have described A few specifically mentioned papular urticaria in children

Flea Antigen The great majority of the men stated they had had no experience with the use of flea antigen Most of those who had used it were from California, and their opinions varied from those of its being worthless to others that it was satisfactory in 70 to 80 per cent of cases treated Several men observed that the results were highly successful in some cases and that treatment completely failed in others

Results Reported from the Use of Locally Applied Repellents—The best results reported from the use of locally applied repellents and insecticides were obtained by those persons who used 0 5 to 10 per cent DDT (2,2-bis[*p*-chlorophenyl] 1,1,1-trichloroethane) Many military observers felt that Army 612 (2-ethyl-hexanediol-1,3) is, on the whole satisfactory Others reported varying results from the use of pyrethrum, rotenone and sulfur powder

Reports on the Use of Thiamine Hydrochloride Many of the men had used thiamine hydrochloride given by mouth as a repellent with varied results Eder [20] reported good results in both prevention and treatment Two reports from San Francisco had observations that thiamine hydrochloride administered internally was a 100 per cent effective repellent of fleas in human beings, cats and dogs According to others, it was of questionable value or completely worthless

Selectivity of Fleas Several of the men called attention to the selectivity of the action of fleas That is, very often in a family fleas will bite one member and not another, children being the most frequent victims Those in our office agree that this observation is an accurate one

Some of the men were attacked by human fleas but not by fleas from their own dogs Several observers were attacked by fleas in one geographic location but not in another For instance, fleas in their place of residence in San Francisco did not annoy them, but when they visited Los Angeles or some foreign city, such as Mexico City or Vienna, they would be severely bitten, the reaction in these cases being described as a severe bullous eruption

Some of the men thought that such things as body odor and sex hormones should be considered as accounting for the age and sex selectivity

20 Eder, H L Flea Bites Prevention and Treatment with Thiamin Chloride, Arch Pediat **62** 300 (July) 1945

The Rev Walter Calton (1850), in his book "Three Years in California,"[2] described the continued annoyance caused by fleas to strangers and observed that the native was not troubled by them

Carl Meyer (1855), under the title "Nach dem Sacramento,"[1] described a night spent on a ranch near Salinas He labeled his experience "flea fever"

> Hardly has one gone to bed when a band of these small devilish fleas pursue their bloody maneuvers on one's sensitive skin, driving away sleep and tormenting a man to madness One breaks out in a torturing sweat, and because of the frequent throwing off of the covers one runs a risk of contracting a fever

He mentioned that even in mixed company the subject of fleas was often the topic of conversation and that the gesture of scratching was not frowned on

Ernest de Massey wrote in his "Frenchman in the Gold Rush"[1] of his experiences in San Francisco

> There were millions of fleas in the sand near my shack On the floor was a layer of sand, the camping ground of a colony of fleas, which hopped around looking for a chance to make a good meal off me [and] by the time I was ready to retire my legs were literally covered with these blood thirsty insects

Frank Marryat, an Englishman, in his "Mountains and Molehills"[1] described his experiences in Santa Rosa, Calif On being shown his quarters he was "immediately attacked by the fleas with a vigor which was perfectly astonishing" He had been a wide traveler and had "been tortured by sand fleas in the Eastern Archipelago and by all kinds of mosquitoes from Malta to Acapulco," including the "famous 'tiger' breed against which there is no recourse but flight" "But," he said, "I would have preferred any of those annoyances to the attack of those Santa Rosa fleas" "The place was alive with them and they, raised in the rough school of the wild bullocks' hide, boldly faced as they attacked us" He stated that, on his mentioning the fact, his host predicted that he would get used to the fleas that he [the host] and his family never gave them a thought Thus the early settlers in California had observed that one became immunized against the effect of flea bites by being bitten by the fleas

In the San Francisco *Argonaut* of Dec 8, 1878,[1] there appeared a humorous article with the title "The Flea A Short Discourse on a Lively Subject" The author gave an account of his experiences with fleas encountered near what is now Redwood City At that time it was believed that fleas lived in the soil The author chose a site for his

COMMENTS AND STUDIES ON IMMUNOLOGY

The entomologists say that the old idea of host specificity is erroneous Persons who think they are not bitten by fleas from their own dogs actually may have been bitten until they have established an immunity Also, some persons not bothered by fleas at home may be sensitive to a slight variation in antigen from fleas in a strange city

It appears that as a person continues to be bitten he undergoes a natural desensitization to the antigen deposited by the flea This takes place gradually over a period of about a year There are people, however, in whom this desensitization occurs more slowly, and in some cases it never occurs Patients have been known to leave the Bay region permanently because the fleas have made their lives intolerable

The biologic explanation for the phenomenon of natural desensitization against insects is illustrated by an experiment done by Kenneth Mellanby [21] To study the varying reactions to insect bites in man he fed the yellow fever mosquito on Englishmen who had never been away from the British Isles The first bites produced an erythema about 1 to 2 mm in diameter and in twenty-four to forty-eight hours a delayed reaction consisting of an intensely pruritic urticaria-like papule 1 cm in diameter surrounded by a 2 to 3 cm zone of redness After the subjects had been bitten for a month the immediate reaction was an itching wheal which was followed by the delayed reaction in twenty-four to forty-eight hours The later reaction recurred each three to four days As the experiment continued the delayed reaction gradually disappeared and there was less itching, but the immediate reaction never failed to appear Dr Mellanby stated, however, that many Englishmen bitten by thousands of indigenous mosquitoes finally lost the immediate reaction and had complete desensitization He expressed the opinion that the two reactions were quite distinct and were caused by different antigens in the saliva of the mosquito

My associates and I believe our clinical observations tend to show that a similar process of desensitization occurs naturally on prolonged exposure to flea bites

In 1939 Cherney, Wheeler and Reed [22] tested two groups of persons to an antigen made from dog, cat and human fleas indigenous to San Francisco About 85 per cent of the immune group gave no reactions A number of susceptible persons were given weekly injections for six weeks with the flea antigen in an attempt at desensitization The results of treatment were fair

22 Cherney, L S , Wheeler, C M , and Reed, A C Flea-Antigen in Prevention of Flea Bites, Am J Trop Med **19** 327 (July) 1939

home near a ranch called "Rancho de las Pulgas," where the beauty of the country impressed him He observed that potatoes planted in the soil had to be removed with a crowbar because of the hardness of the soil and that the potatoes when dug were as "flat as pancakes" He thought that fleas could not live in such soil On calling on the owner of the ranch he noticed a stick ladder leading from the floor to a high attic under the roof, where the household slept The significance of such an arrangement became apparent when, on being severely bitten about his ankles, he looked down and saw that his white socks were covered with "pepper in motion" The home owner then told him that his routine for sleep was to remove all his clothes, leave them on the floor and scurry up the ladder, leaving only the clothes for food for the fleas Subsequently the author learned that "Rancho de las Pulgas" signified "The Farm of the Fleas"

ENTOMOLOGY OF FLEAS [3]

The three species of fleas most commonly attacking man in the United States are the human flea (Pulex irritans), the cat flea (Ctenocephalides felis) and the dog flea (Ctenocephalides canis) In the eastern part of the United States the dog flea is the dominant pest In the South and West the human flea is In California the human flea and the cat flea are equally dominant (fig 1)

The eggs of all these species hatch in the nests or resting places of their hosts, rarely on their bodies, or else in dust or organic debris in buildings Following the life cycle of any insect, from egg to larva to pupa within the cocoon, the adult flea emerges in about two weeks Newly emerged adults are usually very fat and can live for several months, under favorable conditions, without feeding The female flea must have a blood meal before her eggs can be fertilized Most fleas visit the body of the host for relatively short periods for the purpose of obtaining a blood meal

On smooth surfaces, fleas progress by means of short jumps They may sham death when disturbed They usually leave a dead host as soon as the body becomes cold They like warmth and moisture but shun daylight It has been determined that some adult fleas can jump vertically nearly 8 inches (20 cm) and horizontally 13 inches (33 cm) Fleas prefer hosts with nests

The life cycles of fleas are decidedly influenced by meteorologic factors Low atmospheric humidities in particular are inimical to them

3 The data and some of the phrasing on entomology were given to me by Morris A Stewart, Ph D , Professor of Parasitology, the Division of Entomology and Parasitology, University of California, Berkeley, Calif

In 1941 McIvor and Cherney [23] treated persons sensitive to flea bites by injecting into them an antigen extracted from whole San Francisco fleas They reported encouraging results

On the basis of data shown in McIvor and Cherney's article the Lilly Research Laboratory prepared an antigen according to the methods developed by the authors but obtained dog, cat and human fleas from Bolivia and Mexico City This extract has been used in our office since it was first manufactured in the treatment of children who were most persistently susceptible to flea bites The results obtained were not controlled and were difficult to evaluate properly because we could not determine whether the "cure" was the result of the injections or was an expression of a natural immunity developed from the patient's being constantly bitten by fleas

Hatoff,[24] using Lilly's commercial antigen and a technic similar to that used by McIvor and Cherney,[23] reported successful desensitization in about four fifths (80 per cent) of children treated

We feel that studies should be made to determine whether or not there is a difference in the antigen injected by fleas of different kinds and from different localities and, if so, of what clinical importance it is

EXPERIMENTS WITH FLEA ANTIGEN

With the cooperation of Drs Bernard H Winston of Kansas City, Mo, and Knox Freytag at the Presidio in San Francisco, together with the residents at Highland–Alameda County Hospital in Oakland, 45 children and 104 adults were tested with the Lilly flea antigen, the tuberculin technic being used Results are so lacking in uniformity that no conclusions can be drawn Therefore, we wish to reserve our findings until they have been rechecked

STUDY OF REACTIONS TO FLEA BITES

It is difficult for one to obtain fleas because of the present day universal use and efficiency of DDT as an exterminator The fleas we have used have been cat fleas, obtained from dogs [25] These fleas were fed on the forearms of volunteers The hungry fleas fed without hesitation When the fleas were satisfied they became active We usually used six to twelve fleas on each subject At times we could get only three or four The fleas will feed three or four times a day and can be kept alive in the test tube with such feedings on the average of only ten to fourteen days

23 McIvor, B C, and Cherney, L S Studies in Insect Bite Desensitization, Am J Trop Med **21** 493 (May) 1941

24 Hatoff, A Desensitization to Insect Bites, J A M A **130** 850 (March 30) 1946

25 The fleas used in our experiments were furnished through the courtesy of Morris A Stewart, Ph D

The length of time required for each developmental stage is very largely determined by the prevailing temperature and humidity Adult fleas may remain alive for more than five years if the environmental conditions are favorable, such extremely long adult life is, of course, very exceptional, usually the flea lives only a few weeks or months Because of the lack of extremes in temperature and the relatively high humidity, in coastal California fleas breed the year around They are found in homes where cats and dogs are kept as pets, particularly in the carpets and cracks of floors and corners of rooms They are found in basements where the animals sleep at night They are particularly apt to be found in large numbers in such basements from which the usual animal

Fig 1—Cat flea (Courtesy of Morris A Stewart, Ph D, Department of Entomology, University of California, Berkeley, Calif)

and human tenants have been absent for a period I know of persons who have walked into their own basements after a summer vacation, to have their white trousers literally covered with very hungry fleas in a few seconds Fleas also frequent outhouses, sand piles and lawns and such places as theaters I know of people who are bitten by fleas whenever they attend any theater

CLINICAL PICTURE

The typical clinical picture of reaction to flea bites is a grouped, itching, urticarial, papular eruption, some papules of which contain a central red punctum (fig 2) These lesions are most often found along the

EXPERIMENTS

With Normal Conditions—EXPERIMENT 1 The fleas were fed on 12 members of our office staff and their families All except 1 were old residents of the Bay region The exception had been reared on a ranch and knew that she had been exposed to fleas all her life Although the fleas fed with equal avidity on all 12 subjects, only 2 persons showed a positive reaction Both of these had been flea-sensitive all their lives The reactions were both immediate and delayed This experiment demonstrates the immunity of 10 out of 12 old time Californians to flea bites

EXPERIMENT 2—Fleas were fed on 8 volunteer students at the University of California in Berkeley, none of whom gave a history of previous sensitivity to fleas Of the 7 that returned for observation only 1 had been a resident of the San Francisco Bay region for longer than two months The exception had lived here for six months Seven of the 8 volunteers showed a positive delayed reaction at the end of forty-eight hours This experiment indicates the sensitivity of recent residents in the Bay region to flea bites

EXPERIMENT 3—Fleas were fed on 4 bottle-fed newborn babies at the Highland-Alameda County Hospital None of the babies had been out of the hospital At the end of forty-eight hours there had been no reaction This experiment indicates that persons on first being bitten by fleas are not sensitive to their bites

With Local Application of Repellents—Oil of Citronella Two of our nurses applied oil of citronella to their forearms The fleas were repelled and did not feed It was interesting to see them dance all over the feeding ground

Pyrethrum Two subjects had powder containing 0 7 per cent pyrethrum dusted on their forearms In 1 case the fleas fed In the other the fleas were repelled after five minutes of feeding In both instances fleas were listless for twenty-four hours and would not feed but recovered In 2 other subjects other fleas were exposed to a heavier powder sprinkling Although we did not see them feed, they all died in twenty-four hours

Army 612 (2-ethyl-hexanediol-1, 3) Three subjects were tested The fleas were repelled, and most died within twenty-four hours

DDT Powder (7 5 per cent DDT) Two subjects were studied The fleas would not feed after five minutes and died in four hours We did not pursue this experiment because we could not afford to kill more of the fleas

Camphor Spirits of camphor was applied to the forearms of 6 subjects, and fleas were placed thereon The fleas would not feed One volunteer forgot to cleanse the camphor from his forearm properly Four hours later two tubes of fleas were fed on the same site The fleas were dead in fifteen minutes

Petrolatum In four instances fleas would not feed through petrolatum rubbed on the forearm

With Internally Administered Repellents—Sulfur Four patients were fed calcium sulfide, ¼ gram (15 mg) twice a day for seven days Fleas fed normally and were not made ill We have been advised that farmers in certain parts of the country, believing that sulfur will protect them from fleas, take it in the spring for that purpose

Quinine Eight tubes of fleas were fed on 4 subjects given 5 grains (0 30 Gm) of quinine sulfate three times a day for three days At the end of thirty-six hours 90 per cent of the fleas were dead

Thiamine Hydrochloride One subject was given 100 mg of thiamine hydrochloride, intramuscularly One half hour later the fleas fed Six hours, ten hours

waist line and on the hips and shoulder area, where the clothing fits snugly (fig 3) They may, however, be on any part of the body Grouping is one of the most characteristic features The flea is not content to bite in one area and remain attached at that point until its hunger is satisfied Rather, it moves along, biting in an irregular but grouped

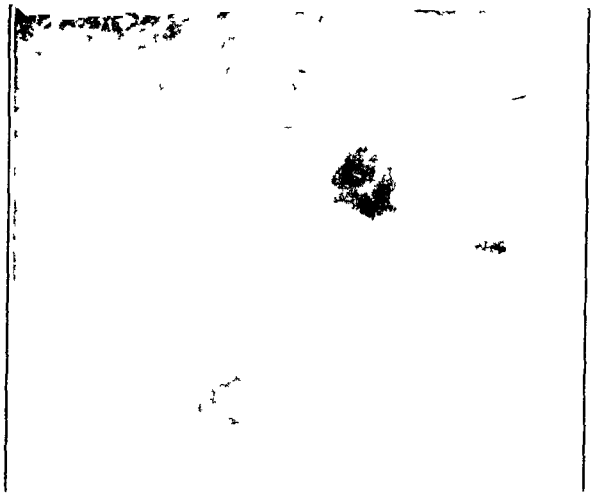

Fig 2—Individual flea bites, showing papules, central puncta and vesiculation

Fig 3—Flea bites in typical round the waist distribution (Courtesy of Rees B Rees, M D, San Francisco)

pattern In addition, there may be more scattered or satellite lesions present In some cases a generalized papular urticaria is seen (fig 4) It is believed that many of such papules are allergic reactions to one or a few bites and are an expression of sensitivity to the antigen injected

and twenty-two hours later, fleas were repelled and would not feed on either the subject or 4 other subjects who had not taken thiamine hydrochloride Two days later the fleas fed on the original subject

Four subjects were given 100 mg of the drug intramuscularly at 11 a m, 4 30 p m and 10 30 a m the next day At 1 p m fleas were planted on all subjects and fed for five minutes, and then they quit feeding At 8 a m, 9 a m and 3 p m the next day the fleas would not feed At 8 30 a m the third day most of the fleas were dead The fleas that remained alive fed

Seven test tubes of fleas were fed on 3 subjects given 100 mg of thiamine hydrochloride by mouth, three times a day At the end of six hours the fleas fed reluctantly At subsequent plantings they fed for only five minutes and were inactive At the end of three days most of them were dead

This experiment indicates that at first fleas are repelled but later feed and die when they are planted on patients given thiamine hydrochloride

Fleas were fed on 4 persons with a history of sensitivity to fleas There developed a typical flea bite reaction After the subjects had taken three doses of 100 mg of thiamine hydrochloride, the fleas were again fed on them The subsequent effect was either a less severe reaction or none at all

The question arises as to whether this lowered reactivity was due to the desensitizing or to the repellent action of thiamine hydrochloride

CONTROL OF FLEAS

The most practical method of controlling the flea problem is by means of the newer insecticides, such as DDT If this substance is sprayed onto carpets, floors, overstuffed chairs and basements the fleas will be quickly destroyed It is not necessary for one to apply it to dogs and cats to rid them of fleas Instead it should be sprayed into their kennels or nests or onto their favorite sleeping places One such spraying every two months will keep animals free from fleas

CONCLUSIONS

Flea bites constitute an annoying problem in coastal California, particularly to newcomers in the San Francisco Bay area

My associates' and my experiment of feeding fleas on newborn infants confirms our clinical observations that persons first have to be bitten by fleas in order to become sensitive Our experiments of feeding fleas on old time Californians and on newcomers confirm our clinical findings that most people become immune after having been bitten over long periods

We are certain that most cases of "papular urticaria" in California are, in reality, due to flea bites and suspect that this is probably true elsewhere

Further studies and better antigens are needed for the investigation of the value of artificial desensitization

Oil of citronella, pyrethrum, Army 612, DDT, petrolatum and camphor applied locally are of value as repellents

her closely but could get no history of the ingestion of arsenic I simply think that we have to decide whether this entire picture should be included in a single dermatologic entity, which I rather doubt at present

DR HAMILTON MONTGOMERY, Rochester, Minn I thought this was a case of congenital defect She has a flat nose You could not call it a congenital ectodermal defect with the changes in the tongue, but we have seen cases of endodermal and ectodermal changes merging together She did not have changes in the teeth but had changes in the palms that might indicate an ectodermal defect, as would the changes in the neck In addition she has apparently had a dermatitis which does not belong with that picture I would suggest that her family history be investigated

DR FRANCIS W LYNCH, St Paul, Minn I thought of the possibility of an ectodermal defect, but the mucosal changes were too great The family history is normal as far as could be learned on brief questioning

Eczema Vaccinatum Presented by DR F E SENEAR and staff

A Case for Diagnosis (Secondary Vaccinia [Autoinoculation]) Presented by DR F E SENEAR and staff

The continued taking of quinine by mouth or of thiamine hydrochloride by mouth or injection is of clinical and experimental value in the repelling of fleas

Modern insecticides, such as DDT, applied to the known breeding places of fleas offer the most practical solution of the problem

3115 Webster Street (9)

ABSTRACT OF DISCUSSION

DR LESLIE M SMITH, El Paso, Texas I spent the summer of 1925 in the clinic of Dr Harry Alderson at Stanford, and I have had both clinical and personal experience with the hardy California fleas I have seen reactions to their bite so severe and extensive as to suggest erythema multiforme or urticaria That allergy to the toxins injected by fleas and other insects occurs in some persons there can be little doubt This is evidenced by the extreme local reactions which occur in some victims and, I believe, by the appearance of some urticarial lesions which do not occur at the sites of bites, or at least do not contain the puncta of typical bites

In the El Paso area, on account of the very low humidity, fleas are no problem There are mites, bedbugs, mosquitoes and some other insects, and manifestations of allergy are occasionally observed following the bites of some of these In addition to typical bites one occasionally sees scattered urticaria papules, which do not appear to be the result of bites and presumably are an allergic response to absorption of toxin from the bitten areas

I am not prepared to state that in patients encountered in my practice insect bites are the principal cause of lichen-urticatus-like eruptions, but I think it is quite probable that I have not been sufficiently alert to the possibility of this factor in such cases It is a common observation that most cases of lichen urticatus and prurigo occur among the type of patients in whom malnutrition is common These same patients usually live under conditions which favor the presence of insects and the possibility of insect bites I, for one, shall be more conscious hereafter of the possible role of insects in the lichenoid and urticarial papular eruptions

I have had no experience with treatment by desensitization to insect toxins, but the fact that a person may gain tolerance after being repeatedly bitten would seem to indicate that tolerance might be produced artificially by hypodermic injections of the proper antigen I believe this line of reasoning is worthy of further work

In areas where fleas constitute such a problem as they do in California, it is probably wise to give orally or parenterally administered repellents, such as quinine or thiamine, to susceptible persons, but where fleas and other insects are not so numerous I believe the intelligent use of repellent sprays about their breeding places and about the patient's environment will be sufficient for their control

I should like to know what success Dr Lunsford has had with use of the antihistaminic drugs in the control of reactions to insect bites

DR PAUL E BECHET, Elizabeth, N J Dr Lunsford's paper is of interest, in view of the fact that plague-infected fleas (Xenopsylla cheopis) caused the unprecedented death of over 60,000,000 persons from the year 1348 to the end of the Seventeenth Century Another killer of men, typhus, can be carried by fleas as well as by lice, which observation calls attention to the fact that Hieronymus Fracastorius, the author of "Syphilis sive Morbus Gallicus" published "Contagion,

lusterless, pierced the crusts and scutula There was an offensive "mouse" odor to the scalp There were numerous areas of atrophic scarring with alopecia Examination by means of the Wood filter revealed a dull gray fluorescence of about 60 per cent of the hairs of the scalp Of interest was the fact that the involved hairs were fluorescent throughout their length Several of these hairs were pulled for microscopic examination The hairs pulled with some difficulty, though with no pain to the patient Exerting tension on the hair gave one the same impression as pulling a stiff rubber band, i e, the hairs were distinctly tensile

Two finger nails were involved slightly, the process beginning at the distal lateral portion of the nail Microscopic examination of the nail from these areas showed numerous myceliums

Microscopic examination of hairs treated with a 20 per cent solution of potassium hydroxide revealed large spores, many in long chains and others occurring individually In crusts clinging to hairs, hyphae were extremely numerous The spores were seen within the entire length of the hair shaft Also noted within the shaft were numerous air bubbles

A tentative diagnosis of favus was made, and material was sent to Dr E D DeLameter of the Mayo Clinic and to Mr David Mitzkus of the Mycology Laboratory at the Army Area Laboratory, Fort Sam Houston, Texas, for culture Both laboratories reported growth of Achorion schoenleini

The patient has refused roentgen epilation, and treatment has consisted of manual epilation, with the use of a General Electric Purple X® bulb for fluorescence and topical application of an ointment of 20 per cent zinc undecylenate with 5 per cent undecylenic acid (zincundecate [desenex®]) and other fungicidal preparations Most of the improvement noted is apparently due to the correction of the hygienic status of the scalp At this time the infection is still unchecked

A questionnaire was sent to several dermatologists throughout the state Dr Bedford Shelmire of Dallas stated that he had seen 2 cases of favus, which apparently were endemic, within the past twenty years Dr C F Lehmann and Dr J L Pipkin of San Antonio, reported that "the only cases of favus which we have seen were outside San Antonio" All others questioned stated that they had never seen a case of favus in Texas

CONGENITAL DERMOID INCLUSION CYST

Report of a Case

MAURICE J COSTELLO, M D
NEW YORK
WILLIAM F LOVEBURY, M D
COLUMBUS, OHIO
AND
JOHN F DALY, M D
NEW YORK

Dermoid cysts situated on the bridge of the nose are relatively rare, and while seen occasionally by otolaryngologists they have not been brought to the attention of dermatologists

This type of cyst belongs to the group of tumors found about the nose which, according to Luongo,[1] result from the trapping of a portion of the dermis by

1 Luongo, R A Dermoid Cyst of the Nasal Dorsum Arch Otolaryng **17** 755-759 (June) 1933

Contagious Diseases and Their Treatment" in 1546, and in his discussion of the etiology of typhus stated that it is caused by a "germinis" transmitted to man by the bite of an insect and not by direct contact or fomites This brilliant observation of Fracastor's four centuries ago was unfortunately completely ignored, had it been acted on and further investigated, it would have saved millions of lives

I hope I may be pardoned for bringing up the lethal importance of the flea, rather than its dermatologic significance, and also that Dr Lunsford may not suffer for his temerity by mentioning fleas and California in the same breath

DR N P ANDERSON, Los Angeles When I first came to California I mistakenly diagnosed flea bites as ordinary urticaria Occasionally the diagnosis of flea bites is made on the findings of bullous lesions the size of a walnut It is hard to conceive that such bullae can be the results of flea bites I think that Dr Lunsford, having access to so many fleas, could disprove the idea that a great many of these lesions are allergic It seems to me that this should be proved or disproved Take these fleas, isolate the person, and let one flea bite him to see whether lesions remote from the bite do occur I don't believe that these so-called remote lesions are allergic I have seen five hundred lesions on one member of my family At certain times of the year there is an epidemic of flea bites Such an epidemic is usually associated with hot spells Endemic cases are seen throughout the year I should also like to mention the transmission of disease by biting insects The bubonic plague first appeared in this country in the Chinese quarter of San Francisco early in the 1900's Oriental fleas carrying the transmittal agent of bubonic plague have been found as far east as Colorado This reservoir of plague extends over the nation and sometime in the future may burst forth into an epidemic

DR NORMAN EPSTEIN, San Francisco I had the pleasure of reading Dr Lunsford's paper at home, and I think he should be complimented on the well planned investigation which he has made Examination of the literature shows a lack of papers on this subject Those of us who practice dermatology in the San Francisco Bay area will concur in the conclusions which Dr Lunsford has drawn There may be some difference of opinion about certain points Dr Anderson has emphasized the role of the flea in transmitting diseases We are all familiar with that Some of us do not realize that bubonic plague, which is transmitted by the flea, still exists in this country There have been 506 cases of bubonic plague in America since 1900 There have been 300 reported from San Francisco, in 268 of which the patient died The last case was reported in 1942, but we cannot be assured that new cases will not develop when least expected Tularemia is spreading from California throughout the country and into Canada by way of fleas transmitted from one rodent to another I agree that a large majority of the cases of papular urticaria in San Francisco are very likely due to flea bites At times the eruption is so severe that some people have to move from San Francisco One of the most remarkable things about the flea is that it will not bite everyone This selectivity on the part of the parasite can hardly be explained on desensitization alone The work of Shannon in regard to thiamine hydrochloride in the repelling of mosquitoes may have a practical bearing in making certain parts of the world more habitable This work was done in 1933 Eder noted that fleas were repelled from children given thiamine hydrochloride Shannon expressed the belief that this action was due to a change in body odor of the person taking the thiamine hydrochloride Perhaps that is the explanation Usually one sees fleas on logs and flea bites on patients who work in warehouses on wooden floors The lesions are occasionally bullous

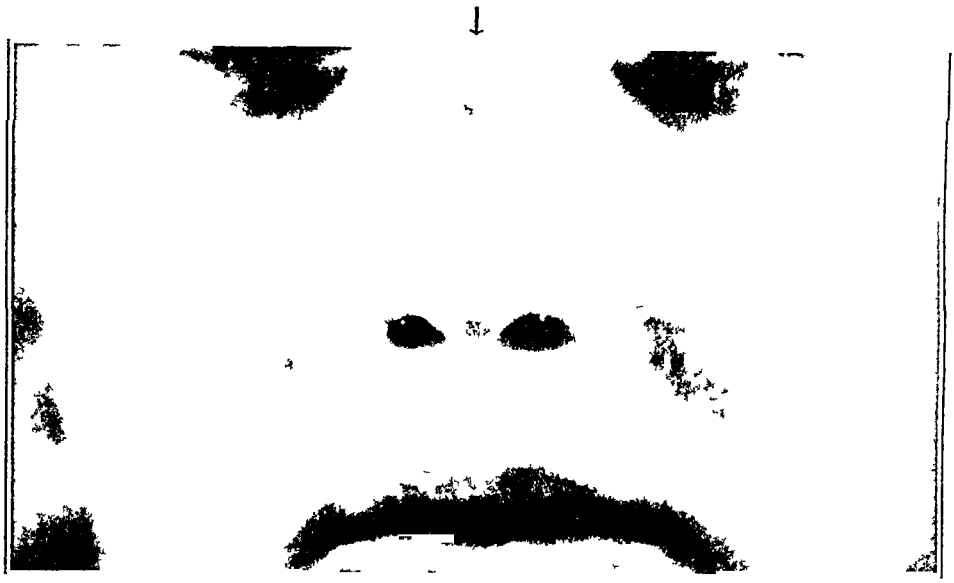

Fig 1—Congenital dermoid inclusion cyst of the nose, with protruding short, black hairs

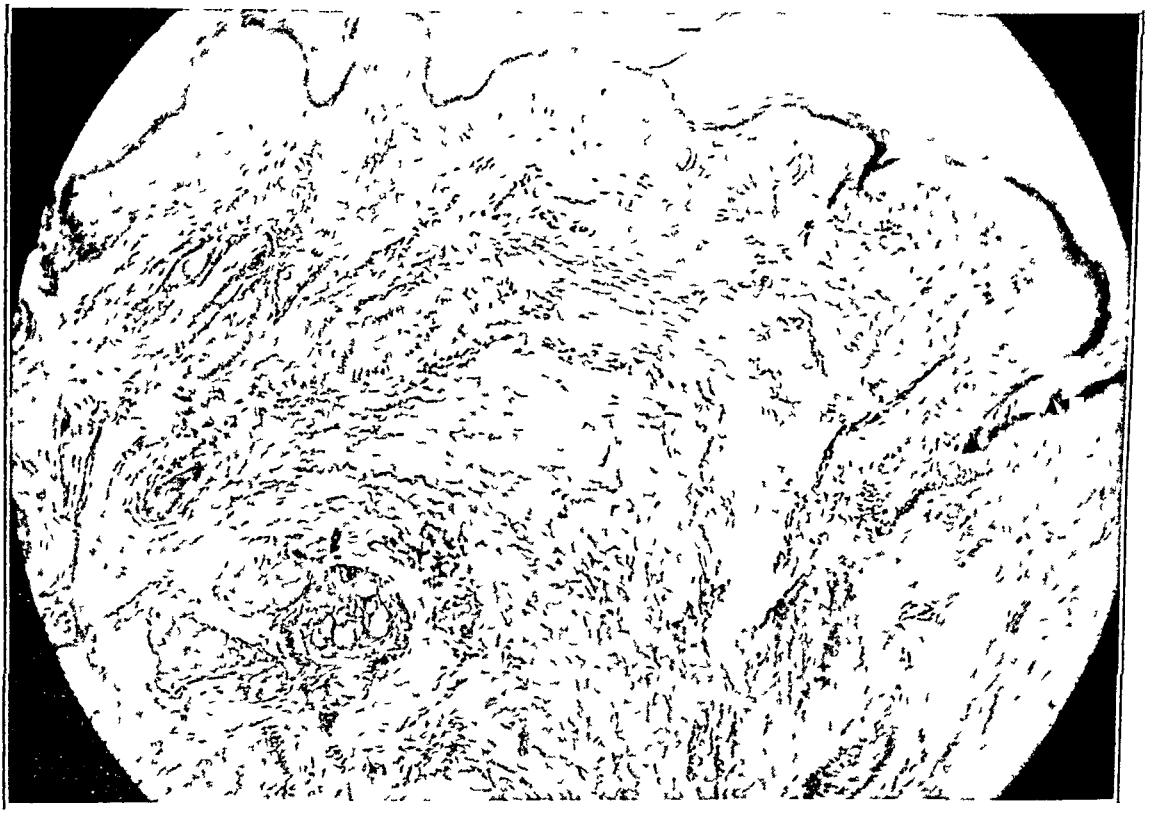

Fig 2—Partial view of the epidermis lining the floor of the cyst, low power magnification, hematoxylin and eosin stain

In our hands, the use of flea antigen has not been convincing in its effects My associates and I have been unable to say that flea antigen has accomplished very much clinically In our hands, the antihistaminic drugs have given some relief

DR. SAMUEL AYRES JR, Los Angeles With reference to humidity, it seems that in our part of the state the flea season is in the hot, dry months, beginning with July, August and September, when the humidity is low The definite instances of flea bites are more pronounced at this time The question of regional immunity is another interesting thing People reaching the Bay area become bitten, and I have also encountered long time residents of San Francisco who have been bitten by our variety of flea One can be immune to California fleas but not to Mexican fleas People may be bitten by cat and dog fleas in any part of the country I know of one person who has been susceptible to dog fleas and is unable to keep dogs Several years ago, in the literature, I ran across an account of an experiment in which a flea was put in the center of a round table and invariably hopped to one person regardless of his position at the table I have had some degree of success with the use of histamine azoprotein (hapamine®) desensitization for highly sensitive persons This drug did not stop the fleas from biting, but the reaction was much less severe An editorial in the *California Medicine* about eight months ago (Hartman, M M *Calif Med* **60** 242, 1947) mentioned the valuable effect of histamine azoprotein in treatment of insect bites Thiamine hydrochloride in a dose of 100 mg three times a day is of definite value in conferring temporary immunity

DR SAMUEL PECK, New York We have had relatively little experience with flea bites in New York city, but, if I may judge on analogy with the investigations which my associates and I carried out during the War ("Cutaneous Reaction Due to the Body Louse," *J A M A* **123** 821 [Nov 27] 1943), it is probable that the flea bite, like the louse bite, is an allergic reaction Pruritus became evident only after allergy was established

Interestingly enough, we could show that the feces as well as the bite of the louse played a role in the cutaneous eruptions which were produced

DR C F LEHMANN, San Antonio, Texas Since the question of allergy is brought up, I rise to testify that I have remained sensitized to the toxin of the flea bites since I was a small boy and was heavily infested with fleas while seeking shelter from a heavy rainstorm one night Ever since then, a flea bite will cause an urticarial reaction not only locally but also generally in me

The diagnosis of such bites sometimes presents quite a problem A child may be brought in with a line of papules with central puncta The flea has the propensity of crawling along a line and biting, and the line of papules is strong corroborative evidence of flea bites, despite the fact that the proud mother might not want to admit such things as fleas having bitten her child These lines of papules are sufficient evidence to substantiate the suspicion of the etiologic factor

DR H S ALDEN, Atlanta, Ga I don't believe that flea bites occur only in California We have them in Georgia In Georgia the "chigger flea" produces most of our troubles I should like to mention the fact that the Negro (the dark Negro, not the mulatto) is more or less immune to the bites of the chigger White men could not be worked in the swamps, but the Negroes could Once I tried to get some students to collect chiggers by laying a sheet or some white material on the ground The chiggers will come to that sheet in large quantities and can be collected I have therefore warned patients never to go into the woods with white shoes or white clothes

DR C J LUNSFORD, Oakland, Calif I thank all the discussers for their expressed interest in my paper

intrusion of the frontonasal plate between the embryonic nasal dermis and mucosa The bridge of the nose, exactly in the midline, is a common location

Most of these growths are discovered before the fifth year of age Secondary infection is common and is followed by sinus formation, with discharge of sebaceous material and pus Occasionally, as with the patient considered here, the presence of hairs calls attention to these congenital anomalies

REPORT OF CASE

A B, a white girl, was first seen by one of us (M J C) when she was 5 years old Her mother gave a history of noticing a small lesion on the bridge of the child's nose when she was 6 months old Since that time the growth had constantly had small black hairs and a thick discharge coming from the opening in the skin There was no family history of similar lesions or other congenital defects

Physical examination revealed a well nourished, well developed, white female child with no abnormalities except a small, match head–sized opening on the bridge of the nose at the junction of the cartilaginous and bony portions, exactly in the midline From this opening thirty to forty black hairs protruded The hairs were midway between lanugo and terminal adult hairs and could be removed easily with moderate traction On gentle pressure a thick, sebaceous material could be expressed There was little pain and no inflammatory reaction around the opening of the sinus

Treatment, which was carried out by Dr John F Daly, consisted in injecting methylene blue into the cyst to facilitate determination of the exact extent of the lesion An elliptical incision was made around the opening of the sinus, and the growth was completely dissected out It was found to mushroom out under the skin and was about pea sized, extending down to the junction of the cartilage and bone of the nose, but it did not involve either Grossly, the lining of the cyst looked like the skin of the scalp or bearded region

Histopathologic examination of the lining of the cyst revealed a normal-appearing epidermis except for a number of vacuolated cells in the basal layer The dermis contained no abnormal cellular elements but did show a large number of hair follicles with their associated sebaceous glands There was no evidence of sweat glands, a finding which has been consistent in previously reported cases

COMMENT

Congenital dermoid inclusion cysts of the bridge of the nose frequently extend down into the nasal septum and necessitate extensive surgery Other methods of therapy, such as electrolysis or destruction with high frequency current or cautery, often result in inadequate removal, recurrences and poor cosmetic results On one occasion, we saw a lesion such as the one described treated as a sebaceous cyst by electrosurgery with a final result of the development of a basal cell epithelioma

SUMMARY

A case of congenital dermoid inclusion cyst of the nasal dorsum is presented An excellent cosmetic result, with no recurrences of the growth, followed treatment

140 East Fifty-Fourth Street (22)

In answer to Dr Leslie Smith's question I have not had sufficient experience with the use of the antihistaminic drugs in the control of reactions to flea bites to permit me to discuss the subject

In answer to Dr Bechet's question as to the part blood-sucking insects play in producing the "cutaneous ills of mankind," my observations have in the main been limited to the bites of fleas In those cases in which the allergic reactions are expressed as generalized urticarial or erythema-multiforme-like eruptions, I think there is no doubt but that a rise in temperature would be present

Dr Anderson's idea of planting fleas on persons suspected of being allergic to flea bites and thus demonstrating whether or not such lesions as bullous ones develop far from the sites of the bites is an interesting one My associates and I hope to be able to follow through on it

I was interested in Dr Peck's experiment, proving that in the case of the louse the antigen producing the cutaneous reaction was obtained from the feces as well as from the salivary glands of the louse The group from the Hooper Institute, who did the original work in preparation of the antigen used by Eli Lilly, ground up the whole fleas, including the contents of the intestinal tract, in the production of their antigen In the case of fleas, however, the clinical observation of inflammatory reaction developing about the central punctum would make it appear likely that the flea antigen is in their salivary glands

We were interested to learn that Drs Epstein, Ayres and Lehmann agreed with us that fleas can produce an allergic response

LICHEN-SCROFULOSORUM-LIKE LESIONS ASSOCIATED WITH SARCOIDOSIS

Report of a Case

MATTHEW J BRUNNER, M D
AND
MILTON ROBIN, M D
CHICAGO

Lichen scrofulosorum is characteristically associated with a high degree of sensitivity to tuberculin, patients in up to 67 per cent of cases showing positive reactions to old tuberculin in a dilution of 1 1,000,000 [1] The finding of apparently typical lesions of lichen scrofulosorum in a patient exhibiting negative reactions to intracutaneous injections of old tuberculin in dilutions as low as 1 10 is therefore unusual Microscopic examination of cutaneous biopsy specimens in this case revealed a histologic structure characteristic of sarcoid, and on further study laboratory and clinical observations of sarcoidosis involving the eye, salivary glands and lungs were made The association of lichen scrofulosorum with sarcoidosis has been noted on several occasions in cases cited in the transactions of dermatologic society meetings, but the observation of a sarcoidal histologic pattern in lesions of lichen scrofulosorum is apparently unique Mitchell and Nomlund,[2] Cannon,[3] Cornbleet,[4] Michelson [5] and Becker [6] have reported on the clinical concomitance of the two conditions Biopsy of the lichenoid lesions in Cornbleet's case was reported as revealing hematogenous tuberculosis In Cannon's case, the histologic appearance was that of lichen spinulosus

REPORT OF CASE

A mulatto woman, aged 26, was seen in the Department of Dermatology, Research and Educational Hospitals, in August 1946, complaining of joint pains, dryness of the mouth, swelling of the glands of the neck and a cutaneous eruption of three months' duration There had been slight loss of weight, fatigability and low grade fever during this period Examination on admission to the hospital revealed a slender woman, apparently not acutely ill, with an eruption on the neck, shoulders and back, consisting of grouped, acuminate, pinpoint-sized to millet seed–sized, skin-colored papules, some of which were pierced by short, horny spines A few of the patches had cleared centrally to produce annular lesions (figure) There were numerous areas, from the size of a dime to that of a quarter,

Clinical Notes

PAIN IN A BREAST DUE TO NEUROSYPHILIS

CARL F BAUMEISTER, M D
RIVERSIDE, ILL
VICTOR P SLEPIKAS, M D
BERWYN, ILL
AND
DUANE D DARLING, M D
CHICAGO

ANY NEW manifestation of syphilis is a matter of clinical interest The literature fails to reveal an authenticated instance of neurosyphilis as a cause of pain in a breast

REPORT OF A CASE

Mrs K D, aged 55, had pain in the right breast, increasing in amount for five years This pain would tend to come in waves of sudden onset, severe intensity and varying duration of one to thirty minutes and would terminate with a feeling of soreness The number of attacks in twenty-four hours would vary, but they were tending to occur almost continuously in the month prior to her hospitalization, which occurred in February 1947 When the patient had an attack and was not taking opiates she could obtain relief only by squeezing her breast violently Since this was not very effectual, codeine or other opiates were given four or five times daily, with partial relief

Since the pain was equally severe and bizarre, the patient had seen numerous physicians, and very complete work-ups, including many serologic tests, had been made Owing to the fact that she could not speak English well and tended to call her bouts "gas pains," her appendix had been removed in 1943 In April 1946, because the gallbladder was poorly visualized, it was removed, the pathologist reported mild fibrosis Neither of these procedures was of the slightest benefit as far as the main symptom was concerned The situation had reached the point that the patient wanted her breast removed

For the last two years she had been having increasing difficulty in vision, tending to have diplopia at times in the last year She had had three normal children, who were all living and well

There were only a few points of pertinent interest in the examination 1 The patient had paresis of the right sixth cranial nerve 2 The reaction to light was sluggish in both eyes but especially in the right 3 The breasts revealed no abnormality 4 Other neurologic findings were not significant

As the patient had had complete gastrointestinal and cardiopulmonary examinations, with roentgenograms and electrocardiograms proving noninformative, it was decided to see if we were not dealing with one of Head's zones of referred pain Accordingly, a lumbar puncture was done for the first time on this patient on Feb 8, 1947, there was no increase in pressure One specimen of spinal fluid examined in the hospital laboratory gave a negative result in the Kahn test, the globulin content was 2 plus, and the Lange colloidal gold curve was 5543221000 A portion of the same specimen sent to the state laboratory gave a positive reaction to the Kahn test, there was no report on globulin, and the colloidal gold curve was 1123322110 As usual, all the serologic tests showed negative results

A tentative diagnosis of neurosyphilis was made, and, starting on February 15, an injection of iodobismitol® (a solution of bismuth sodium iodide and sodium iodide in propylene glycol containing saligenin and acetic acid) was given twice weekly on eight occasions Within three weeks the patient noted a definite diminution of the pain in the breast A total of four injections, each of 2 Gm, of tryparsamide U S P, was given weekly, starting March 19 This therapy was discontinued because, though there was almost complete disappearance of the pain, the vision became much poorer The patient had another course of injections of iodobismitol,® followed by four weekly injections of 45 mg of dichlorophenarsine hydrochloride U S P On June 18 spinal fluid obtained by lumbar puncture revealed 3 plus globulin and gave a negative result in the Kahn test and a colloidal gold curve of 0011211000

The patient refused to see an ophthalmologist In June, when an attempt was made to transfer her to a syphilologist nearer her home, treatment was discontinued

CONCLUSION

A case of pain in the breast due to neurosyphilis is presented, which is believed to be the first of its kind recorded in the literature

GRANULOMA CUTIS CALCINOSUM FOLLOWING INJECTION OF CALCIUM LEVULINATE

CHAIM BERLIN, M D
TEL-AVIV, ISRAEL

A peculiar local untoward incident following an intravenous injection of calcium levulinate came to my observation recently At the site of injection a nodular eruption, which took the appearance of granuloma annulare, developed

REPORT OF A CASE

M D, a boy aged 17, was admitted to the hospital in July 1945 because of peritoneal tuberculosis accompanied with ascites He was given roentgen therapy and intravenous injections of calcium levulinate, with much improvement in his condition Once during such an injection he experienced a painful sensation and slight local redness The physician, fearing a subcutaneous infiltration, stopped the injection immediately But no infiltration occurred, and the redness and tenderness subsided within several hours The next day, a papular eruption appeared at the site of injection When the patient was seen by me, six days after the incident, the left cubital area presented a plaque measuring 1 5 by 1 cm, consisting of pinhead-sized to match head-sized, slightly raised, firm, closely aggregated and partly coalesced nodules with smooth surfaces The color was pinkish to yellowish and became lighter on diascopic pressure The lesions were neither pruritic nor painful Most of the nodules were arranged in a horseshoe fashion, and the plaque closely resembled the picture of granuloma annulare (fig 1) No change was observed during the next two weeks The plaque was then totally excised, and the microscopic examination made by Dr Karplus confirmed the tentative diagnosis of deposits of calcium A report on the examination follows

"Corresponding to the nodules distinctly seen on gross observation, there were foreign body granulomas in the form of tubercles with many giant cells of middle size in the deeper layers of the cutis Most of the cells were fibroblasts, and there

From the Department of Dermatology, Hadassah Municipal Hospital

cells in the superficial portion of the corium Sharply circumscribed, rounded tubercles were present in the deeper portion of the corium These were composed of syncytial masses of lipid-laden epithelioid cells and a few Langhans' giant cells Lymphocytes were absent, and there were no signs of caseation There were no changes in the epidermis or superficial part of the corium to account for the clinical appearance of follicular papules, although serial sections of two biopsy specimens were studied The pathologic diagnosis was Boeck's sarcoid

Cutaneous lesions persisted unchanged during a two month observation period, which terminated when the patient had an acute schizophrenic episode, which necessitated her transfer to a psychiatric institution

COMMENT

In classifications of cutaneous tuberculosis such as that proposed by Michelson and Laymon,[7] prognosis has been determined by the clinical features of the eruption, and the results of histologic and immunologic studies have been considered of less importance The morphologic aspect of the lesion may, however, prove to be an unreliable index of prognosis On the basis of its clinical appearance, the eruption in the case under discussion was classifiable as a "form which tends to heal relatively rapidly" (lichen scrofulosorum), although laboratory studies, examinations of histologic structure and tuberculin testing suggested a chronic and progressive process Unquestionably, prognosis for the various types of tuberculids depends to a considerable extent on the resistance of the host to the underlying visceral tuberculosis Consideration of all the clinical, bacteriologic, immunologic and histologic findings in any given case is necessary for adequate evaluation of the patient's resistance The relative importance of each of these factors in determining prognosis has not yet been clearly defined, and emphasis on morphology or any other single factor is therefore unjustified In addition, numerous reports attest the fact that lichen scrofulosorum of typical gross and microscopic morphology may occur in conjunction with other tuberculous lesions, i e, lupus vulgaris, which have widely different prognostic significances

SUMMARY

A patient exhibiting lesions clinically typical of lichen scrofulosorum presented histologic and immunologic features of cutaneous sarcoid, as well as sarcoidal involvement of the uveal tract, salivary glands and lungs

Implications relative to the classification of cutaneous tuberculosis are discussed

Mycosis Fungoides (with Vertebral Involvement, Treated with Nitrogen Mustard) Presented by DR BEN A NEWMAN

R G, a white woman aged 59, has had a recurrent generalized eczematoid dermatitis for the past eleven years This condition has been treated with several courses of roentgen radiation In 1945 a diagnosis of mycosis fungoides was made from a biopsy specimen During one and one-half years she received roentgen therapy, a course of diphtheria toxoid and injections of antireticular cytotoxic serum without benefit She was admitted to the hospital again on Nov 1, 1946 At that time, she presented a generalized dermatitis involving the entire cutaneous surface, consisting of eczematoid infiltration and plaques

The patient was given two courses of nitrogen mustard (three injections of 6 mg each) during a two week period One week after the first injection, involution of the lesions occurred and also pruritus At the end of three weeks her skin was entirely clear except for a bandlike vesicular patch extending across the right scapula and over the right breast When the vesicular patch became visible, after the generalized dermatitis disappeared, a diagnosis of herpes zoster was made Roentgenologic examination of the spine at this time showed a compression of the fourth dorsal vertebra

The blood cell count, urine and results of the blood chemistry determinations were normal

Mycosis Fungoides (Treated with Nitrogen Mustard) Presented by DR. BEN A NEWMAN

R C, a white woman aged 58, has had recurrent generalized pruritus for thirty years For the past three years, she has been under constant care at the Los Angeles County General Hospital and has been refractory to roentgen irradiation for the past year On Jan 2, 1947, she was admitted to the Cedars of Lebanon Hospital for nitrogen mustard therapy At that time, she presented a generalized eruption consisting of bright red, thick, scaly infiltrated patches

The infiltrate disappeared after three injections of nitrogen mustard, but further therapy was restricted because of a drop in the leukocyte count The pruritus has decreased considerably, and the infiltrated patches are now pinkish and softer

Mycosis Fungoides (Treated with Nitrogen Mustard) Presented by DR BEN A NEWMAN

F S, a white man aged 62, has had a chronic dermatitis of both hands for twelve years Since the beginning, he has had numerous attacks of a generalized eczematoid dermatitis. In each instance, roentgen irradiation was the only agent that produced involution of the eruption, in spite of considerable topical therapy

The present attack began three years ago with generalized eczematoid dermatitis During this period, the patient received repeated courses of low voltage roentgen

were only a few inflammatory elements Sections stained with hemalum and eosin revealed in the center broad, calcified, collagenous bundles (fig 2) The fundamental color of the tubercle was somewhat bluer than was that of the surrounding tissue A Kossa stain gave wide impregnation of silver in the fibers throughout the tubercle The nolular occurrence of the process indicated an embolic process, that is to say, during the injection calcium reached the skin through small arterioles"

COMMENT

This strange form of calcinosis is certainly extremely rare On the other hand, it is obvious from the history and the histologic observations that the eruption was a consequence of the injection of calcium levulinate However, nothing definite can be said about the mechanism of the eruption The passage of a calcium compound outside the vein usually produces severe, nonspecific, painful infiltration But in this case it must be assumed that even during the puncture particles of calcium succeeded in reaching the skin There they were dispersed, to cause the formation of reactive nodules

SUMMARY

A case of calcinosis of the skin following an intravenous injection of calcium levulinate is reported Around the site of the injection in the cubital fossa an immediate erythema, accompanied with pain, developed This rapidly subsided and was followed by a group of asymptomatic, small, firm, pinkish nodules, which, with their semicircular arrangement, resembled granuloma annulare Histologically, calcified collagenous bundles and foreign body giant cells were found

REACTIONS TO BISMUTH SODIUM TRIGLYCOLLAMATE (BISTRIMATE®)

LOTHAR WIRTH, M D
RENSSELAER, N Y

Bismuth sodium triglycollamate (bistrimate®), a new oral bismuth compound for oral administration, has been found effective in systemic bismuth therapy [1] Only minor side reactions, which were limited to the gastrointestinal tract, were observed—reactions which, after dosage had been temporarily reduced, did not interfere with continued administration of bismuth sodium triglycollamate [2] More recently, however, I saw 2 patients exhibit reactions to bismuth sodium triglycollamate which prevented continuation of treatment with this drug, although bismuth subsalicylate given parenterally was tolerated well I thought it might be worth while to report these cases

CASE 1.—A 70 year old man with tertiary syphilis of the central nervous system was started on treatment with bismuth sodium triglycollamate in the recommended dosage of 50 mg three times daily after meals On the third day of this regimen he exhibited an edematous lower lip, bluish discoloration of its mucosa

1 Lehman, R A, and Fassett, D W Experimental and Clinical Studies on Oral Bistrimate (Sodium Bismuth Triglycollamate) for Systemic Bismuth Therapy, Am J Syph, Gonor & Ven Dis **31** 640 (Nov) 1947

2 Gross, E R, and Wright, C S Oral Bismuth Therapy in Syphilis and Various Dermatoses, read before the Pennsylvania Medical Society, Philadelphia, Oct 8, 1946

irradiation with partial relief, but there were prompt recurrences on discontinuance of therapy During the past year, he lost about 15 pounds (7 Kg), chiefly from loss of sleep because of pruritus He was admitted to the hospital on Jan 25, 1947, for nitrogen mustard therapy

Physical examination revealed a generalized eruption consisting of patches and plaques of erythematous eczematoid lesions and erythematous dry infiltrated plaques

On February 3, treatment with nitrogen mustard was started He was given four intravenous injections of 6 mg each in five days On the sixth day, there was visible involution of the lesions and decrease in the itching The patient now presents some residual faint pinkish spots on the legs at the site of the former lesions Histologic examination of the tissue showed the typical polymorphous infiltrate with scattered histiocytes

DISCUSSION OF CASES OF MYCOSIS FUNGOIDES

DR L F X WILHELM I saw a great improvement in the woman who was at the County Hospital for a number of years, but the appearance of her lesions was not altered materially, and when I questioned her about the itching she said that it was still bad I think that we should see these patients again in thirty or sixty days

DR J R SCHOLTZ There appears to be no question that many of the patients treated with nitrogen mustard have been given symptomatic relief and that involution of the skin lesions is substantial Even though there is no assurance of the permanence of the results, the method certainly affords important palliative treatment in a difficult situation

DR A F HALL One patient denied having had any vesicles in the zoster area This zonal eruption appeared in the form of plaques which were themselves suggestive of mycosis fungoides It is of considerable interest to conjecture whether this is herpes zoster If it is, should one assume that it is due to the same virus that produces herpes zoster in otherwise well persons, or is this by any chance a zonal manifestation of mycosis fungoides, or, third, is it just that the eruption takes the form of mycosis fungoides in a person afflicted with that disease?

DR CLEMENT C COUNTER Is the fact that the patient had nausea and vomiting for two days after her injection considered sufficient reason for discontinuing administration of nitrogen mustard, or can it be used again in spite of this reaction?

DR BEN NEWMAN In reply to Dr Hall concerning the zoster-like distribution of the eruption in the first case, this patient had a generalized involvement of the skin with no clear areas except the palms, soles and face One week following a course of nitrogen mustard—methyl-*bis* (β chloroethyl) amine therapy, the entire skin was clear except for the wide patches of lesions that are now present Minute vesicles were scattered among these confluent, erythematous, eczematoid and slightly infiltrated plaques, following the course of the right fourth dorsal nerve The patient had been complaining of radicular pain in this area for two weeks, as well as generalized itching When I became aware of this new lesion, a roentgenogram was taken This showed a destruction of the fourth dorsal vertebra It has been my impression that this patient has a lymphomatous involvement of the vertebra, with radiculitis and herpes zoster, the zoster reaction in a skin already overwhelmed with mycosis fungoides was soon replaced by the lymphomatous response of the skin I believe that this lesion is mycosis fungoides, following a radicular distribution

and continuous salivation Food intake was very difficult Treatment with bismuth sodium triglycollamate was discontinued, and it took about ten days for the symptoms to subside It was then discovered that the patient had dissolved the tablets of the drug on his tongue, as he could not swallow pills Treatment was resumed, without ill effect, with parenteral administration of bismuth subsalicylate

CASE 2—A 55 year old man with syphilitic valvular heart disease was given bismuth sodium triglycollamate in the usual dosage He returned two weeks later with a generalized papulopustular eruption, which cleared within three weeks after treatment with the drug was discontinued Further treatment with bismuth sodium triglycollamate was then tried, at which time the eruption recurred After one month without therapy, treatment was resumed, without further difficulties, with bismuth subsalicylate administered intramuscularly

It seems appropriate to instruct patients not to dissolve bismuth sodium triglycollamate on their tongue, as this procedure undoubtedly predisposes to reactions within the oral cavity

I think the second case is unusual in that a cutaneous eruption occurred in a patient receiving bismuth sodium triglycollamate, while bismuth subsalicylate given parenterally was tolerated well

PENICILLIN-RESISTANT EARLY SYPHILIS

Report of a Case

LOUIS WEXLER, M D *
AND
ROBERT N BUGG, M D *
NEW YORK

CAPTAIN HERBERT V ADAMS
AND
LIEUTENANT COLONEL ALLEN D SMITH
MEDICAL CORPS, ARMY OF THE UNITED STATES

Since the inauguration of penicillin therapy, resistant early infectious cases have rarely been encountered To our knowledge only 1 such case has been reported [1]

It is the purpose of this paper to present a case of penicillin-resistant early syphilis

REPORT OF A CASE

A 24 year old Negro was admitted to the Dermatology and Syphilology section on Sept 5, 1946 because of a penile lesion of six weeks' duration After appearance of the lesion no treatment had been sought for three weeks At that time the patient had received one intravenous injection of arsphenamine from a private physician, after which treatment the lesion became swollen and painful and did not heal No further treatment was obtained until his entrance to the hospital At admission, dark field examination revealed Treponema pallidum

From the Dermatology and Neurosyphilis Center, Oliver General Hospital, Augusta, Ga

* Formerly Captain, Medical Corps, Army of the United States

1 Tyson, W G Early Syphilis Resistant to Treatment with Penicillin Report of a Case, J Invest Dermat 6 279 (Oct) 1945

Nausea and vomiting usually cease after the first two injections The chief contraindication to further therapy is a significant drop in any of the elements of the blood

The patients presented this evening are part of a group of 6 patients with mycosis fungoides receiving treatment and under observation at the Cedars of Lebanon Hospital All the patients were roentgen-ray-resistant, and all have shown a favorable response to nitrogen mustard The degree of response has varied At present, my co-workers and I are studying various dosage and interval schedules of therapy I do not believe that nitrogen mustard will cure this disease, but it has already provided immeasurable relief to some patients With a chemical capable of destroying certain types of neoplastic cells, even temporarily, it is probable that we may be heralding an era of a new method of management (chemotherapeutic) of malignant disease

Darier-Roussy Sarcoid (Gumma?) Presented by DR STANLEY O CHAMBERS and DR STANLEY C ANDERSON

Granuloma Annulare of the Arms and Face. Presented by DR MOLLEURUS COUPERUS

Radiodermatitis with Ulceration (Successfully Treated with Radon Ointment) Presented by DR JUD R SCHOLTZ

Acrosclerosis (Favorable Response of Ulcers to Neostigmine Hydrobromide). Presented by DR MOLLEURUS COUPERUS

DISCUSSION

DR NELSON PAUL ANDERSON I am treating a patient with Reynaud's syndrome and sclerodactylia who has had ulcerations of the finger tips He weighs about 210 pounds (95 Kg) and is 6 feet 2 inches (188 cm) tall We have given him five injections of tetraethylammonium bromide It is apparently a potent drug, because shortly after the injection, which is given very slowly, he can feel increased warmth in the hands and feet and is able to move them with more freedom Just what the ultimate outcome will be, I cannot say, but I do feel that the treatment may at least lead to some useful information It may possibly give an indication as to which are the favorable cases for sympathectomy I doubt that this drug attacks the fundamental perivascular system itself In the October 1946 issue of *Surgery* there is an excellent article on this drug I warn you not to administer the drug when in a hurry, because it is necessary to spend an hour or two with the patient

A Case for Diagnosis (Carcinoma? Pseudoepitheliomatous Hyperplasia Associated with Infectious Mononucleosis and Primary Tuberculous Complex?) Presented by DR J WALTER WILSON

Psoriasis (Hypertrophic Lichen Planus?) Presented by DR NELSON PAUL ANDERSON

A Case for Diagnosis (Lupus Erythematosus?) Presented by DR H C L LINDSAY

and Kahn and Wassermann tests of the blood elicited positive reactions, a diagnosis of primary syphilis was made, and penicillin therapy was started, 100,000 units every three hours for eighty injections During the period that the patient was receiving therapy there was no improvement in the appearance of the chancre On the last day of treatment the prepuce became edematous and nonretractable, and concurrently a generalized, papular, erythematous, discrete, symmetric eruption appeared The papules ranged in size from that of a match head to that of a pea On the next day the eruption was more pronounced and more generalized Dark field examination of one of the papular lesions revealed it to contain living T pallidum, and the titer in the quantitative Kahn test at that time was 20 Kahn units

The patient was then started on a course of oxophenarsine hydrochloride (mapharsen®) and bismuth subsalicylate injections Two weeks later, after the patient had received four injections of oxophenarsine hydrochloride of 0 06 Gm each and two injections of bismuth subsalicylate, 0 2 Gm each, all cutaneous lesions had disappeared, and the titer in the Kahn test was 3 Kahn units At that time the patient was discharged with instructions to report to the local treatment center for completion of therapy, and further contact with the patient was lost

The penicillin used was a crystalline sodium penicillin supplied by the Army and of current stock, the lot number was not recorded at the ward However, concurrent usage in the cases of other patients with primary and secondary stages of syphilis revealed no further deviation from the expected result

SUMMARY AND CONCLUSIONS

A case of penicillin-resistant primary syphilis is presented After having received 8,000,000 units of penicillin, the patient acquired secondary syphilis After this development the response to heavy metal therapy in this case was very favorable

ENDEMIC FAVUS IN TEXAS

BEN R EPPRIGHT, M D
AND
C H McCUISTION, M D
AUSTIN, TEXAS

A white woman aged about 36, consulted us on Nov 3, 1947, because of an eruption of the scalp, with loss of hair

She stated that the disease had begun about one year previously with localized scaliness and mild itching of the scalp The eruption gradually spread, the scaling became severer, and loss of hair ensued in the areas in which the eruption had been present the longest Although born in Poland, the patient had come to Texas twenty-five years ago and had not been out of the state since that time Both the patient and her parents stated that she had had no scalp disease of any kind prior to about a year ago and that no one else in the family had had any disease of the scalp She knows of no contact in the last few years with anyone from foreign countries

Examination revealed a woman of about the stated age, somewhat underweight The entire scalp was involved with scaling and numerous crusts and scutula The scutula were cup shaped, with the concave side facing upward Hairs, dull and

Porokeratosis of Mibelli Presented by Dr Samuel Ayres Jr

N A a white boy aged 12, presents a lesion on the right side of the neck, approximately the size of a nickel with a narrow, elevated border which appears to be made up of individual elements showing dry, hyperkeratotic scaling along the top of the border The lesion developed about nine months ago There is one small pinhead-sized nodule within this circle, and there is a slightly lichenified appearance on the surface of the area enclosed by the ring

Histologic examination reveals that the most characteristic feature is in the epithelial layer, the central portion of which shows hyperkeratosis and parakeratosis with a follicle filled with keratin The prickle cell layer immediately surrounding the follicle is acanthotic, giving the appearance of a ridge with a furrow The basal cell layer is intact, with some perivascular infiltrate in the upper cutis

DISCUSSION

Dr Kenneth L Stout Clinically, I thought this was granuloma annulare, and when I looked at the section I found nothing to change my mind

Dr L H Winer I agree clinically with the diagnosis, but the histologic section did not show porokeratosis of Mibelli Of course, every section of porokeratosis of Mibelli would not necessarily show the characteristic histologic appearance Of interest in the slide are the porokeratotic scales These have been reported adjacent to the hyperkeratotic disks of porokeratosis of Mibelli and are located at the periphery of the disks of porokeratosis However, the infiltration of the cutis was deep and stellate in arrangement I could not see any collagenous necrosis I would suggest another biopsy

Dr Nelson Paul Anderson I think the slide is fairly typical of porokeratosis of Mibelli I think a good deal of variation is seen, depending on (1) the sites of biopsy and (2) where the actual slide is sectioned I happen to have Mibelli's original article on porokeratosis, and I am sure that from a number of photomicrographs in this article one would accept the section as typical

her closely but could get no history of the ingestion of arsenic I simply think that we have to decide whether this entire picture should be included in a single dermatologic entity, which I rather doubt at present

DR HAMILTON MONTGOMERY, Rochester, Minn I thought this was a case of congenital defect She has a flat nose You could not call it a congenital ectodermal defect with the changes in the tongue, but we have seen cases of endodermal and ectodermal changes merging together She did not have changes in the teeth but had changes in the palms that might indicate an ectodermal defect, as would the changes in the neck In addition she has apparently had a dermatitis which does not belong with that picture I would suggest that her family history be investigated

DR FRANCIS W LYNCH, St Paul, Minn I thought of the possibility of an ectodermal defect, but the mucosal changes were too great The family history is normal as far as could be learned on brief questioning

Pityriasis Rubra Pilaris Presented by DR S ROTHMAN and (by invitation) DR J H MCCREARY

Eczema Vaccinatum Presented by DR F E SENEAR and staff

A Case for Diagnosis (Secondary Vaccinia [Autoinoculation]) Presented by DR F E SENEAR and staff

DR SAMUEL AYRES JR My experience with this disease has been limited to 1 case, and in that instance total destruction was the only method that appeared to be successful—either excision or destruction, with electrodesiccation and curettage I think this is the method of choice

DR NELSON PAUL ANDERSON In Cleveland, at the last meeting of the Academy, Dr Cole showed a patient who had perhaps fifty lesions of porokeratosis of Mibelli around the face and neck Under moderate vitamin A dosage, 25,000 units three times a day, there had been at least a 75 per cent regression, according to the photographs and the condition of the patient Dr Allen in San Diego has a whole family with porokeratosis of Mibelli, with one patient who had ten to twelve lesions on the neck, and there has been dramatic improvement with vitamin A therapy

Chronic Urticaria of Seventeen Years' Duration Presented by DR NELSON PAUL ANDERSON

Tinea Capitis Favosa in a Girl Aged Eleven Years, a Native of the Island of Rhodes Presented by DR M E OBERMAYER and DR J WALTER WILSON

Favus of the Scalp Presented by DR HAROLD E ANDERSON and DR J WALTER WILSON

M K, a white woman aged 28, has had a fungus infection of the scalp continuously since infancy Nine siblings and two paternal aunts are said to have been similarly infected, in some of whom the infection is still present When the patient was 6, the entire family was treated at the Mayo Clinic with roentgen epilation, some were cured This patient states that such epilation was carried out three times in her case Many other attempts have been made at treatment, with uniform lack of success

Examination under Wood's light revealed a dull greenish fluorescence extending along numerous hair shafts for 2 to 3 cm from the scalp Potassium hydroxide preparations of such hairs showed hyphal threads within as well as around the hair shaft, together with chains of spores and occasional air bubbles Culture was obtained on Sabouraud's glucose agar, but only on the third attempt because of secondary involvement with bacterial and nonpathogenic fungi Sufficient growth has been obtained, however, to enable microscopic diagnosis of Trichophyton schoenleini to be made

No treatment has been instituted to date

DISCUSSION OF TWO PRECEDING CASES

DR H P JACOBSON I saw only 1 of the 2 cases The scalp lesions in that patient consisted of several roughly circular patches of inflammatory alopecia with some scarring but no scutula The culture is characteristic The presenter states that topical treatment has proved of no avail My therapeutic suggestion would be topical employment of 15 per cent thymol in oil of thyme The scalp should be shaved once a week, and the thymol application should be put on once daily with an applicator I have had success in the management of tinea capitis (microsporic and trichophytic) with this fungicidal agent

DR. L H WINER The first patient did not have scutula but did have the typical atrophic scars of favus In the second case scutula were present, and on being daubed with alcohol they became yellow, which is a characteristic of favus

Corson F F Chloracne 466
Lupus erythematosis of face with possible traumatic or trophic causation 125
Necrobiosis lipoidica with hypertrophic case for diagnosis 967

DR H C L LINDSAY In 1913 Dr Sabouraud showed some patients who had had favus since their earliest days He stated that he had treated the parents of these patients for favus and, furthermore, that in a study of the records of St Louis Hospital, Paris, it was possible to prove that favus had been present in the ancestors of these patients for generations At this time Dr Sabouraud was epilating the scalp of patients with favus with roentgen rays as a preliminary treatment Success in treatment of favus among illiterate persons is most difficult Fortunately, hairs in which favus is growing are not so brittle as when they are invaded by small-spored ringworm Thus favus hairs can be plucked manually Favus was not infrequently seen at St Louis Hospital, and a considerable number of the patients had permanent scars and alopecia in patches

DR CLEMENT E COUNTER Is the temporary epilation of the scalp expected to cure favus? One of these patients presented tonight has had epilation three times She still has the disease

DR BEN NEWMAN In reference to temporary roentgen ray depilation, our attention should be directed to two important considerations one, that in the past number of weeks approximately a dozen cases of Microsporum audouini infection of the scalp have been uncovered in and around Los Angeles and that we may expect an epidemic form of the disease, if the same pattern is followed here as has occurred in all the larger cities throughout the county, two, that heretofore it has not been necessary, nor has it been the custom, to employ roentgen ray depilation in the treatment of tinea capitis in this area Hence, if we desire to control the spread of this epidemic, we must recognize the need for such depilation and establish this procedure as a proper and customary type of therapy in this community to avoid medicolegal complications Certainly, the merits and need for depilation in Microsporon audouini infections of the scalp require no discussion among dermatologists

DR H C L LINDSAY A few years ago efforts to demonstrate favus fungus in hairs by stain were not always successful Hot carbolfuchsin was used to stain, and dilute nitric acid was used to decolorize Supposedly the decolorizing of the fungi should be slower than that of the other stained material Unfortunately, the hair would decolorize at approximately the same speed Accidentally, I placed some partially decolorized stained hairs containing favus in a watch-glass container which was partially filled with aniline oil I forgot about these hairs for a week When I examined them with the microscope, the fungus in certain parts could be seen retaining the dye, while the rest of the field was clear

DR NELSON PAUL ANDERSON No one has ever seen favus develop in an adult If complete epilation had been carried out on this woman and the disease cured, she would not have been reinfected when an adult Sabouraud said he had never seen a case of favus transferred to an adult I am convinced that certain types of favus are curable by manual epilation I have had 3 cases of favus, 1 involving the thumbnail, 1 involving the scalp of a little girl and 1 involving the scalp of the aunt of the little girl The mother faithfully epilated all the hairs from the scalp of the daughter and faithfully scraped her own thumb nail Both patients are now well The scalp of the maternal aunt still presents widespread involvement

DR J WALTER WILSON I am glad that Dr Obermayer and Dr Anderson afforded me the opportunity of carrying out the mycologic studies in these 2 cases, which I believe are representative of favus under treatment and scrupulous cleanliness Growth of T schoenleini was obtained only with difficulty from the adult because of the presence of other nonpathogenic fungi, which repeatedly suppressed

its growth The dull greenish fluorescence extending for 2 or 3 cm distally along the hair shaft is typical The adult is able to trace the disease through her father to his parents, who came from Luxembourg, the child's parents came from the Island of Rhodes

DR HAROLD E ANDERSON My patient, the adult in the second case, had much heavy, dry scaling extending along and matting together the hair shafts when I first saw her It reminded me of what is called tinea amiantacea A microscopic examination of potassium hydroxide preparation of hairs and scales selected for study revealed numerous mycelia and spores Secondary invaders overgrew the culture mediums, but Dr Wilson was finally able to isolate T schoenleini The familial tendency, the clinical appearance and the cultural study all are typical of tinea favosa She has already had roentgen ray epilation at least three times, once at the Mayo Clinic and once at the University of Iowa She was treated at the Mayo Clinic in 1924 A direct microscopic examination of hairs at that time revealed fungi, but the result of the cultural study was not reported The postepilation therapy was carried out at home in Iowa, and apparently the parents were not diligent enough with this therapy

Basal Cell Epithelioma (Morphea Type) Presented by DR SAMUEL AYRES JR and DR JOSEPH I MIROVICH

DISCUSSION

DR A F HALL In several cases in which I have tried treatment by radiation the condition has proved recalcitrant, I think the lesion has to be destroyed in some other way, such as by cautery

DR ANKER K JENSEN At the risk of repetition, I would again say that in the management of cutaneous malignant growth we must carry out the radical measures first Conservative management is at no time justified in the handling of cutaneous neoplastic disease This applies both to radiation therapy and to surgical procedures I confess partiality to cautery surgery, but of course I am also employing radiation My radiation dosages are much heavier than those employed in the present case I am inclined to agree with Dr Hall that the epithelioma in our present patient has the aspects of a morphea-like lesion, and this could possibly be a factor in its apparent radioresistance There is, of course, little if any danger of distant metastasis from this lesion, it being a basal cell growth The clinical picture at present, however, indicates a steady but progressive extension and activity, and unless eradicated completely it will probably result in a rodent ulcer I recommend radical surgical treatment by means of cautery

DR L H WINER Basal cell carcinomas of the scalp are occasionally of sebaceous gland origin and as such are radioresistant I agree with the preceding discussers that excision followed by skin graft is the treatment method of choice

lated, papular hyperkeratotic eruption about the center of the trunk, on the anterior and posterior axillary folds and in the pubic region There is also involvement about the inguinal regions and the lower part of the abdomen and in the bends of the elbows The center of the chest and back and the sides of the neck are clear

Histologic examination of the tissue showed a verrucous acanthotic process, with one area where there were four nests of cells just beneath the epidermis, like a nest of melanoma cells Many of the epidermal cells were vacuolated

Treatment has consisted of administration of massive doses of vitamin A, with great improvement The patient has recently been using sodium thiosulfate soaks at the suggestion of Dr E S Lain, of Oklahoma City

DISCUSSION

DR L H WINER My clinical impression was the close resemblance of this case to parapsoriasis, especially in regard to the lesions on the abdomen and flanks However, the verrucous lesions in the right axilla were characteristic clinically of acanthosis nigricans, as was the histologic section Histologically, one cannot differentiate the benign form from the malignant form of acanthosis nigricans

Urticaria Pigmentosa Presented by DR STANLEY O CHAMBERS and DR STANLEY C ANDERSON

Verruca Plana of the Face Treated by Posthypnotic Suggestion Presented by DR MAXIMILIAN E OBERMAYER

D P, an unmarried woman aged 21, noticed the appearance of a group of flat warts on the right side of her chin two years ago The dermatologist who was treating her at that time with fractional doses of roentgen rays for acne vulgaris intimated that the warts would probably disappear with continuation of treatment However, the verrucae spread rapidly, and when the course of roentgen therapy had been completed they involved most of the face Various dermatologists removed the ordinary warts which appeared on the fingers of the right hand by means of electrodesiccation Injections of bismuth subsalicylate in oil, given over a period of eight months, as well as subsequent applications of peeling ointments and solid carbon dioxide and the use of lotions in combination with ultraviolet irradiation, had no effect on the verrucae planae of the face

When I saw the patient for the first time, on Dec 5, 1946, her face was studded with verrucae of the flat juvenile type and lesions were also present on the forehead, the anterior portion of the scalp and the sides of the neck Most of the right side of the face and neck was covered with confluent plaques, while the lesions on the left side were more scattered

When it became clear that the oral administration of bismuth (sobisminol mass) and the local use of a 20 per cent solution of podophyllin in acetone had failed to benefit the patient, her mother was told that I had no other therapeutic suggestions, and the irrational behavior of warts was discussed and illustrated by an account of Dr Bloch's experiments in Zurich A few days after this discussion, the mother suggested that arrangements be made for treatment by posthypnotic suggestion I agreed In order to complete my record of the case, biopsy of a lesion was performed The section showed the features typical of verruca plana juvenilis

induratum without ulceration 953
multiforme 946

The patient was then referred to Dr Ralph R Greenson, certified by the American Board of Psychiatry She saw Dr Greenson only three times, at weekly intervals Two weeks after the last consultation, in accordance with a suggestion made during light hypnotic sleep, all verrucae had disappeared

The skin today reveals no trace of the lesions

DISCUSSION

DR A F HALL I think we will all admit that the warts either went away spontaneously or were cured by suggestion, to believe the former demands too much of coincidence I think we will admit that Rasputin, the "black monk of Russia," controlled the czarevitch's hemophilia by suggestion I think most of us, if not all, can cite examples of warts that have been cured by prayer or wishing or out and out suggestion, either in our childhood or in our practice, since Bloch put this type of treatment on a respectable basis, I expect that "suggestion" is the proper word It is intriguing to conjecture regarding the mechanism involved I remember seeing an article on the subject by Karl Zwick in the ARCHIVES (Zwick, K Hygiogenesis of Warts Disappearing Without Topical Medication, *Arch Dermat & Syph* **25** 508 [March] 1932) The author's conjecture is that the treatment of warts by magic and suggestion often includes traumatism of the wart, e g, by rubbing it with a potato or a penny or an apple He also mentions the cure of warts by suggestion without touching the wart He feels that the factor which the two types of approach have in common is perhaps that the wart is unfavorably affected by tissue juices, he advances this theory, because in the inoculation of warts, if any of the innoculum gets into the subcutaneous tissue, a new wart will not appear He further points out that, by psychic methods, extravasation of serum and diapedesis of blood cells can take place under hypnosis He thinks it is through some such mechanism as this that warts may be influenced Were I to "take it from there," I should hypothecate that if there is a tissue fluid or some substance in the corium inimical to warts, it may be the same substance that makes the difference between the bleeding of ordinary tissue and the bleeding of a wart The prolonged bleeding time, seen when a wart is cut, may be due to the absence of thromboplastin in warty tissue, it may be this substance, present in the corium and absent in warts, that is inimical to the "life" of a wart One might try injection of thromboplastin into the base of a wart as treatment, in circumstances which would eliminate the factor of suggestion

DR J R SCHOLTZ In my opinion, most of the treatments that we use for warts act by suggestion, and as far as I am concerned, treatments which are harmless and do not leave scars are the most desirable I can see no therapeutic sense in using any method which causes a scar in place of a benign, harmless lesion There is no doubt that psychotherapeutic methods are effective in the treatment of warts Recently in the clinic of the Los Angeles County Hospital, a boy aged 8 years was seen with four to six large verrucae vulgares on his hands They were bright blue, and it was found that he had been treating them daily with an indelible pencil We encouraged him to continue and stated that the warts would probably disappear in about three weeks On his return a month later, all the warts were gone

DR MAXIMILIAN OBERMAYER There are two reasons for this presentation First, I believe that dermatologists should become better acquainted with the extraordinary fact that an infectious disorder may be amenable to suggestive therapy Obviously, first hand knowledge of the data in an authenticated case

Fisher A A. Dermatitis herpetiformis, arsenical keratoses and pigmentation, ulcer of leg 801

will be much more enlightening than information obtained by hearsay or from an unassimilated skimming of psychiatric literature, as the late Dr Bloch fully realized when he conducted his now famous clinical experiment with Swiss school children Second, I believe that speculation about the nature of the working mechanism underlying the indisputable results of suggestive therapy will prove of value In my opinion, it is most rational to assume that the neurovascular mechanism is involved The psychodynamic factors which lead to contraction of the capillary vessels and consequent pallor in certain emotional states are perfectly familiar Logically one may assume, then, that suggestion can produce a similar spasm of the capillaries, with consequent shutting off of the blood supply to the lesions Dr Greenson approached the problem with such an assumption in mind

Since a preliminary interview revealed no psychoneurotic features, the psychiatrist expressed the belief that while the treatment could produce no ill effects, its chance of success was small At the end of the first interview, the patient was told to imagine for a few minutes before bedtime each night that her face was covered by cold compresses and was beginning to itch and tingle At her second visit, she gave the encouraging report that she had had the sensation of itching An attempt at hypnosis was followed only by a state of deep relaxation without sleep, during which it was suggested that her face would feel cold, her skin would itch and the warts would begin to fall off The patient began the third and last consultation by stating that the warts had commenced to become scaly Once more hypnosis was attempted, and a state of light sleep was produced It was then suggested that her face would feel cold and turn pale and that the lesions would itch and fall off within two weeks The patient was awakened and told that no further interviews were contemplated because her warts would shortly disappear Two weeks later her skin was clear of all lesions

I should be the last to propose that posthypnotic suggestion be employed routinely in the treatment of verrucae On the other hand, since the shortcomings and unreliability of all the so-called approved methods of treating warts are well known, I believe that suggestive therapy should be given a trial when conventional methods have proved useless and extensive involvement has raised a problem from the cosmetic standpoint, as in this case That such therapy will succeed with only a limited number of patients is obvious and that it should be carried out only by a fully trained psychiatrist well versed in the technic and aware of the dangers of hypnotic suggestion is equally clear Certainly most dermatologists would willingly accept a dozen failures with psychotherapy rather than invite a single instance of the dermatitis actinica produced by roentgen therapy The sooner suggestive therapy is given a fair and unbiased trial by the dermatologic profession the sooner its limitations and suitability will be established

annulare or necrobiosis lipoidica diabeticorum, 859
annulare or sarcoid, 997
annulare, peculiar eruption of, case for diagnosis, 924
annulare, psoriasis, urticaria, 1016
annulare, [?] of elbows and knees, sarcoidosis, 909
annulare, subcutaneous, 1033, 1041
beryllium granulomas of skin, *1140
Coccidioidal See Coccidioidomycosis
cutis calcinosum following injection of calcium levulinate, *1204
eosinophilic, 865, 872, 881, 903
eosinophilic, of pituitary gland, lungs, bones of skull, and skin, 1007
eosinophilic, of skin, *701
eosinophilic, or erythèma elevatum diutinum, 915
eosinophilic, or periarteritis nodosa, 844
eosinophilic, progress with high voltage roentgen therapy, 880
foreign body granuloma in skin of finger 946
Fungoides See Mycosis fungoides
Inguinale, See also Lymphogranuloma Venereum
inguinale and secondary syphilis (?) 902
inguinale, circumcision and venereal disease, *341
inguinale, multiple recurrences of infectious syphilis over 19 years, 832
inguinale of mouth and genitalia, 1010
inguinale, sickle cell anemia with sickle cell ulcer of ankle, 962
inguinale successfully treated with streptomycin, 1059
inguinale treated with streptomycin, 883
inguinale with extragenital lesion on cheek, 959
Lipoid See Xanthoma
lipophagic, at sites of intramuscular injections, 470
Malignant See Hodgkin's Disease
Paracoccidioidal See Blastomycosis
pyogenicum, granuloma telangiectaticum, 911
pyogenicum, granuloma telangiectaticum, case for diagnosis, 891
pyogenicum, Kaposi's sarcoma resembling granuloma pyogenicum, 1012
Telangiectaticum See Granuloma pyogenicum
Tropicum See Frambesia
Venereal See Granuloma inguinale, Lymphogranuloma Venereum
Graves, J M Adenoma sebaceum, multiple sebaceous cysts with hypertrophy and hyperplasia of sebaceous glands, 1036
Behcet's syndrome or pemphigus 1037, 1041
Greenbaum S S Cicatrizing epithelioma of scalp, 470
Erythroplasia, case for diagnosis, 469
Pemphigus vulgaris (early or benign?), 466
Purpura annularis telangiectodes (?) improved following treatment with rutin and ascorbic acid, 827
Greenberg, S I Epithelioma of penis, 855
Grekin, R H Parafavus restricted to scrotum, report of case, *435
Groin, chronic dissecting cellulitis of groin and left foot resembling deep mycosis 904
lichen sclerosus et atrophicans, inframammary, inguinal and vulvar, 1038
Gross, E R Lichen planus atrophicus or lichen sclerosus et atrophicus, 134
Lupus vulgaris, 131
Sarcoid, solitary lesion on nose, 829
Scleroderma, 470
Gross P Keratosis follicularis, 441
Lichen planus of mouth (?) xanthoma of eyelids and tendon sheaths (associated with hypertensive cardiovascular disease), familial type, 443
Psoriasis, xanthelasma, xanthoma of tendon sheaths, 443
Purpura annularis telangiectodes, 815
Purpura annularis telangiectodes, radiodermatitis or hemostasis dermatitis, 800
Sarcoidosis with enlarged auricular and cervical lymph nodes in white woman aged 22, 970
Senile elastosis of neck (pseudoxanthoma elasticum?) 802
Gumma See Mouth Sarcoidosis, Scalp
Gums, chronic lymphedema of face hypertrophic gingivitis, rosacea 1026
hyperplasia of due to use of dilantin sodium (diphenylhydantoin sodium) 87
leukonychia and hyperpigmentation of gums and lips, case for diagnosis 921
Gustafson M H Acrokeratosis verruci formis 912

Anaphylaxis and Allergy—Continued
disseminated and circumscribed neurodermatitis treated with phenindamine (thephorin®), *390
histologic changes in sensory nerves of skin in herpes zoster, *641
virus-pyogen sequence, interrelationship in inflammatory dermatoses, clinical features, *261
pyogen allergic dermatitis, 121
Anderson, H L Favus of scalp, 1219
Anderson, H T Dermatitis herpetiformis, 133
Localized lymphedema, case for diagnosis, 134
Pityriasis lichenoides chronica (Juliusberg) or urticaria pigmentosa, 125
Scleroderma, 126
Yaws, tertiary, 133
Anderson, J W Treatment of lupus vulgaris with calciferol (vitamin D_2), *614
Anderson, N P Acanthosis nigricans, 1221
Chronic urticaria of 17 years' duration, 1219
Erythema induratum or nodular vasculitis, 1218
Psoriasis (hypertrophic lichen planus?) 1217
Anderson, S C Darier-Roussy sarcoid (gumma?), 1217
Urticaria pigmentosa, 1222
Andrews, G C Chronic discoid and lichenoid dermatosis, 1004
Dermatitis factitia, dystrophy of nails and keloids of palms and soles, 842
Fox-Fordyce disease, alopecia areata, 1010
Hemangiopericytoma, case for diagnosis 966
Lymphocytoma 1011
Moniliasis, 843
Multiple keloids or dermatofibrosarcoma protuberans (Hoffmann), 966
Pemphigus vulgaris or dermatitis factitia 1006
Poikiloderma or localized scleroderma 993
Pseudoxanthoma elasticum, case for diagnosis 1015
Syphilis or tuberculosis cutis of buttock 1027
Androgens, Therapy See Fox-Fordyce Disease
Anemia, sickle cell, with sickle cell ulcer of ankle granuloma inguinale, 962
sickle cell, with ulcers on legs, 1042
Anesthesia solid carbon dioxide as anesthetic in electrodesiccation of cutaneous blemishes 797
Anesthetics See Anesthesia
Anetoderma See Atrophy
Aneurysm aortic, aneurysm of transverse aorta 952
Angina, Monocytic See Mononucleosis, Infectious
Angioblastoma or endothelial tumor 1039
Angiokeratoma, 1033
Angioma, case for diagnosis, 823
combined simple and cavernous angioma 828
resembling idiopathic multiple hemorrhagic sarcoma, 803
serpiginosum case for diagnosis, 1058
unilateral vascular nevus angioma serpiginosum or Schamberg's disease 864
vascular nevus, hemangiomas of left leg and thigh 130
venosum racemosum, cavernous hemangioma 1018
Anhidrosis See Sweat Glands
Ankle See also Foot
tuberculosis colliquativa of, 447
Anomalies See Abnormalities and Deformities
Ansell, H B Basal cell epithelioma, of nose forehead left eyebrow and left upper eyelid 947
Antibiotics, evaluation of bacitracin in local treatment of pyogenic infections *106
Antibodies See Antigens and Antibodies
Antigens and Antibodies See also Immunity Lipoids and under specific antigens and reactions
nature of antigens and antibodies in serology of syphilis *217
Antimony and Antimony Compounds Therapy See Mycosis fungoides
Anus lichen sclerosis et atrophicus accompanied with bullous eruption involving vitiliginous areas of vulva and anus, 996
superficial epithelioma on sacral area with basal epithelioma near anus, 892
tuberculous (?) infection of buttocks and perianal region, 463
Aorta Aneurysm See Aneurysm aortic
Apparatus simple apparatus for clinical photography *638
Appel B Chronic pemphigus of eye with cicatrizing lesions of skin, 947
Sarcoid or tuberculid, 951
Xanthoma diabeticorum and lipemic retinitis due to diabetes mellitus, 952
Aphthae See Stomatitis
Apocrine Glands See Sweat Glands
Argyria See Silver, toxicity
Argyrol, generalized argyria from ingestion of argyrol, 1 ounce a week for 5 years, to prevent "colds," 868
Arms See also Extremities, etc
granuloma annulare of arms and face, 1217
keratoses of palms and soles (chronic) (caused by arsenic?), pigmentation (generalized) (caused by arsenic?), dermatitis (atopic) of hands, forearms, ankles and popliteal areas (chronic), cirrhosis (portal) of liver (chronic) (cause undetermined), 826
lichen planus and/or lupus erythematosus of lips and tongue, oriental sore of forearm, 848
Arnold, H L, Jr Erythema multiforme following high voltage roentgen therapy, review of literature and report of 3 cases, *143
Macules' of leprosy, *1148
Arsenic and Arsenic Compounds, arsenical dermatitis successfully treated with Bal 461
dermatitis medicamentosa (demerol®), Addisonian pigmentation (arsenical keratosis and pigmentation?), 1017
keratoses, due to arsenic, taken for psoriasis 931
keratoses of palms and soles (chronic) (caused by arsenic?), pigmentation (generalized) (caused by arsenic?), dermatitis (atopic) of hands, forarms ankles and popliteal areas (chronic), cirrhosis (portal) of the liver (chronic) (cause undetermined) 826
pemphiguns of conjunctiva, arsenical pigmentation and keratoses from Fowler's solution, 1033
Therapy See Penis
Arthropathy See Joints
Aschoff-Klinge Nodule See Rheumatic Fever
Ascorbic Acid, purpura annularis telangiectodes (?) improved following treatment with rutin and ascorbic acid 827
Aspergillosis, superficial mycoses of veterans, survey of 1 000 veterans with service diagnosis of dermatomycosis, *742
Asthenia tropical anhidrotic, thermogenic anhidrosis *173
Asthma See Anaphylaxis and Allergy and cataract with neurodermatitis, 993
Atabrine See Acridine Dyes
dermatitis medicamentosa (atabrine) lichen planus atrophy scars alopecia pigmentation nail changes 447
Atopic Dermatitis See Neurodermatitis
Atopy See Anaphylaxis and Allergy
Atrophoderma See Atrophy
Atrophy and pigmentation of face and neck lupus erythematosus(?), 1058
classic acrodermatitis chronica atrophicans with involvement of palms, atrophy pseudosclerodermatous plaques and fibromas 868
follicular atrophoderma of body and scalp chondrodystrophia calcificans congenita 971
idiopathic macular of skin, 948
macular or lichen planus atrophicus 853
macular or lymphogranuloma venereum 957
multiple areas of superficial atrophy of trunk macular atrophy(?) 1039
Aureomycin Therapy See Molluscum contagiosum
Autohemotherapy See Hemotherapy
Avitaminoses See under Vitamins
Axelrod A R Multiple squamous cell carcinoma of skin associated with chronic lymphatic leukemia, observations on effect of urethane therapy *625
Axilla See also Sweat Glands
supernumerary breasts in axillas (with nipple [?] on 1 only), 891
Ayres S Jr Basal cell epithelioma (morphea type), 1221
Dermatitis vegetans case for diagnosis 1218
Porokeratosis of Mibelli 1218
Rhinophyma-like eruption of face or lichemoid eruption of trunk, 1218
Traumatic marginal alopecia in white women, *1116
Ayres S III Traumatic marginal alopecia in white women *1116

Gustafson M H—Continued
Congenital ichthyosiform erythroderma, persistent notochord, 910
Granuloma telangiectaticum, 911
Lymphangiectasis of vulva, secondary to probable tuberculous salpingitis, pulmonary tuberculosis, moderately advanced, 910
Morphea or lichen sclerosus et atrophicus 912
Multiple benign cystic epithelioma, alopecia areata, 912
Nonspecific dermatitis, associated with lymphoblastoma, 910
Psoriasis arthropathica 912
Scleroderma, acrosclerosis, 913
Guthrie, M Lymphogranuloma venereum of face, case for diagnosis 123
Guy, W B Aureomycin in molluscum contagiosum, *629
Guy W H Aureomycin in molluscum contagiosum, *629

Habermann's Disease See Parapsoriasis varioliformis
Haight F K Generalized xanthomatosis, 1059
Hailey's Disease See Pemphigus
Hair clinical appraisal of cold wave process, *14
concurrent melanosis and hypertrichosis in distribution of nevus unius lateris, *155
Diseases See also Alopecia
diseases, monilethrix, case for diagnosis 1035
excessive essential hirsutism, dermatologic and endocrinologic considerations *528
familial keratosis pilaris with monilethrix-like anomaly of hair in fourth generation, maternal side, 889
Follicles See Folliculitis
Plucking See Trichotillomania
removal, early reactions following roentgen ray epilations *722
removal, manual epilation in treatment of tinea capitis, *347
severe pyogenic syocosis of beard (lymphedema? submental region) 465
Hallopeau's Disease See Acrodermatitis
Hamblen, E C Essential hirsutism dermatologic and endocrinologic considerations *528
Hamlin E M Recalcitrant pustular eruption of extremities 1056
Hamsters See Rodents
Hand L A Circumcision and venereal disease *341
Hand See also Fingers and Toes
dermatitis factitia dystrophy of nails and keloids of palms and soles 842
keratoderma punctatum of palms and soles 460
keratoses of palms and soles (chronic) (caused by arsenic?) pigmentation (generalized) (caused by arsenic?) dermatitis (atopic) of hands forearms ankles and popliteal areas (chronic) cirrhosis (portal) of liver (chronic) (cause undetermined) 826
palmar and plantar keratoses (arsenic?) (keratoderma disseminatum palmaris et plantaris)? superficial epitheliomas trunk, ulceration left small toe and left palm (squamous cell epithelioma?) case for diagnosis 913
postinflammatory cystic or keloidal lesions of hands case for diagnosis 868
progeria (?) with erythema of hands and feet partial alopecia congenital coloboma and osteoporosis 439
pustular psoriasis healed after tobacco juice soaks 896
recalcitrant pustular acrodermatitis of hands 1053
specific sensitivity to foods as factor in various types of eczematous dermatitis *1090
syphilitic juxta-articular nodes *426
trichophyton purpureum and monilia infection of hands feet and nails moniliasis of tongue 822
Hand-Schuller-Christian Syndrome See Schuller-Christian Syndrome
Hannay P W Squamous cell epithelioma and psoriasis *430
Hansen's Disease See Leprosy
Hardy M K Keratoderma punctatum of palms and soles 460
Harris R H Acrodermatitis chronicus atrophicans 891
Case of keratosis follicularis with cutaneous mucous membrane and nail changes 902
Harris, R H—Continued
Chronic urticaria due to intestinal organisms 'giardia lamblia', 'cure' following treatment with quinacrine hydrochloride 902
Folliculitis decalvans? 903
Glossy skin, Morvan's disease or possible radio dermatitis 890
Haynes, H A Jr Dermatitis herpetiformis (?) in 7 year old girl, 907
Heart, infarction sclerodactylia ? following myocardial infarction 1025
Hemangiolymphangioma of skin 948
of tongue, 943
Hemangioma See also Angioma
case of Osler's disease with hereditary telangiectasis with tumorous hemangiomas, 1059
cavernous (angioma venosum racemosum) 1018
extensive, cavernous successfully treated with solid carbon dioxide 131
of left leg and thigh, vascular nevus 130
of left thigh and leg, 946
pulsating, hepatic cirrhosis 875
radium in treatment of *717
with hereditary hemorrhagic telangiectasia 1022
Hemangiopericytoma, case for diagnosis 966
Hemopoietic System Diseases See Anemia Leukemia, etc
Hemorrhage, Cutaneous See Purpura
Hemostasis dermatitis purpura annularis telangiectodes or radiodermatitis 800
Hemotherapy See Serotherapy and Hemotherapy
Hendren, O S Identical alopecia areata in identical twins, 793
Henningsen A B Multiple nevi (adenoma sebaceum) (dermatosis papulosa nigra and fibroma pendulum) in Negro, 864
Parapsoriasis guttata with unusually small lesions 867
Pityriasis lichenoides et varioliformis acute 883
Herpes Gestationis See Dermatitis herpetiformis
zoster autohemotherapy of, results in 154 cases 636
zoster generalized with lymphatic leukemia 950
zoster histologic changes in sensory nerves of skin in herpes zoster, *641
zoster paralysis of cranial nerves complicating herpes zoster *558
Herrmann F Studies of sweating, on the mechanism of action of local antiperspirants *404
Herxheimer Reaction Syphilis
Hidradenitis See Sweat Glands
Hidrosadenitis See Sweat Glands abscess
Higdon R S Pemphigus vegetans, case for diagnosis 1036 1040
Vegetative pyoderma controlled with streptomycin 1056
Hill W R Idiopathic macular atrophy of skin 948
Molluscum contagiosum of scalp report of 2 cases *633
Mycosis fungoides or late cutaneous syphilis 948
Hirsutism See Hair excessive
Histiocytoma cutis calcified cyst, or nodular subepidermal fibrosis 457
Histiocytosis treatment of cutaneous blastomas and other diseases with nitrogen mustard *181
Hodgkin's disease case for diagnosis 857
and cutaneous torulosis 1032
cutaneous 1056
of skin 951
of skin case for diagnosis 1046
of skin (generalized erythroderma with scattered papules) 1046
treated with nitrogen mustard 972
Holtzman I N Necrobiosis lipoidica diabeticorum or granuloma annulare 859
Hopf's Disease See Keratosis
Hopkins J G Incontinentia pigmenti 848
Knuckle pads 1006
Horns cutaneous, tuberculosis luposa, cutaneous horn 946
Horvath P N Dermatitis herpetiformis in woman aged 72 years 470
Tuberculosis verrucosa cutis 823
Hubler, W R Herpes gestationis 906
Rosacea-like tuberculid of Lewandowsky 910
Hume E B Pityriasis rosea or neurofibromatosis 826
Hunt Syndrome See Herpes zoster

Babalian, L Pityriasis rubra pilaris, 950
Bacillus See Bacteria
Bacitracin, Therapy See Skin, infections
Back, follicular dermatitis of acanthosis nigricans (?), latent syphilis, adenoma of thyroid gland, 441
Bacteremia, case for diagnosis, 1031
Bacteria See Staphylococci, Streptococci Viruses, etc
Actinobacilli See Actinomycosis
Diphtheria See Diphtheria
Ducrey's See Chancroid
Hansen's See Leprosy
Leprosy See Leprosy
Necrophorus See Actinomycosis
Staphylococci See Staphylococci
Bacterid, case for diagnosis, 929
dermatophytosis, or pustular psoriasis, 1006
Bacterium See Bacteria
Baer, R L Allergic eczematous cross sensitization to paraphenylendiamine and several azo-dyes certified for use in foods, drugs and cosmetics, contamination of innocent cosmetic with paraphenylendiamine, 983
Generalized dermatomycosis (trichophyton purpureum) associated with hyperkeratosis palmaris et plantaris, 445
Baker, N L Acute disseminated lupus erythematosus in man aged 37 years, 863
Bizarre pigmentation, cause undetermined in pituitary type dwarf, 868
Contrast sweating above and below line of paraplegia, 893
Dermatomycosis (?) localized to flexural areas for 20 years, 863
Granuloma inguinale treated with streptomycin, 883
Kaposi's varicelliform eruption in infant, 869
Lichen simplex chronicus of vulva of 3 years' duration in 7 year old white girl, 868
Lymphangiectasis of vulva, 882
Meleney's ulcers or pyoderma gangrenosum, 882
Mycosis fungoides d'emblee, 868
Mycosis fungoides or psoriasis, 892
Nodular leukemia cutis in 14 month old boy, duration 8 months, 892
Nodulоulcerative syphilid of chest wall, 882
Pemphigus vulgaris, 861
Pigmented purpuric lichenoid dermatitis, 884
Rupial syphilid, 902
Scrofuloderma, Pott's disease and retrosternal abscess, 884
Seborrheic dermatitis, case for diagnosis, 893
Secondary syphilis and granuloma inguinale (?), 902
Sporotrichosis involving face and all extremities, 863
Syringocystoma, 892
BAL, Therapy See Dermatitis
Balanitis See Penis
Baldness See Alopecia
Ballin, D B Reticulum cell sarcoma 809
Barton R L Treatment of early syphilis with penicillin, report on 324 patients treated with 1,200,000 units over 7½ days, *150
Baskin, C L Porokeratosis of Mibelli, 908
Bathers seabather's eruption, *227
Bauer, T J Treatment of early syphilis with penicillin, report on 324 patients treated with 1,200 000 units over 7½ days, *150
Baumeister, C F Pain in breast due to neurosyphilis, *1203
Bazin's Disease See Erythema induratum
Beard See Hair
Bechet, P E Founding and first meeting of American Dermatological Association milestone in progress of American dermatology *24
Melanoma case for diagnosis 1008
Parapsoriasis or iododerma, 1018
Bechet Syndrome See Stomatitis aphthous
Becker, S W Concurrent melanosis and hypertrichosis in distribution of nevus unius lateris, *155
Diagnosis and treatment of pigmented nevi consideration of some of pitfalls, *14
Beerman H Hypertrophic Darier's disease and nevus syringocystadenomatosus papilliferus histopathologic study, *500
Lymphocytoma cutis, 459
Multiple recurrences of infectious syphilis over 19 years, granuloma inguinale, 832
Nevus comedonicus 130
Virus-pyogen sequence, interrelationship in inflammatory dermatoses clinical features, *261
Beinhauer, L G Promin® in treatment of certain dermatoses, *338
Bell, C D Keratosis blennorrhagica or psoriasis, 975
Necrobiosis lipoidica or tuberculoderm, 802
Benadryl,® Therapy See Prurigo, Pruritis, Scleroderma, Syphilis
Bendel, W L Relapsing febrile nodular panniculitis (Weber-Christian disease) review of literature and report of case *570
Benzoin Therapy See Dermatitis repens
Berkovsky, M Sarcoid, case for diagnosis 808
Berlin C Granuloma cutis calcinosum following injection of calcium levulinate *1204
Berman, L Multiple squamous cell carcinoma of skin associated with chronic lymphatic leukemia observations on effect of urethane therapy, *625
Bernstein, E T Kaposi's sarcoma coincidental with pigmented nevus 413
Beryllium granulomas of skin *1140
Besnier-Boeck's Disease See Sarcoidosis
Bile Ducts, pulsating hemangiomas, hepatic cirrhosis 875
severe generalized excoriations associated with jaundice (possible xanthomatous biliary cirrhosis), 904
Binkley, G W Lichen planus atrophicus chronic atrophic lichenoid dermatitis (Csillag) or retiform parapsoriasis 906
Birthmark See Nevi
Biskra Button See Leishmaniasis
Bismuth and Bismuth Compounds extensive pigmentary changes following bismuth therapy, 959
reactions to bismuth sodium triglycollamate (bistrimate®), *1206
Therapy See Lupus erythematosus, Skin, diseases, Verruca
Bistrimate® reactions to bismuth sodium triglycollamate, *1206
Therapy See Lupus erythematosus, Skin diseases
Bites See Insects
Blank, H Cutaneous diphtheria 819
Blastomycosis, 894 See also Coccidioidomycosis, Moniliasis
chromoblastomycosis (recurrence in case reported in Archives 43 62 [Jan.] 1941), 470
cutaneous, therapeutic result 893
Kaposi's idiopathic pigmented sarcoma or chromoblastomycosis, 469
of foot (North American), 1221
of skin, 945
or bromoderma, 882
squamous cell carcinoma of leg, blastomycosis? 944
systemic, 861
with pulmonary involvement, 819
Blennorrhagia See Keratosis blennorrhagica
Blood, calcinosis of foot and elbow with normal amounts of calcium and phosphatase in blood, 970
carotene, carotenemia, 1035
carotene, keratosis palmaris et plantaris associated with carotenemia or pityriasis rubra pilaris 1032
Diseases See Anemia, Leukemia
proteins, edema due to hypoproteinemia, 1024
Sugar, necrobiosis lipoidica without hyperglycemia, case for diagnosis, 465
Vessels See also Periarteritis, etc
vessels, erythema induratum or nodular vasculitis, 1218
vessels, nodular vasculitis, *294
Bloom, D Lymphatic leukemia following vaccination against smallpox, case for diagnosis, 923
Peculiar eruption of granuloma annulare, case for diagnosis, 924
Pityriasis rubra pilaris, 803
Poikiloderma atrophicans vasculare, case for diagnosis, 920
Poikiloderma vasculare atrophicans with histologic picture of mycosis fungoides, 842
Bluefarb S M Chronic discoid lupus erythematosus—persistent despite treatment for 34 years 891
Leprosy case for diagnosis 891
Mycosis fungoides or psoriasis 892
Secondary syphilis and granuloma inguinale (?) 902
Body Mind and Body See Mind
Boeck's Sarcoid See Sarcoidosis
Bolr D Scleroderma 1051

Boil See Furuncle
Jericho See Leishmaniasis
Bones See also under names of bones
atrophy, progeria (?) with erythema of hands and feet, partial alopecia, congenital coloboma and osteoporosis, 439
diseases, Albright's syndrome (fibrous dysplasia of bone, precocious puberty and cafe au lait spots), 875
eosinophilic granuloma of pituitary gland, lungs, bones of skull, and skin, 1007
Bonner, J Epidermolysis bullosa, 908

Harley A Haynes, M D, *President*

George W Binkley, M D, *Secretary*

March 27, 1947

Lymphogranuloma Venereum of the Shaft of the Penis, Nodules and Sinuses Presented by DR H H JOHNSON and DR A M TANNO (by invitation)

A Case for Diagnosis (Tuberculous Cervical Lymphadenitis? Lupus Miliaris Disseminatus? Tuberculid?) Presented by DR H H JOHNSON and DR A M TANNO (by invitation)

Pityriasis Rubra Pilaris? Presented by DR J KAM, DR R C LIGHT and DR A E WALKER (Service of DR H N COLE and DR J R DRIVER)

A Case for Diagnosis (Chronic Dissecting Cellulitis of the Groin and Left Foot Resembling Deep Mycosis?) Presented by DR J KAM, DR R C LIGHT and DR A E WALKER (Service of DR H N COLE and DR J R DRIVER)

Diffuse Progressive Scleroderma Presented by DR J KAM, DR R C LIGHT and DR A E WALKER (Service of DR H N COLE and DR J R DRIVER)

Perifolliculitis Abscedens et Suffoidiens Capitis (Hoffman) Presented by DR J KAM, DR R C LIGHT and DR A E WALKER (Service of DR H N COLE and DR J R DRIVER)

DISCUSSION

DR R C LIGHT There was pronounced improvement after the patient received two treatments of filtered roentgen rays

DR J R DRIVER I should like to ask whether any of the members have treated a condition of this kind with penicillin by injection and what the result has been

DR G H CURTIS I saw 2 patients in the Army treated with 8,000,000 units of penicillin without any benefit

DR H N COLE There were several of these patients at City Hospital, with chronic conditions They were given penicillin by injection and also treated locally with penicillin and penicillin irrigations, without any effect The disease in this case is relatively recent, which I believe is the explanation for the response

Severe Generalized Excoriations Associated with Jaundice (Possible Xanthomatous Biliary Cirrhosis) Presented by DR J KAM, DR R C LIGHT and DR A F WALKER (Service of DR H N COLE and DR J R DRIVER)

1 **Boeck's Sarcoid** 2 **Early Latent Syphilis, Partially Treated** Presented by DR J KAM, DR R C LIGHT and DR A E WALKER (Service of DR H N COLE and DR J R DRIVER)

A Case for Diagnosis (Dermatitis Repens?) Presented by DR H H JOHNSON and DR A M TANNO (by invitation)

Alopecia Liminaris Frontalis (Sabouraud) Presented by DR J KAM, DR R C LIGHT and DR A E WALKER (Service of DR H N COLE and DR J R DRIVER)

F W, a Negro woman aged 28, first noticed mild acne of the face and the gradual onset of alopecia of the frontal region of the head in October 1945 Within several months this reached its peak and has persisted to the present There is no history indicative of an endocrine disturbance She has used petrolatum on her hair for many years There is no family history of similar disease

Results of a general physical examination were normal, and she appears in good condition In the frontal portion of the scalp there is a symmetric, well defined band which is almost completely devoid of hair This extends from ear to ear and 3 to 5 cm back of the hair line There is conspicuous plugging of the follicles throughout, and the skin is slightly depressed, suggesting atrophy No erythema is seen There is mild papular acne of the face

Observations in hemograms and urinalyses were normal The result of the serologic test for syphilis was negative The basal metabolic rate was +16 per cent

On histologic examination, the epithelium showed no significant change There was a scattered infiltrate of lymphocytes, histiocytes and pigmented mononuclear cells in the upper part of the corium and to a lesser extent in a few deeper areas around the hair follicles Keratotic plugs often blocked the mouth of the follicles, which frequently contained no hair A trial course of 100,000 units of vitamin A daily for two months had no objective effect

DISCUSSION

DR H G MISKJIAN I have been interested in this subject for some years, after I read a long description of the syndrome given in the *Annales de dermatologie et de syphiligraphie* in 1931 by Sabouraud, in which he said that he had seen 12 cases of this disease in thirty years In the last ten or more years my co-workers and I have, here at the Lakeside Clinic, seen at least 10 or 12 cases, which were all in Negro women, and as far as I remember, all of them were in adults Sabouraud saw his cases in girls of acne age, about 15 to 18, and he mentioned a woman about 50 years old who had it, I have brought the book in which the picture of that woman appears This shows that there are differences between what Sabouraud reported and what we have seen here One of the differences is that in the syndrome we have seen the disease seems to be much more frequent than Sabouraud reported The second point of difference is that our cases are in adults and Sabouraud's were almost entirely in adolescents A third difference is in frequency, we have seen them much more frequently at our clinic The description seems to correspond closely with that of Sabouraud A patch of alopecia would develop on each preauricular temporal region, which would secondarily spread onto the forehead, toward the midline, with a band of alopecia about 1 inch (2 5 cm) or a little less Right on the fringe of the forehead and the band of alopecia there is usually a thin line of hair The patient presented today had that also The alopecia is supposed to be permanent, once it has been estab-

on legs with sickle cell anemia 1042

Mycosis—Continued
fungoides, (with vertebral involvement, treated with nitrogen mustard), 1215
superficial mycoses of veterans, dermatophytosis and cutaneous moniliasis, correlation of clinical manifestations and etiologic agent, *1120
Myoblastoma See Myoma
Myoma, leiomyoma, 850
leiomyoma cutis (zosteriform), 461
nonlipid granular cell tumors, *765
Myxedema and seborrheic dermatitis, 125
association of progressive (malignant) exophthalmos and localized myxedema, *318
circumscribed, of legs, 1044
extensive, circumscribed, 907
localized, pretibial, following thyroidectomy, 864

Nails, abnormalities, pachyonychia congenita (keratosis palmaris et plantaris, dystrophia unguium and leukoplakia oris), 846
case of keratosis follicularis with cutaneous, mucous membrane and nail changes, 902
dermatitis factitia, dystrophy of nails and keloids of palms and soles, 842
dermatitis herpetiformis (?) with mucous membrane involvement and nail changes, 971
dermatitis medicamentosa (atabrine), lichen planus, atrophy, scars, alopecia, pigmentation, nail changes, 447
diseases, dyskeratosis congenita with pigmentation, dystrophia unguium and leukoplakia oris, 853
diseases, idiopathic onycholysis, improved with thyroid and vitamin A therapy, 804
diseases, pachyonychia congenita (keratosis palmaris et plantaris, dystrophia unguium and leukoplakia oris), 846
leukonychia and hyperpigmentation of gums and lips, 921
onychomycosis, 471
tinea glabrosa, dermatophytosis, onychomycosis, pityriasis versicolor, erythrasma and tinea versicolor appearing in same patient, 811
trichophyton purpureum and monilia infection of hands, feet and nails, moniliasis of tongue, 822
Nares See Nose
Neck, pigmentation and atrophy of face and neck, lupus erythematosus (?), 1058
pseudoxanthoma elasticum of, with angioid streaks, 950
sarcoidosis (keloidal nesions on nape of neck), 909
senile elastosis of neck (pseudoxanthoma elasticum?) 802
solid edema of face and neck occurring in course of infectious eczematoid dermatitis, 1008
suboccipital dermatitis, *307
tuberculosis verrucosa cutis on, 829
Necrobiosis See Skin, diseases
Nelson, C T Kveim reaction in sarcoidosis, *377
Nelson, W E Xanthoma eruptivum secondary to lipid nephrosis, 828
Neoplasms See Cancer, Sarcoma
Neostigmine, Therapy See Scleroderma

Nerves See also Nervous System, Neuritis
cranial, paralysis of, complicating herpes zoster, *558
optic, progeria (?) with erythema of hands and feet, partial alopecia, congenital colomba and osteoporosis, 439
sensory, histologic changes in sensory nerves of skin in herpes zoster, *641
Nervous System See Nerves, etc
scleroderma or diabetes mellitus, syphilis of central nervous system, 1051
Syphilis See Neurosyphilis
Netherton, E W Parapsoriasis or erythrodermie congénitale ichthyosiforme, 908
Tuberculosis cutis, case for diagnosis, 908
Neurodermatitis, atopic eczema, congenital abnormalities, vascular nevus, elephantiasis, undescended testes, 1016
circumscripta of wrist, tinea of face (microsporum fulvum), 947
disseminated and circumscribed, treated with phenindamine (thephorin®), *390
lichen simplex chronicus of vulva of 3 years' duration in 7 year old white girl, 868
suboccipital dermatitis *307
with cataract and asthma 993
Neurofibromatosis, extensive nevus pilosus et pigmentosus (von Recklinghausen's disease?), 930
Neurofibromatosis—Continued
ichthyosis, 1017
multiple, 902
multiple, of von Recklinghausen, 902
or pityriasis rosea, 826
von Recklinghausen's disease, 891
von Recklinghausen's disease, case for diagnosis, 884
Neuroma, multiple neuromas of skin, 1037
Neuroses and Psychoneuroses, drug eruption, neurotic excoriations or cutaneous tuberculosis, 902
psychosomatic dermatitis or dermatitis herpetiformis, 828
role of emotion in disorders of the skin, *1063
therapy of psychosomatic dermatoses, *303
ulcer (posidesiccative, left thumb), xeroderma, acarophobia neurotic excoriations, 1012
Neurosyphilis See also Dementia Paralytica
juxta-articular nodes in patient with neurosyphilis, 817
pain in breast due to, *1203
treatment with penicillin combined with artificial fever, *513
widespread papulosquamous eruption, 998
Nevi See also Angioma
atopic eczema, congenital abnormalities vascular nevus, elephantiasis, undescended testes, 1016
concurrent melanosis and hypertrichosis in distribution of nevus unius lateris *135
cylindroma, nevus, papilliferus syringadenomatosus, or turban tumor, 811
extensive nevus pilosus et pigmentosus (von Recklinghausen's disease?), 930
fate of central nevus in leukoderma acquisitum centrifugum, *1160
hairy, of scalp, 1018
hypertrophic Darier's disease and nevus syringocystadenomatosus papilliferus, histopathologic study, *500
Kaposi's sarcoma coincidental with pigmented nevus, 143
leukoplakia, sublingual (white sponge nevus?), 867
lichen striatus, or nevus, 882
multiple, (adenoma sebaceum) (dermatosis papulosa nigra and fibroma pendulum) in Negro, 864
multiple pigmented, 818
nevus cerebriformis, 989
nevus comedonicus, 130
nevus pigmentosus et pilosus, 990
nevus linearis or linear lichen planus, 950
nevus unius lateris with chronic inflammation? 868
pigmented, diagnosis and treatment of, consideration of some of pitfalls, *14
pigmented nevus, melanosis oculi, 970
psoriasis, toxic eruption secondary to dermatophytosis, blue nevus, 1012
solid carbon dioxide as anesthetic in electrodesiccation of cutaneous blemishes, 797
Vascular See Angioma, Telangiectasia
verrucous lupus erythematosus or nevus verrucosus, 1041
Nevoxanthoendothelioma, 1044
case for diagnosis, 1044
Nevoxanthomaendothelioma, 1038
New, W N Leiomyoma cutis (zosteriform), 461
Newborn Infants See Infants, newborn
Newman, B A Mycosis fungoides (treated with nitrogen mustard), 1215
Mycosis fungoides (with vertebral involvement, treated with nitrogen mustard), 1215
Nicholas, L Keratoses of palms and soles (chronic) (caused by arsenic?), pigmentation (generalized) (caused by arsenic?), dermatitis (atopic) of hands, forearms, ankles and popliteal areas (chronic), cirrhosis (portal) of liver (chronic) (cause undetermined), 826
Localized amyloidosis cutis of legs, 461
Psoriasis, with extensive Koebner phenomenon induced by systemic reaction to sulfadiazine applied locally to burn, 822
Trichophyton purpureum and monilia infection of hands, feet and nails, moniliasis of tongue, 822
Nicolas-Favre Disease See Lymphogranuloma Venereum
Niedelman, M L Combined simple and cavernous angioma, 828
Extensive cavernous hemangioma successfully treated with solid carbon dioxide, 131
Exudative discoid and lichenoid chronic dermatitis (Sulzberger and Garbe)? 125
Multiple large keloids, 821
Paget's disease of breast, 461

Ulcers—Continued
on penis, cause undetermined, erythroplasia of Queyrat or intraepidermal epithelioma, 913
(postdesiccative, left thumb), xeroderma, acrophobia, neurotic excoriations, 1012
radiodermatitis with ulceration (successfully treated with radon ointment), 1217
sinuses, nodules and ulcers of buttocks, tuberculosis colliquativa or actinomycosis, 937
Topical See Leishmaniasis, etc
ulcus vulvae acutum or triple symptom complex of Behcet, 1026
Ultraviolet Rays, lupus erythematosus or erythema solare, 970
Underwood, G B Primary irritants and sensitizers used in fabrication of footwear, *649
Underwood, L I Pyoderma vegetans in association with chronic ulcerative colitis, *161
Upshaw, B Y Hereditary anhidrotic ectodermal dysplasia, clinical and pathologic study, *1170
Urticaria, chronic, due to intestinal organisms, "giardia lamblia", "cure" following treatment with quinacrine hydrochloride, 902
chronic, of 17 years' duration, 1219
haemorrhagica, leukemid or purpura urticans, 1060
papular, flea problem in California (flea bites and papular urticaria, differential diagnosis), *1181
papular, is lichen urticatus form of urticaria? *1167
papular, lichen urticatus caused by dog's fleas, 127
pigmentosa, 859, 1056, 1222
pimentosa, case in child, with mast cells in corium, 873
pigmentosa in adult, 1056
pigmentosa of recent origin in adult, with no mast cells in section, 873
pigmentosa or hydroa puerorum, 460
pigmentosa or pityriasis lichenoides chronica (Juliusberg) 125
psoriasis, granuloma annulare, 1016
role of emotion in disorders of skin, *1063
Usher-Senear Syndrome See Pemphigus
Utterbach, M Acrokeratosis verruciformis, 912
Congenital ichthyosiform erythoderma, persistent notochord, 910
Granuloma telangiectaticum, 911
Lymphangiectasis of vulva, secondary to probable tuberculous salpingitis, pulmonary tuberculosis, moderately advanced, 910
Morphea or lichen sclerosus et atrophicus 912
Multiple benign cystic epithelioma, alopecia areata, 912
Nonspecific dermatitis, associated with lymphoblastoma, 910
Psoriasis arthropathica, 912
Scleroderma, acrosclerosis, 913

Vaccination See Immunity, Smallpox
Vaccinia See Smallpox
Vagina, herpetic stomatitis and vaginitis (pemphigus?), 818
Vaginitis See Vagina
Van Meter, R H Nevus comedonicus, 130
Vasculitis, nodular, *284
Vehicles, evaluation of bacitracin in local treatment of pyogenic infections, *106
Venereal Diseases See Chancroid, Gonorrhea, Neurosyphilis, Syphilis etc
Vero, J Dermatitis medicamentosa (phenolphthalein) followed by pigmentary changes, 449
Melanoma of leg, multicentric and pigmented basal cell epithelioma, 970
Pemphigus erythematosus (Senear-Usher syndrome) treated with vitamin A erythroplasia of Queyrat, 964
Steatocystoma multiplex in Negro woman aged 23, 444
Verruca acuminata of penis simulating carcinoma, 444
epidermodysplasia verruciformis, 878
epidermodysplasia verruciformis, case for diagnosis, 816
follow-up report (on case of plantar warts) 827
oral bismuth therapy in dermatology, *196
plana of face treated by posthypnotic suggestion, 1222
plantaris extensive, verruca vulgaris 823
Tuberculosis See under Tuberculosis
Vertebrae See Spine
Veterans, superficial mycoses of, dermatophytosis and cutaneous moniliasis, correlation of clinical manifestations and etiologic agent, *1120
superficial mycoses of, survey of 1,000 veterans with service diagnosis of dermatomycosis, *712
Viruses, virus-pyogen sequence, interrelationship in inflammatory dermatoses clinical features, *261
Vitamins See also Ascorbic Acid
A, Darier's disease (keratosis follicularis), improvement following vitamin A therapy, 902
A, deficiency, parapsoriasis or dermatitis medicamentosa, 1060
A, idiopathic onycholysis, improved with thyroid and vitamin A therapy, 801
A, keratosis follicularis (Darier's disease), improvement after therapy with vitamin A, 915
A, keratosis follicularis (treated with vitamin A), 111
A, pemphigus erythematosus (Senear-Usher syndrome) treated with vitamin A, erythroplasia of Queyrat, 964
A, pityriasis rubra pilaris improved by treatment with, 165
A, pityriasis rubra pilaris uninfluenced by treatment with, 872
D, favorable response of tuberculosis cutis (lupus vulgaris) to therapy with vitamin D, 1049
D, lichenoid and miliary sarcoid (Boeck) in Negro woman improved after treatment with calciferol (vitamin D_2), 970
D, lupus miliaris disseminata faciei, improvement from treatment with vitamin D_2, 898
D, lupus vulgaris improved from treatment with calciferol (vitamin D_2), 970
D, lupus vulgaris, improved with calciferol therapy, 985
D, lupus vulgaris improved with vitamin D_2, 898
D, lupus vulgaris successfully treated with calciferol (vitamin D_2), 971
D, lupus vulgaris treated with calciferol, 985
D_2, treatment of lupus vulgaris with calciferol (vitamin D_2), *614
deficiency associated with ichthyosis, epidermolysis bullosa, spina bifida occulta 997
Vitiligo, fate of central nevus in leukoderma acquisitum centrifugum, *1160
with elevated border, 992
Vulva, lichen sclerosis et atrophicus, accompanied with bullous eruption involving vitiliginous areas of anus and vulva, 990
lichen sclerosus et atrophicus, inframammary inguinal and vulvar, 1038
lichen simplex chronicus of 3 years' duration in 7 year old white girl, 868
lymphangiectasis of, 882
lymphangiectasis of, secondary to probable tuberculosis salpingitis, pulmonary tuberculosis moderately advanced, 910
ulcus vulvae acutum of Lipschutz, case for diagnosis, 1020
ulcus vulvae acutum or triple symptom complex of Behcet, 1026

Walker, A E Acrodermatitis chronica atrophicans, 909
Alopecia liminaris frontalis (Sabouraud), 905

DR W R HUBLER I do not believe that she has pemphigus There are numerous, annular, bullous lesions on the face and shoulders The symmetric distribution of the eruption and the localization on the neck, axillas, elbows, knees and shoulders, as well as the grouping of the lesions, all point to a herpetiform type of eruption The patient is Rh negative, the husband Rh positive, and she is beginning to have anti-Rh antibodies About six months ago she was hospitalized by a gynecologist for what was apparently an early spontaneous abortion This would account for the early rise in anti-Rh titer I do not know what the Rh titer has to do with herpes gestationis, but I feel that some factor might be implicated since it usually clears with termination of pregnancy Therapeutic abortion should be performed in this case, because in a number of cases in which the patients were allowed to go to term, the percentage of monstrosities among living children was much higher than normal and stillbirths were common (Mueller, C *Am J Obst & Gynec* **48** 170-180 [Aug] 1944) Also, in some cases the herpetiform eruption persists after the completion of pregnancy when the patient is allowed to go to full term

NOTE—The follow-up examination of August 1947 showed that the eruption had subsided strikingly after a therapeutic abortion However, punctate, small vesicles persist in the groin and axillas, on the chin and in other scattered areas These are subsiding with inorganic arsenical therapy Hyperpigmentation has developed further showing the relationship to dermatitis herpetiformis The anti-Rh titer, three months after the therapeutic abortion, is only 1 1

Extensive Circumscribed Myxedema Presented by DR M J GIBANS, Akron, Ohio

H O , aged 56, was subjected to a subtotal thyroidectomy in February 1945 because of a toxic goiter Preoperatively the basal metabolic rate varied from +72 to +79 per cent, and the blood pressure was 154 systolic and 84 diastolic Postoperative examinations showed metabolic rates of +27 and +40 per cent, and finally —15 per cent, and the blood pressure was 130 systolic and 70 diastolic His weight, which had been 130 pounds (59 Kg) before operation, increased to 179 pounds (81 Kg) thereafter About four months after operation, the patient noticed a little discoloration and redness about the ankles This progressed slowly until some months later, after he had returned to work, when it extended rapidly This has never caused him any discomfort

He now has nonpitting, tawny, elevated, nodular plaques, with moderately enlarged follicular openings, on the anterior aspects of both legs These plaques are much more extensive on the right leg, involving almost the entire lower half and extending over the medial surface and posteriorly, where there is one unusually large and firm mass, about 2 inches (5 cm) in diameter

The microscopic description by Dr Lloyd Catron was as follows There are slightly increased deposits of melanin in the epidermis, with edema of the corium The hair follicles are dilated and plugged with keratohyaline material The small blood vessels are thick walled There is a patchy infiltrate, composed chiefly of lymphocytes, around accessory skin structures The histologic appearances are compatible with circumscribed myxedema The patient has recently been given thyroid extract, 2 grains (130 mg) daily

Bullous Eruption (Pemphigus) Presented by DR E GILLESPIE, Canton, Ohio

Acrodermatitis Chronica Atrophicans Presented by DR A E WALKER and DR W MARMELZAT (service of DR H N COLE and DR J R DRIVER)

Scleredema Adultorum (Buschke) Presented by DR A E WALKER and DR W MARMELZAT (service of DR H N COLE and DR J R DRIVER)

L S, a 51 year old Italian woman, had, approximately twenty months ago, a sudden onset of nonpruritic thickening and tightening of the skin of the neck, which spread to the lateral and anterior portions of the neck, the lateral aspects of the face, back, shoulders, upper arms and upper part of the chest The skin is softer now than it was after onset of the condition The patient has had previous episodes of infection of the upper part of the respiratory tract and influenza but no clearcut episode immediately preceding the onset of her present illness (There is a language barrier and a lucid history is difficult to obtain)

The patient has diabetes mellitus, which is being treated by diet and insulin She also has been treated medically for a hypertrophic arthritis Two years ago she had menorrhagia, the cause of which was never explained

There is painless, nonpruritic thickening of the skin of the back of the neck, extending over the dorsum to the iliac area, laterally around the neck to the anterior aspect, over the shoulders and upper arms to the deltoid area, and over the upper part of the chest and superior portion of both breasts The epidermis is not changed There is no pitting edema There are bilateral xanthelasma lesions

Urinalysis showed sugar (4 plus) and acetone (3 plus) The urea nitrogen was 18 mg per hundred cubic centimeters The fasting blood sugar was 303 mg per hundred cubic centimeters Total proteins were 6 3 Gm per hundred cubic centimeters—albumin 3 8 Gm and globulin 2 5 mg, combining power 52 5 milliequivalents per liter, blood cholesterol 354 mg, serum calcium 9 8 mg and serum phosphorus 4 3 mg per hundred cubic centimeters Results of hemocytologic studies were normal The blood and spinal fluid were normal The basal metabolic rate was +17 per cent Roentgenograms of the chest, sinuses, jaw and skull were normal

Biopsy of the skin revealed the epidermis to be normal The corium was thickened, made up of deeply acidophilic, greatly hypertrophied collagenous fibers The small vessels and capillaries were not remarkable but were surrounded by a moderate infiltration of lymphocytes and occasional polymophonuclear leukocytes No treatment has been given

DISCUSSION

DR H A BRUNSTING What is the duration of the disease?

DR R C LIGHT In the *New England Journal of Medicine* several months ago there was a report of a case of twenty years' duration

DR A E WALKER Another review I saw listed 1 case lasting thirty years and 1 four years The average is eight to eighteen months

Sarcoidosis (Granuloma Annulare [?] of the Elbows and Knees) Presented by DR A E WALKER and DR W MARMELZAT (service of DR H N COLE and DR J R DRIVER)

Penicillin was administered, with pronounced diminution of the secondary infection The patient was transferred to Sunny Acres, Cuyahoga County Tuberculosis Hospital, for treatment of her tuberculosis

A Case for Diagnosis (Granuloma Telangiectaticum?) Presented by DR M H GUSTAFSON, DR E H JONES JR and DR UTTERBACH (service of DR H R TRATTNER)

G S, a 50 year old man, was first seen on the urologic service in September 1947, with a complaint of numerous growths on the penis and the scrotum, of two years' duration The lesions started as a papule on the dorsum of the penis and gradually increased in number and size, finally involving the entire penis, the scrotum, the perineum and the perianal area The lesions have been asymptomatic

The patient gave a history of having had gonorrhea in 1929 A urethral stricture developed in 1932 In 1933 the first of a series of urinary fistulas appeared, and since that time numerous fistulas have developed around the base of the penis, the scrotum, the lower part of the abdomen and the perineum

The shaft of the penis, the scrotum, the perineum and the perianal area are covered with a fungating, polypoid mass The surface of the mass presents numerous flesh-colored nodules, pedunculated tumors ranging from a few millimeters to 3 cm in diameter Several fistulous openings may be identified in the crevices between the polyps Urethral strictures are present, preventing the passage of sounds

Results of urinalysis and the hemogram were normal The blood urea nitrogen was within normal limits The Kline and Wassermann reactions of the blood were negative Reactions to the Frei test and to skin tests for chancroid were negative An intravenous pyelogram revealed a normal right kidney and ureter, the left kidney was poorly visualized There was a slight hydroureter in the lower portion of the left ureter Suprapubic cystostomy revealed a normal bladder

Histologic examination showed stratified squamous epithelium, the seat of chronic inflammation, with fibrosis of the corium and areas of acute inflammation with focal ulceration

Treatment has consisted of the administration of penicillin and suprapubic cystostomy in preparation for plastic repair

DISCUSSION OF PRECEDING CASES

DR G A DEORDO I think that both of the preceding cases are manifestations of lymphostasis, associated with lymphatic blockage, in the woman due to tuberculosis and in the man resulting from obliteration of the lymphatics by some chronic inflammatory process associated with his gonorrheal infection Clinically at least, the growths looked like lymphangiomas, a form of elephantiasis Microscopically, the picture in the man looked considerably different There are many dilated capillaries or possibly lymphatics with thicker walls I should offer the diagnosis of elephantiasis or lymphangioma in both cases

DR F M MACDONALD I have never seen elephantiasis due to granuloma inguinale This is not the usual picture, but for the sake of work-up it is a very unusual situation I did not see any reference made to examination for possible Donovan bodies Perhaps that was done and I did not see mention of it on the report

DR J E RAUSCHKOLB The case of A S is a lymphostatic type of disorder, that contention is proved There are elevated little cystic lesions, and the lymphostasis probably arises from a chronic inflammatory pelvic condition, which we assume to be of a tuberculous origin

lished, and one is supposed to see in the bald area small cicatricial lesions, which I was not able to see in this case I think it would be a very worth while contribution to bring together all of these cases to study them and point out that this syndrome is perhaps more frequent in the Negroes than in white person Nothing is known about it, because Sabouraud seemed to think that the syndrome must be placed between what he calls staretoid baldness, in other words alopecia, and an acneform process, because in the early stages he was able to see acne lesions in areas which later became bald There is a good description of this syndrome in Dr Sutton's book, "Diseases of the Skin," which is accurate

DR J A GAMMEL A few months ago I had a Negro woman patient with what I called alopecia areata, limited to the same areas, which cleared up very well in three months

DR H G MISKJIAN When this patient first came to us we considered the diagnosis of alopecia areata, because the case was not so very characteristic, and we ruled it out at that time At the present time the appearance is not that of alopecia areata There are thin areas that one would ordinarily not see in alopecia areata

DR J A GAMMEL I do not want to make a diagnosis in this case, but merely comment that I saw one with the disease limited to these areas There was complete baldness for two weeks, and in three months the whole process was over

DR H H JOHNSON There is one thing that Negro women do that is peculiar to their race, and that is using various methods of attempting to straighten hair I believe that that should be investigated thoroughly to find out what methods they use to accomplish it

May 22, 1947

Herpes Gestationis Presented by DR W R HUBLER, Youngstown, Ohio

DISCUSSION

DR J E RAUSCHKOLB This patient has neither oral nor ocular lesions She is two or three months pregnant In spite of this eruption having followed the beginning of pregnancy, I believe that the case is one of pemphigus vegetans because of the extreme prostration and toxicity and the grouping of the bullae on the neck band and axillary and genital areas, which are beginning to pile up and vegetate

DR C G LA ROCCO I agree with Dr Rauschkolb

DR J R DRIVER I agree with the diagnosis as presented There was no Nickolsky sign The woman is pregnant and has had this eruption since her pregnancy started A therapeutic abortion is indicated

Histologic examination showed pronounced hyperkeratosis, unusual prominence of the stratum granulosum, acanthosis and superficial chronic perivascular inflammatory infiltration of the corium

Since follow-up antisyphilitic therapy was instituted with bismuth subsalicylate, the patient says that the lesions have regressed for the first time

DISCUSSION

DR M UTTERBACH This patient gave a history of similar lesions in other members of her family, which I think is significant It is difficult to evaluate the lesions themselves We considered diagnosis of acrokeratosis, hydrokeratosis and perhaps linear nevus Biopsy showed definite proliferation of the corium Therefore we thought of the possibility of an acrokeratosis

DR H A HAYNES JR I have never seen a case like this, but the disorder could be verruca plana, inasmuch as it is undergoing involution with therapy

DR H J PARKHURST I thought that clinically on close inspection these do not appear to be ordinary warts They resemble the lesions in a case which I previously saw of epidermodysplasia verruciformis

DR G W BINKLEY It would be interesting to get a progress note on this case

A Case for Diagnosis (Palmar and Plantar Keratoses [Arsenic?] [Keratoderma Disseminatum Palmaris et Plantaris]? Superficial Epitheliomas, Trunk Ulceration, Left Small Toe and Left Palm [Squamous Cell Epithelioma?]) Presented by DR B LEVINE, DR B PERSKY and DR I L SCHONBERG

A Case for Diagnosis (Ulcer, Penis, Cause Undetermined? Erythroplasia of Queyrat? Intraepidermal Epithelioma?) Presented by DR H H JOHNSON and DR I L SCHONBERG

J T, a Negro aged 32, was circumcised in February 1945, since which time there has been a superficial ulcer on the glans penis He has been hospitalized on numerous occasions since 1945 because of this penile lesion The treatment has included the administration of penicillin and numerous local medications, without any signs of improvement during this two year period

On admission to the service in May 1944 the patient was found to have a positive serologic reaction and was treated with a series of injections in the arm and the hip In 1945 he received 146 injections of penicillin because of the positive

Circumscribed Scleroderma Presented by DR F M MCDONALD, Akron, Ahio

Lichen Striatus Involving the Leg of a Four Year Old Girl Presented by DR F M MCDONALD, Akron, Ohio

Porokeratosis of Mibelli Presented by DR C L BASKIN, Akron, Ohio

T N, a 70 year old man, a native of Italy, came to the United States forty-five years ago His inability to understand the English language prevents a complete history in this case His general health has always been good, he has never lost time from work

The present eruption began when he was a small child, gradually spreading from a spot on the left calf to include the entire leg and a large area of the sole The lesions show the characteristic threadlike border and polycyclic configuration There has been a slow steady advance of the margins during these many years All laboratory examinations showed normal values

DISCUSSION

DR G W BINKLEY This is a giant form of porokeratosis of Mibelli In addition to the appearance of the lesion, the long duration and the patient's Italian nationality are points in favor of a diagnosis of porokeratosis of Mibelli There is a sharp border between the normal skin and the involved skin

DR. W R HUBLER I believe that vitamin A has been used in the treatment of porokeratosis of Mibelli with some success At the last meeting of the American Academy of Dermatology a patient with this disease was presented, and several dermatologists stated that they had noted improvement following administration of large doses of vitamin A

Keratosis Follicularis (Darier's Disease) Improvement After Therapy with Vitamin A Presented by DR E L GLICKSBERG

A Case for Diagnosis (Erythema Elevatum Diutinum? Eosinophilic Granuloma?) Presented by DR I L SCHONBERG

S F, a white man aged 62, first noted swellings on the head and the left arm in 1926 At that time he was treated with various methods, including roentgen irradiation and use of solid carbon dioxide After the application of the solid carbon dioxide an ulcerated area, which required many months to heal, developed on the scalp Since that time the patient has acquired new tumors on the left part of the chest and on the nose These have grown slowly and have darkened About three months ago several nodules were removed surgically from the left breast and the left arm The lesions have been asymptomatic

General physical examination showed essentially normal conditions On the front and the left side of the nose there are two nodules, one the size of a bean and the other the size of an almond The tumors are sharply demarcated, reddish brown and firm to palpation On the left arm there are two dollar-sized areas of atrophy, at the border of which there are pea-sized to bean-sized violaceous nodules There is an atrophic, circular scar, 6 cm in diameter, on the scalp

Treatment has consisted of irradiation with filtered roentgen rays, without results

The results of urinalysis were normal, as was the examination of the stools The hemogram revealed 5,200,000 red blood cells, 10,000 white cells, and 13 Gm of hemoglobin, with a differential count of 62 per cent polymorphonuclear cells, 38 per cent lymphocytes and no eosinophils Testing for allergic reactions gave negative results

A biopsy specimen taken from the wall of the chest showed in the dermis and underlying subcutaneous tissue a circumscribed nodule, measuring about 1 cm in long diameter The central portion of the nodule was composed of dense bundles of collagenous fibers, which were diffusely infiltrated by wandering cells Toward the periphery of the nodule the blood vessels were prominent and considerably increased in number and showed pronounced perivascular infiltration by wandering cells, among which eosinophils predominated The most characteristic changes appeared to be at the base of the lesion in the subcutaneous fat, with vessels thickened there, the media showed slight infiltration by eosinophils, and the regional stroma showed intense infiltration by wandering cells, among which eosinophils predominated

At one edge of the nodule in the dermis there were large bundles of smooth muscle, apparently hypertrophied smooth muscle of a tortuous artery The epidermis was thinner than average, and interpapillary projections were obliterated There was a moderate amount of brown granular pigment in the basal epithelial cells

A second biopsy specimen, taken from the arm, showed a similar picture, but with less advanced sclerosis of the central portion of the nodule than was seen in the material from the wall of the chest At the base of the lesion there was a thick-walled blood vessel In the lesion itself there are numerous blood vessels showing intense cellular infiltration of the vascular wall and perivascular tissue, in which eosinophils predominate

Section stained by the azocarmine method showed an increase in blue-stained fibrous tissue, especially in the lesion from the chest wall, and abundant red-stained smooth muscle bundles in the area, suggesting tortuous or aneurysmal blood vessels in the dermis

Monocytic Leukemia, Schilling Type, Nodular Cutaneous Lesions Presented by DR G M STROUD

A Case for Diagnosis (Melanosis? Poikiloderma of Civatte? Chloasma?) Presented by DR A E WALKER and DR W MARMELZAT (service of DR H N COLE and DR J R DRIVER)

Oct 23 1947

Congenital Ichthyosiform Erythroderma, Persistent Notochord Presented by DR M H GUSTAFSON, DR E H JONES JR and DR M UTTERBACH (service of DR J E RAUSCHKOLB and DR G A DEOREO)

Nonspecific Dermatitis, Associated with Lymphoblastoma Presented by DR M H GUSTAFSON, DR E H JONES JR and DR M UTTERBACH (service DR ROY W SCOTT)

Lymphangiectasis of Vulva, Secondary to Probable Tuberculous Salpingitis, Pulmonary Tuberculosis, Moderately Advanced Presented by DR M H GUSTAFSON, DR E H JONES JR and DR M UTTERBACH (service of DR J E RAUSCHKOLB and DR G A DEOREO)

A S, a 29 year old woman, was first seen on the dermatologic service in September 1947, complaining of pruritic lesions of the vulva, of four months' duration She said that they had gradually increased in size and that the pruritus had become much more pronounced in the previous three weeks, with some weeping of the lesions She noted that a watery material was obtained from the individual lesions if she pricked them with a needle

Both the labia majora and the labia minora are covered with acuminate, cystic lesions, which are slightly tender and moderately pruritic The lesions are tense and are filled with a thin, colorless fluid Large, nonpigmented, polypoid lesions surround the external anal orifice Numerous healed scars are present on the abdomen and thighs The anal sphincter admits the index finger only, with much pain The rectum, within the reach of the examining finger, exhibits no abnormalities Bronchovesicular breath sounds, with fine, post-tussic rales, are heard at the apex of the right lung

Reactions to a skin test with old tuberculin (1 100,000) were positive Those to the Frei test were negative The Kline and Wassermann reactions of the blood were negative Results of urinalysis and the hemogram were within normal limits The roentgenogram of the chest revealed moderately advanced pulmonary tuberculosis of the upper lobe of the right lung

Histologic examination showed that the papillary projections of the epithelium were elongated and that there were many clusters of lymphocytes and plasma cells scattered throughout the underlying stroma, especially about the capillaries Just beneath the epithelium there were many dilated lymphatic spaces

MANHATTAN DERMATOLOGIC SOCIETY

David Bloom, M D, *Chairman*

Wilbert Sachs, M D, *Secretary*

March 11, 1947

Erythroplasia of Queyrat Cured. Presented by Dr E W Abramowitz

W L is a white man aged 42, born in the United States, married, with one child He works as a supervisor at a paper manufacturing company

He first came under my observation on Sept 20, 1945 He presented weeping, erythematous patches on the glans penis and the shaft Around this area there were numerous areas of telangiectasia said to have followed roentgenologic therapy to the affected areas, with no apparent effect on the original lesions The duration of the eruption was three and one-half years

He failed to respond to ordinary topical remedies such as Aloe vera pulp and ointment, penicillin or various soothing applications prescribed by other dermatologists and by me I finally resorted to a proprietary preparation containing menthol, phenol, camphor, oil of cloves, oil of eucalyptus and lime water in a vanishing cream base of undisclosed formula Since this has been used, the eruption has healed and the patient has had no further trouble The telangiectasia has remained His wife has recently given birth to another child

DISCUSSION

Dr Jack Wolf I think that this is an interesting and important case We have seen patients who have been cured, at least temporarily, with radiation, the improvement extending over several years Spontaneous remissions also probably occur in the course of the disease Apparently we do not as yet have the complete picture of the rationale of treatment or of the cure of erythroplasia of Queyrat

Dr Perry M Sachs (by invitation) I should like to know the time relationship between the roentgen treatments and the local therapy

Dr George C Andrews I accept the diagnosis in this case, but I think that generally we have to be cautious about accepting the diagnosis of erythroplasia I have in mind a patient whom I saw about two years ago He had had a penile eruption for about two months It was diagnosed as erythroplasia after biopsy by Army physicians On questioning him I found that he had taken sulfadiazine a month or so before the eruption began I told him that I would not accept the diagnosis of erythroplasia and gave him a mild lotion to use, and the balanitis cleared up entirely without any other treatment It is possible that the sulfonamide drugs produce eruptions something like erythroplasia at times We do not know what causes erythroplasia It may come from different things in different persons, so what cures one may not necessarily cure another When carcinoma is definitely present, it is a different matter The whole subject is rather involved

Dr Nathan Sobel These are interesting cases, and the condition is sometimes difficult to diagnose, as Dr Andrews and others have said When we see

The case of G S is of a condition I have never seen before, however Clinically, this looks like the male counterpart of an esthiomene, in which there is a urinary passage in the perineal area There are thickening and chronic inflammatory changes in the rectum and exuberant fibrotic growths on the penis and the pubic area The condition has improved tremendously in the last months from simply a little plastic surgery and the use of penicillin to clear up the secondary infection The Frei test, skin tests for chancroid and serologic tests gave negative reactions We found no smear positive for fusiform bacilli of Vincent Unfortunately, the smear for Donovan bodies was not made because the case was not into our service, although we recommended that it be done The disorder has probably resulted from a long-standing gonorrhea in which there was a posterior stricture and a false passage which opened in the perineum, with extravasation of urine into the structures adjacent to it, chronic inflammation of the structures and secondary infection being produced The diagnosis of granuloma telangiectaticum pyogenicum probably was made because there was an infected granuloma, although clinically the tumor is not the pyogenic type

Psoriasis Arthropathica Presented by Dr M H Gustafson, Dr E H Jones Jr and Dr M Utterbach (service of Dr Roy W Scott)

Morphea or Lichen Sclerosus et Atrophicus(?) Presented by Dr M H Gustafson, Dr E H Jones Jr and Dr M Utterbach (service of Dr J E Rauschkolb and Dr G A DeOreo)

Multiple Benign Cystic Epithelioma, Alopecia Areata Presented by Dr M H Gustafson, Dr E H Jones Jr and Dr M Utterbach (service of Dr J E Rauschkolb and Dr G A DeOreo)

H D, a 44 year old woman, has four siblings, her mother and a sister have lesions similar to hers The patient has a daughter, aged 23, who is just beginning to exhibit similar lesions

Acrokeratosis Verruciformis Presented by Dr M H Gustafson, Dr E H Jones Jr and Dr M Utterbach (service of Dr J E Rauschkolb and Dr G A DeOreo)

W H, a 16 year old girl, was first seen in the dermatologic service in June 1947, with lesions on the hands and feet, which have been present since birth They have produced no symptoms and have not changed in size since puberty

The patient's aunt and father have had similar lesions since birth The patient was treated with penicillin therapy for secondary syphilis, ending Sept 19, 1947 She was hospitalized for acute and chronic pelvic inflammatory disease in 1946 She states that her parents are not related by blood

Over the proximal interphalangeal joints and the knuckles of both hands are multiple, firm, keratotic papules, measuring 2 to 8 mm in diameter Over the medial and lateral aspects of both palms and soles and the tendo achillis are multiple, small, discrete, firm papules

The roentgenogram of the chest showed normal conditions The results of urinalysis and the hemogram were normal The Kline and the Wassermann reactions of the blood were 4 plus, with a titer of 1 64

DISCUSSION

DR NATHAN SOBEL It is an excellent result

DR JACK WOLF I think that Dr Sachs is to be congratulated It is the first opportunity that we have had of seeing any of the patients whom he has been treating We must take cognizance of the fact that this is not the only case he has shown tonight in which he has obtained a good result but that he is reporting a series of 10 cases, all of which he has followed assiduously Dr Abramowitz' case, which was reported tonight, and the instances of spontaneous improvement that we have seen do not detract in any way from the excellent work which Dr Sachs has done It adds an excellent method of treatment for a disease with which we have had so much trouble

DR MAX SCHEER I wonder whether the patients whom we have seen in this country with the disease which we label erythroplasia are suffering from what the French call erythroplasia According to the French authors, it is not only a precancerosis but it is a cancerosis and it invariably ends with metastasis to the inguinal lymph nodes and death In fact, there have been reports of cases in which the first lesion was a malignant process of the lymph node, followed later on by the erythroplasia of the glans penis In view of the fact that all the French cases have resulted in cancer unless radical treatment was performed and in view of the fact that, according to Dr Sachs, cancer has not developed in a single one of our patients, I wonder whether we are dealing with the same disease or whether it is contact dermatitis or some other kind of dermatitis, as Dr Rosen has suggested

DR PERRY M SACHS (by invitation) Whether or not we are dealing with the erythroplasia described by Queyrat is of secondary import It is erythroplasia as seen and diagnosed by dermatologists in this country and a disease which has proved resistant to all forms of therapy short of heroic measures

DR DAVID BLOOM I should like to ask Dr Sachs how he came to think of this treatment?

DR JACK WOLF Regardless of whether or not we are dealing with the disease which the French authors described, it must be admitted that if Dr Sachs has had such excellent results in the type of disease we see and which we call erythroplasia it is an important contribution to the therapy of a troublesome and obstinate disease We should be able to decide in the near future whether it is the same disease as that described by Queyrat

DR GEORGE C ANDREWS I had 1 case of erythroplasia, clinically typical and diagnosed microscopically by Dr Machacek, in which epithelioma of the penis developed and the patient died of metastasis

DR GEORGE M LEWIS Dr Sachs has observed 10 cases, which is probably 9 more than Queyrat had Why should we necessarily perpetuate Queyrat's conception unless it is the same as ours? I would support Dr Sachs's opinion over that of any of the foreign observers His cases are those in which we are interested It may be a different disease from the one described abroad, but it is the one that we see Furthermore, I think his treatment has been effective, and until this time our treatment has been poor Dr Sachs deserves a great deal of credit, obviously, he has controlled his work and has tried a great many remedies It is not something he thought of last week—he has been at it for a long time I think it is good work, he has not found the cause, but that is not always essential There are many diseases in which treatment is effective although the cause is unknown

reactions to the serologic test for syphilis Numerous lumbar punctures have shown no abnormalities

His blood pressure is 154 systolic and 110 diastolic Examination of the genitalia reveals a 2 by 3 cm ulcer on the left side of the dorsal surface of the glans penis, extending down to the shaft The ulcer has a red, granulating base, partially covered by a thick, dry crust, and the edges of the ulcer are slightly thickened and rolled The lymph nodes are not remarkable

In June 1946 the reaction to the Kahn test was 4 plus, with 10 Kahn units, and reactions to the complement fixation test were negative, however, on two occasions in November the serologic reactions were negative Several urinalyses have shown a specific gravity from 1 010 to 1 022, and on several occasions there have been white blood cells with clumping Biopsy of the penile lesion showed acute inflammation of the skin, with ulceration and atypical hyperplasia of the epithelium An electrocardiogram showed an essentially normal record, with slight elevation of the S-T segment

A Frei test gave negative reactions, and no definite inclusion bodies were seen on the slide of the biopsy specimen The patient has concluded a course of streptomycin, consisting of 4 Gm a day for six days The only other medication has been warm saline compresses to the penile lesion On this therapy there has been definite healing at the periphery of the ulcer and the ulcer is now approximately 1 cm smaller in diameter

The following is the report of the microscopic examination "Examination revealed that the epithelium was ulcerated The ulcer was densely infiltrated with many lymphocytes and plasma cells Over the ulcer there were necrotic debris and many polymorphonuclear leukocytes There were islands of epithelial cells in which the nuclei were large and vesicular, and there were a few large, irregular, oval bodies, resembling somewhat a molluscum body Some of the epithelial cells showed metallic diversion The diagnosis was acute inflammation of the skin, with ulceration and atypical hyperplasia of the epithelium"

DISCUSSION

DR G A DEOREO I think that this man has granuloma inguinale The rapid improvement on treatment with a relatively short course of streptomycin also points toward this diagnosis It is true that there are certain findings in the biopsy which suggest pseudoepitheliomatous hyperplasia, but these changes are frequently seen in granuloma inguinale

DR J E RAUSCHKOLB The chronicity of the lesion, the lack of pain and the resistance of the disorder to ordinary antisyphilitic drugs point, as Dr DeOreo says, to pseudoepitheliomatous hyperplasia, but the condition is not neoplastic in character, and it cannot be anything else but granuloma inguinale One ought to be able to find Donovan bodies, however

DR H N COLE This is a very interesting case One hesitates to make two diagnoses if one will suffice I have seen sections from a large number of cases of granuloma inguinale, and I have seen several examples of pseudoepitheliomatous hyperplasia, but I have never observed anything like the condition this man presents, as seen in the section I do not see how one can avoid calling this disorder intraepithelial carcinoma as well as granuloma inguinale Of course, in Negroes one does not very often see epitheliomatous changes on the skin, but this section shows such a remarkable picture that I do not see how we can refuse to make that diagnosis It would be interesting to have another report on this patient later

region of the hypochondria and the under surfaces of the breasts showed a definite picture of poikiloderma, consisting of reticulated pigmentation, telangiectasia and atrophy There was decided wrinkling of the upper parts of the breasts and reticulated hyperpigmentation and atrophy in both axillas The lower part of the back, inner aspect of the upper extremities and back of the neck were scaly and erythematous The axillary lymph glands were enlarged The upper eyelids showed erythema and edema, which had been present for the past two months

Laboratory examinations, including urinalysis, serologic tests of the blood for syphilis and complete and differential blood counts, gave essentially normal results

Biopsies of material taken from the skin under the breast and from the thigh showed features of poikiloderma

DISCUSSION

Dr Nathan Sobel The patient definitely had poikiloderma in the areas over the lower part of the breasts and atrophy over extensive areas elsewhere, but I am puzzled by the hyperkeratosis of the palms and soles and do not believe that is often found in cases of poikiloderma

Dr E W Abramowitz I have the same difficulty in reconciling the hyperkeratosis of the palms and soles I do not recall having seen it in cases of poikiloderma It is a question whether some other disease should be considered or whether further observation is necessary before the case is labeled poikiloderma

Dr George C Andrews The case reminded me of the cases of dyspituitarism with poikiloderma-like changes, reported by Bruno Bloch I think that the woman has endocrine disease A basal metabolism test, roentgenograms of the sella turcica, an encephalogram and various other tests are indicated In many cases of Cushing's basophilism the disease is related not to the pituitary but to the adrenal glands, so this case should be studied from that angle I am wondering whether the hyperkeratosis of the soles could be related to localized myxedema in which there is a great deal of lymph stasis that produces verrucous changes

Dr E W Abramowitz Dr Andrews brought up a point which might still point to the pituitary The patient may have keratoderma climactericum

Dr Fred Wise I agree with those who believe that the eruption is caused by a polyglandular disturbance similar to Cushing's syndrome, in which almost invariably telangiectasia and pigmentation of the lower portion of the breasts are present Poikiloderma is merely a symptom, whereas poikiloderma vasculare atrophicans is a definite clinical entity, as described by Jacobi This patient has a poikilodermatous skin associated with polyglandular disturbances, but the condition should not be described as a case of Jacobi's disease because, as the name suggests, that has a variegated appearance It would be better to describe it under a name which at least suggests pituitary basophilism or Cushing's syndrome

Dr David Bloom I realize the difficulty in diagnosing this condition Besides the poikiloderma-like eruption and the scaly plaques, the patient shows extensive keratosis of the palms and soles, which would fit in with psoriasis or keratoderma climactericum One finds erythema of the eyelids in poikilodermatomyositis, but in this patient it developed only one month ago, late in the course of the disease I am inclined to agree with Dr Andrews and Dr Wise in regard to a thorough study of the patient in order to eliminate an endocrine condition such as Cushing's pituitary basophilism A definite diagnosis, of course, cannot be made at present

A Case for Diagnosis (Leukonychia and Hyperpigmentation of Gums and Lips) Presented by Dr E W Abramowitz

DISCUSSION

DR G H CURTIS Clinically, the disease looked like sarcoidosis

DR B LEVINE I saw this man some years ago, and I thought at that time that he had sarcoidosis Many other dermatologists have seen him since

DR G A DEORDO In the 2 cases of erythema elevatum diutinum that I have seen, the edges of the lesions were more perpendicular than they are in this case and the surface formed a plateau The color was not quite as intense as in this case, and the microscopic picture was considerably different from the one we see in this case I should like to suggest the possibility of Kaposi's hemorrhagic disease

DR B PERSKY I should not quite agree with the diagnosis of eosinophilic granuloma here because of the absence of large cells either in the skin or in the bone There were quite a few eosinophils, but I do not think they would add up to the number seen in eosinophilic granuloma I have had occasion to deal with a case of erythema elevatum diutinum, with the characteristic features This case showed ring-shaped lesions around the digits and around the joints, quite blue but not as deeply blue as the lesions in the present case The lesions here somewhat resembled granuloma in that they had a smooth surface and an annular configuration They did not show the picture of granuloma annulare histologically There is one other possibility which I should like to suggest I am not at all sure how accurate the history is I should like to suggest the possibility of periarteritis nodosa There were some vascular changes I think that more biopsies might reveal those features, and possibly further observation and a fuller history as to whether there were remissions or relapses might help

DR I L SCHONBERG When I saw this patient for the first time I was very confused, as you might expect, and on going over his history there were several things that I thought of I was hoping that when I made the biopsy the diagnosis would be sarcoid, but unfortunately it could not be made on the section However, there was a new lesion at the base of the left breast, and we also decided to take a border specimen from the lesion of the left arm On pathologic examination, the condition was reported as periarteritis nodosa I do not feel that the disorder falls in that class, at least clinically On reading the literature, I became more and more confused as to whether or not it fitted in with that diagnosis In the February 1947 issue of ARCHIVES, pages 155 to 201, there are three or four articles on erythema elevatum diutinum and eosinophilic granuloma The examination of the section did not reveal a picture fitting into the type of erythema elevatum diutinum as described by the first author, but observations did fit in with the picture described by Weidman He stated that erythema elevatum diutinum presents a polyarteritis with a cellular infiltrate He quoted an Italian dermatologist, who described a case almost identical with the one I have shown He described lesions on the extensor surface of the hands, the ears, the face and the buttocks According to some of the descriptions, many of these cases began in early life However, there was a group of cases in persons usually over 40 years of age, who presented similar lesions Two types were described the "Hutchinson type," or soft type, with soft plaques, and the "Bury type," with hard nodules which undergo a purplish discoloration There is also a third type, which resolves by itself It is rather difficult to classify this case, but I do feel that there are some indications that it fits into one group or the other

A Case for Diagnosis (Lymphatic Leukemia Following Vaccination Against Smallpox?) Presented by DR DAVID BLOOM

J H, a man aged 80, was referred to me in September 1947 by Dr H Wolf because of a tumor which had developed in the area of smallpox vaccination five months previously The patient also suffers from generalized pruritus

On the external aspect of the right arm there was a walnut-sized, erythematous, raised and indurated, globular tumor, firm in consistency and with borders infiltrating the surrounding skin in an ill defined manner In the vicinity of the tumor there were a number of erythematous, pea-sized and excoriated papules In addition to this lesion which caused severe pruritus, there were excoriated lesions on the forearms, the lumbosacral region and the legs In the axillas slightly enlarged nodes were palpable

Biopsy of the tumor on the arm revealed a "nonspecific type of granuloma" A blood count on two occasions showed a normal red cell count, but a white cell count of 13,600 on one occasion and 16,900 on another The differential count, in addition to 3 per cent blasts, showed 58 per cent lymphocytes and 35 per cent polymorphonuclear leukocytes and on another occasion 76 per cent lymphocytes

The patient is in good general health except for the generalized pruritus which disturbs his sleep The lesion on the right arm has diminished in size after several treatments with filtered roentgen rays

DISCUSSION

DR WILBERT SACHS The microscopic section that I examined was from the arm and suggested a nonspecific granuloma The characteristic picture of lymphatic leukemia, which undoubtedly should be present in a lesion of this size, was not seen If the patient has lymphatic leukemia, it is unrelated to the lesion on the arm

DR SAMUEL M PECK A number of years ago I thought that it would be interesting to take cases of chronic lymphatic leukemia, acute leukemia and diseases like purpura hemorrhagica and do trichophytin, tuberculin and venom tests and study the histologic appearance, to see how a known blood picture would influence a histologic reaction with which I was familiar I found nothing very striking

DR WILBERT SACHS Instead of a leukemia infiltration, one finds a leukemid type of reaction, and this is nonspecific

DR ANTHONY C CIPOLLARO Does the patient have leukemia in the first place, and did vaccination have anything to do with it if he has? There has not been enough evidence to indicate a relation between smallpox vaccination and leukemia

DR DAVID BLOOM The diagnosis of leukemia was suggested by the increase in the white blood cells, the high lymphocyte count and the presence of blasts This opinion was shared by the hematologist, who advised sternal puncture In spite of the absence of a confirmatory histologic report, this diagnosis is most probably correct

Acrodermatitis Pustulosa Perstans Presented by DR WILBERT SACHS

Lymphoblastoma, Clinically Poikiloderma, Histologically Mycosis Fungoides Presented by DR JACK WOLF

a patient apparently cured, we are inclined to question the diagnosis I think we must accept the fact that this patient has had erythroplasia and try to give credit where it is due

DR E W ABRAMOWITZ I am sure that Dr Sachs will bring out other important features of this disease Erythroplasia was always considered a serious disease, a precancerosis Radical measures, even including amputation, were discussed I do not recall ever seeing a patient with erythroplasia of the penis in whom cancer of the penis developed I have wondered, therefore, whether radical measures were justified In this case, roentgen rays apparently had no effect except to produce telangiectasia I tried to treat this telangiectasia because in the beginning it seemed to bother the patient He was able to tolerate mild applications of solid carbon dioxide to the telangiectatic area I soon stopped that, however, and used mild boric acid ointment and solution, Aloe vera pulp and then ointment, with little improvement *It was not until Dr Cipollaro showed* a patient with erythroplasia who had responded to this proprietary preparation that I told my patient about it and suggested its use The patient reported immediate relief I think one can say now that this lesion is healed There has been no activity for several months

I should like to mention another patient, brought to me by a urologist who was considering the possibility of radical measures, there was an erosive lesion of the penis which he thought was cancer I thought it was a drug eruption, as the lesion was typical of a fixed eruption I questioned the man about phenolphthalein, and he denied taking it I was so convinced that he was lying that I went to his house and found feen-a-mint® (laxative containing phenolphthalein) packages and wrappers When he stopped using this the ulcerations disappeared It is not unusual to see lesions in the mouth and on the penis from phenolphthalein, and I have seen a fixed eruption on the penis and in the mouth from veronal® (barbital U S P) and other barbiturates

Erythroplasia—Cured Presented by DR WILBERT SACHS

E G K, a white man aged 45, first noticed a small red papule on the glans penis two and one-half years ago This grew until almost the entire glans was involved There was continuous oozing and slight itching The patient had been treated by several competent dermatologists, all of whom had made a diagnosis of erythroplasia Therapy consisted of local applications of various preparations and the use of roentgen rays, radium and hormone injections, with little or no results

Laboratory examinations, including blood counts, urinalysis and serologic tests, revealed no significant findings Microscopic examination confirmed the diagnosis of erythroplasia

When first seen by us in December 1946, the patient had an erythematous, shiny, oozing patch over most of the glans penis There was no scaling or crusting and no induration The following medication was applied locally, twice a week, for three weeks 0 3 Gm of neoarsphenamine dissolved in 4 cc of distilled water, to which 1 cc of glycerin is added

Oozing and all subjective symptoms disappeared within one week The lesion became crusted, and in the following few weeks the entire process disappeared, leaving no sequelae

DR WILBERT SACHS I should consider other possibilities in preference to granuloma annulare Before accepting this diagnosis, I should like to study the microscopic sections Although numerous giant cells may be found as a rule they are not a feature of granuloma annulare

DISCUSSION

DR THOMAS N GRAHAM I think that the individual papules on the dorsum of the right hand look like the lesions usually observed in granuloma annulare, although they are not in annular formation However, the lesions on the forearm do not resemble that dermatosis clinically but, rather, suggest lichen planus

DR FRANK E CORMIA (by invitation) Dr Peck and I had the same opinion—that, clinically at least, the lesions are suggestive of amyloidosis

DR SAMUEL M PECK What struck me was the two distinct types of lesions The first was the skin-colored lesions on the back of the hands and even on the elbows which I should not hesitate to call granuloma annulare Then I saw another type, peculiar brownish-bluish lesions which made me think of amyloid disease but the fact that the microscopic appearance of three lesions was the same makes me doubt that we are dealing with amyloidosis The peculiar cases shown at the meeting of the American Academy of Dermatology and Syphilology in Chicago turned out to be extracellular cholesterosis I should certainly like to see studies made along that line

DR ISADORE ROSEN The clinical features suggest the lichenoid type of sarcoid rather than granuloma annulare

DR NATHAN SOBEL One of the thoughts that first occurred to me was possible amyloidosis, but against that is the complete absence of itching, which is certainly a distinctive feature of amyloidosis The lesions around the anterior surface of the wrist are skin colored and hard and could fit into the picture of granuloma annulare The other lesions are not characteristic and look almost like lichen planus at a casual glance I think it best to include all the lesions as granuloma annulare

DR MAURICE J COSTELLO This case impressed me also as one of lichenoid sarcoid I should like to see the results of tuberculin tests and roentgen examination of the chest I think that it is true that granuloma annulare responds to roentgen rays

DR DAVID BLOOM The biopsy report was surprising to all of us who had observed this case and did not think of the diagnosis of granuloma annulare Although I have seen atypical cases on several occasions, particularly of disseminated granuloma annulare in children, I have never seen a case similar to this one The patient will be studied more thoroughly

Darier's Disease Presented by DR NATHAN SOBEL

A Case for Diagnosis (Keratoses? Lupus Erythematosus?) Presented by DR ANTHONY C CIPOLLARO

Mycosis Fungoides Presented by DR MAX SCHEER

Parapsoriasis Guttata Presented by DR MAX SCHEER

Hypersensitivity to Cinnabar in a Tattoo Presented by DR JACK WOLF

Multiple Superficial Basal Cell Epithelioma with Arsenical Keratoses Presented by DR JACK WOLF

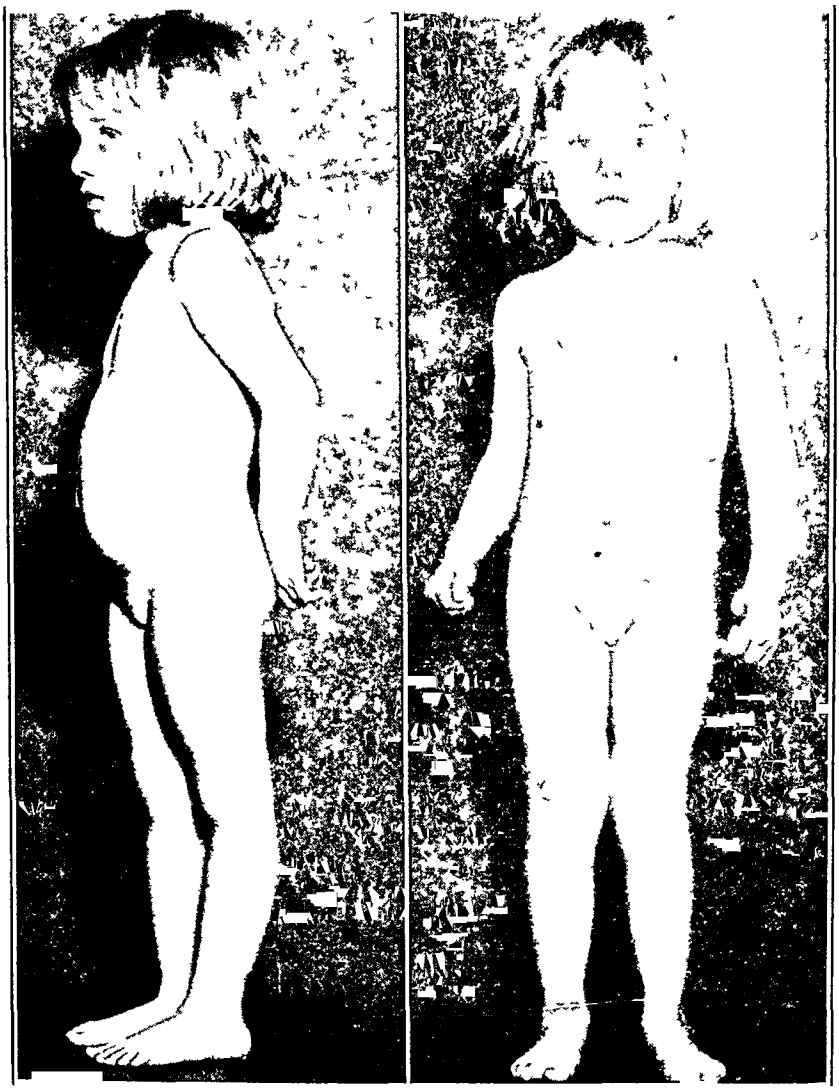
DR JACK WOLF Dr Sachs says that his therapy produces an adherent crust which remains for a long time Does he think, then, that we can achieve more rapidly the same type of crust and destruction by desiccation with the high frequency current or by the use of acids such as trichloroacetic acid? Is there any essential difference?

DR FRED WISE I am in complete accord with what Dr Lewis has said, but I think it would be not only desirable but necessary for the author to state that he is not sure he is dealing with the identical disease described by Queyrat American readers regard the term erythroplasia as meaning erythroplasia of Queyrat, and I suggest a notation to the effect that Dr Sachs is not sure he is dealing with that entity but that he is dealing with a disease similar in appearance and in chronicity, which, however, does not eventuate in cancer

DR DAVID BLOOM Neoarsphenamine dissolved in distilled water and then in glycerin, in 10 per cent concentration, has been used for several decades in the treatment of Vincent's infection of the mouth It is logical to assume that the beneficial effect obtained by Dr Sachs in his cases of erythroplasia is due to the effect on spirochetes or bacteria In these cases, therefore, there should be bacteriologic examination, irrespective of their duration

DR GEORGE M LEWIS I wonder if some of the malignant processes that supervene in these cases are the result of the treatment administered, such as desiccation or the use of pastes and irritant remedies In your opinion, Dr Sachs, is treatment ever responsible for malignant changes?

DR WILBERT SACHS The disease treated in this case, and in the other 9 cases reported in our paper, is the same as that described by Queyrat The French authors believe that in most of the cases the lesions become malignant The experience in our cases is not in accord with this view There have been only 2 cases reported in the American literature in which malignant changes developed In 1 the original diagnosis was questioned, in the other, the lesion was basal cell epithelioma and not erythroplasia Dr Andrews' case would make a third There are cases in which the lesion has all the clinical features of erythroplasia but microscopically proves to be either basal cell epithelioma or Bowen's disease However, as Dr Lewis suggests, it is always possible for a malignant process to follow long-continued treatment which includes such heroic measures as those employed in an endeavor to control erythroplasia In reply to Dr Wolf's question, desiccation and escharotic preparations have produced good results in some cases, but with sequelae and disfigurement These have not followed the treatment we are reporting



A Case for Diagnosis (Poikiloderma Atrophicans Vasculare?) Presented by DR DAVID BLOOM

R C, a white woman aged 47, complained of an eruption on the palms and soles of eight months' duration and of a generalized eruption of five months' duration The family history and the past history was essentially irrelevant The patient seems to be in fairly good general health

The plantar surfaces of the feet, and particularly of the heels, showed pronounced hyperkeratosis The dorsal surfaces of the feet and toes were slightly scaly and mildly erythematous The palms were dry and scaly and showed accentuation of the natural lines The backs of the hands and fingers were similarly affected, but to a lower degree The anterior and lateral aspects of the thighs and hips showed erythema, scaling, wrinkling and mottled hyperpigmentation The

DR JOHN G DOWNING I rubbed my finger nail on the leg After a few minutes a wheal appeared I think that it is a case of urticaria pigmentosa Whether this lesion belongs to the nevoid group, I do not know, other cases of urticaria pigmentosa are so classified

DR BERNARD APPEL, Lynn, Mass The histologic examination should have revealed a typical infiltrate if this were urticaria pigmentosa

Pigmented lesions in a 4 year old girl

Multiple Epidermal Cysts of the Skin Presented by DR MAURICE M TOLMAN, Boston

A 29 year old white nurse, S C, is presented with lesions on the back of her hands of six months' duration She first noted dermatitis venenata on the knuckles of both hands from handling a patient's flowers This was an acute vesicular eruption which healed with mild therapy but left behind small white nodular lesions Four months ago she received roentgen therapy, 500 r in divided doses This caused increased redness and tenderness, there was no improvement in the nodular lesions In the last few weeks they have become somewhat less prominent without further therapy

Generalized Progressive Scleroderma and Dermatomyositis Improved with Diphenhydramine (Benadryl®) Presented by DR MAURICE J COSTELLO

J F, a married woman aged 42, was presented before this Society on Oct 10, 1944, with a generalized progressive scleroderma and dermatomyositis associated with acrosclerosis and Raynaud's phenomenon

Since March 1946 she has been given 400 mg of diphenhydramine daily, with remarkable improvement, there is increased mobility of the joints and softening of the boardlike infiltrations and the dyspnea, wheezing, dysphagia and loss of muscle power have been relieved to a remarkable extent The results have been so spectacular that the only abnormality remaining is the irreversible contraction of the fourth and fifth fingers

DISCUSSION

DR DAVID BLOOM I believe that diphenhydramine in such large doses should be given to a patient only when he is hospitalized and under close observation I saw a patient who had received 150 mg of the drug daily over a period of several weeks suddenly collapse with a sensation of constriction in the chest and numbness of the upper extremities

DR MAURICE J COSTELLO The patient's condition was so advanced that she had not only severe edematous thickening of the skin and lack of mobility of the joints but also dysphagia and dyspnea Her general practitioner gave her diphenhydramine mainly to relieve what he considered asthmatic symptoms, and she has taken 400 mg every day for a year and a half I presented this patient before this society in 1944, and the change since has been nothing short of remarkable This patient had received dihydrotachysterol (hytacherol®) with no benefit

DR SAMUEL M PECK When dihydrotachysterol works, it is only on the edematous part If diphenhydramine works, it is something entirely different I think that I shall try iontophoresis with pyribenzamine,® as I am doing with neurodermatitis, especially of the hands I know that the drug stays in the tissues for weeks

DR ANTHONY C CIPOLLARO Does diphenhydramine produce vasodilatation?

DR MAURICE J COSTELLO I believe so, because the patient has been free of the blanching of the fingers associated with Raynaud's phenomena I might add that the only other case I have seen recently that approaches this in therapeutic result was that of a patient whom I sent from Lenox Hill Hospital to Bellevue Hospital, who received a high protein diet with large doses of a protein hydrolysate (amigen®) Graphic studies were taken of the improved mobility of the joints and the skin overlying them

DR SAMUEL M PECK Was there a reversal of result with primary lesions again with a violet ring?

DR MAURICE J COSTELLO No I have never seen improvement from dihydrotachysterol that was permanent The diphenhydramine was discontinued in this case for three weeks, with recurrence of symptoms

eruption until the oil that caused the dermatitis was carried by the effervescent soda water to her face Wiley Sams (ARCH DERMAT & SYPH **44** 571, 1941) reported a case of dermatitis based on the photodynamic action of lime oil

DR JOHN G DOWNING This patient has used nose drops which may have contained silver nitrate Silver nitrate is precipitated rapidly by sun I have seen cases in Florida similar to these after exposure to the sun

DR JOSEPH GOODMAN The patient used a silver salt eighteen years ago for gonorrhea

DR WALTER F LEVER The histologic sections show no evidence of argyria If the pronounced darkening of this patient's skin were due to argyria, one should be able to see silver granules in the sections even without resort to dark field illumination There is considerable increase of melanin in the basal layer and an abundance of melanin-laden chromatophores in the upper part of the corium I regard this case, from the histologic point of view, as one of hyperpigmentation

DR JOHN G DOWNING These patients always exhibit pronounced pigmentation if they are exposed to excessive sunlight Argyria will increase this tendency

DR WILLIAM R HILL I was not impressed with the possibility of argyria, although I did not examine the patient's nails and conjunctivas I agree with Dr Lever histologically, there was too much pigment to suggest argyria Such pigment is found around the sweat glands

DR BERNARD APPEL, Lynn, Mass I was impressed not only by the streak across the forehead that resembled hat band dermatitis but also by the discoloration of the face and neck Melanosis of Riehl should be considered In questioning this man about his diet, I found that he practically never ate any fresh vegetables or fruits I think that there is a possibility of this being the dietary deficiency type of pigmentation which Riehl originally described This is also consistent with the microscopic picture

DR G MARSHALL CRAWFORD By common usage, I think that the term Berlock dermatitis has come to represent almost any bizarre pigmentary deposit caused by photosensitizing agents on the skin It is difficult to see how such a sharply defined rectangular patch could be created without a pattern contact such as a hat band The dye therein, or tanning chemicals, might be incriminated

A Case for Diagnosis (Bacterid?) Presented by DR JOSEPH GOODMAN, Boston

Mycosis Fungoides in a 56 Year Old Woman Presented by DR MAURICE M TOLMAN, Boston

Mycosis Fungoides in a 46 Year Old Man Presented by DR MILDRED L RYAN, Brockton, Mass

DISCUSSION OF CASES OF MYCOSIS FUNGOIDES

DR MAURICE J STRAUSS, New Haven, Conn The woman has changes on her tongue Dr McCarthy pointed them out and said that they were lesions of mycosis fungoides, he had seen a similar case I have never before observed this and wonder whether it would be possible to have a biopsy done to prove it

DR FRANCIS P MCCARTHY Textbooks on dermatology and oral medicine show plates of tongue lesions in mycosis fungoides About twenty years ago I saw a tongue which presented lesions of mycosis fungoides, somewhat like those on this woman's tongue The lesions were raised and nodular, the largest was 0 5 by

A Case for Diagnosis (Lichen Planus? Psoriasis?) Presented by DR NATHAN SOBEL

G F, a woman aged 52, was first seen at the Skin and Cancer Unit of the New York Post-Graduate Medical School and Hospital on Oct 16, 1947 with an eruption of six weeks' duration

On the right upper eyelid there is a well defined, oval plaque which shows an erythematous, raised border and depressed, crusted center On the buccal mucosa there are divided plaques with reddish borders The entire scalp shows thickening of the skin, erythema and scaling There are erythematous, superficial, slightly scaly, well defined round plaques on the chest and on the upper part of the back and arms on the left On the extensor aspect of the thighs and inner aspect of the right thigh there are some purplish lichenified plaques There are erythema and fissuring in the genitocrural creases All the finger nails show onycholysis The nails of both big toes are greatly discolored, thickened and loose

The only laboratory report available to date is on the Wassermann reaction of the blood, which was negative

DISCUSSION

DR DAVID BLOOM The patient presents lesions on the lower extremities and on the buccal mucosa which look like lichen planus and an eruption of the scalp and changes in the nails suggesting psoriasis This combination of psoriasis and lichen planus has been reported on several occasions

DR NATHAN SOBEL I think that the lesion on the left buccal mucosa is probably a bullous lesion of lichen planus I have also previously seen lichen planus on the scalp To settle the question, biopsy would be necessary I think the changes in the nails are psoriatic

NOTE—It was reported at the succeeding meeting, in November, that biopsies, one from the leg and another from the neck adjacent to the scalp, both showed mycosis fungoides

A Case for Diagnosis (Peculiar Eruption of Granuloma Annulare?) Presented by DR DAVID BLOOM

M McH, a woman aged 41, registered at the Skin and Cancer Unit of the New York Post-Graduate Medical School and Hospital in October 1947, complaining of an eruption of one year's duration The eruption started first on the elbows, later it appeared on the lower extremities, and in the past three months it has involved the wrists There are no subjective symptoms

On the posterior and internal aspects of both lower extremities, extending as far as the middle of the legs, there is a profuse eruption of bluish-brownish, flat lesions, from the size of a lentil to that of a pea, some of which feel somewhat infiltrated A similar but less profuse eruption is seen on the flexor and internal aspects of both upper extremities Over both knees and elbows there are pink to skin-colored, raised, indurated papules Similar lesions are seen over the external malleolus of the left leg There are a moderate number of raised, dark red, firm, globular and elongated lesions on the flexor aspect of both wrists, extending to the forearm Over the sacrum, similar lesions form an irregularly shaped plaque

Microscopic examination of lesions from the wrist, elbow and thigh all showed the structure of granuloma annulare As reported by Dr Charles F Sims, the epidermis was thin, and the corium beneath showed basophilic degeneration In the upper and middle parts of the cutis were areas of granular degeneration surrounded by small, round and wandering connective tissue cells, epithelioid and giant cells The infiltrate took an arciform arrangement in many areas

noted these lesions on both her thighs and her legs Those on the thighs have gradually cleared, but lesions have persisted on the calves She stated that she bruises too easily but gives no history of epistaxis It was stated that some lesions bled on several occasions following minor trauma This woman was extremely nervous and suffered from melancholia during her only pregnancy five years ago, she has taken sedatives at night since that time There has been considerable menstrual irregularity The general medical history was otherwise noncontributory There was no history of similar lesions or of epistaxis in the family

Examination revealed a profusion of dilated blood vessels restricted to the lower third of each calf Most of these are of telangiectatic caliber but some are slightly larger They gradually fade out on the middle portion of the calves and on the sides of the legs

The prothrombin time (clotting time) of the blood plasma was found to be 20 seconds The sedimentation rate of the blood was 3 mm in 1 hour The cellular elements of the blood were normal A specimen removed for histologic examination revealed only atrophy of the epidermis and fibrosis of the corium One small area was treated by electrodesiccation with some resultant diminution in telangiectasia

DISCUSSION

DR WALTER F LEVER This disorder is really not too rare It was first described in the American literature by Stokes (*Am J M Sc* **149** 669, 1915) under the name of generalized telangiectasia and was thought to be associated with syphilis Among subsequently reported cases some patients had syphilis, but in most instances they did not It was also found that the disorder was not necessarily generalized, in patients with localized distribution the lower legs are most commonly affected The telangiectatic vessels are dilated venules They are dilated because their innervation is defunct Recently, in a patient with telangiectasia of the lower legs, I injected both a vasoconstricting and a vasodilatory drug intradermally, following Perutz' directions (*Arch f Dermat u Syph* **148** 313, 1924-1925) Intradermal injection of 0 1 cc of a 10 per cent solution of caffeine sodium benzoate caused the skin around the site of injection to become bright red, but the affected vessels did not change their size Similarly, 0 1 cc of a 1 1,000,000 solution of epinephrine injected intradermally caused blanching of the skin around the site of injection, but did not affect the telangiectatic vessels The disorder is harmless as such, but it is advisable to examine such patients for syphilis

Boston, Feb 12, 1947

Incontinentia Pigmenti Presented by DR G MARSHALL CRAWFORD, Boston, and DR C R DAMIANI, Worcester, Mass

A 4 year old white girl of American birth, P W, is presented with an eruption on the trunk and upper part of the thighs present since early infancy At about the age of 3 months, pigmented streaks were seen on the back of the upper part of the thighs These gradually became more pronounced and extended upward, eventually involving the back and abdomen A year ago, when the patient had measles, the pigmented areas were observed to become scarlet, after recovery the areas gradually returned to the previous shade of brown No other member of the family has been affected by any similar condition There was no history of congenital anomalies, the child had a normal developmental history and was mentally alert

Examination reveals a pigmentary disturbance approximating the "bathing suit" distribution The upper limits are the xiphoid level anteriorly, the axillas laterally and the inferior edges of the scapulas on the back It extends downward over the trunk and across the hips and buttocks to about the junction of the upper and middle thirds of the thighs The lesions consist of symmetrically arranged striate and whorl-like pigmentary deposits of medium brown The majority of them are linear, and their length varies from 1 to 3 cm, most lesions are from 3 to 5 mm in width They are arranged in parallel fashion corresponding roughly to the cleavage lines of the metameric segments

A biopsy was performed, and histologic observations were reported as "consistent with lentigo"

DISCUSSION

DR WALTER F LEVER The histologic picture bears out the diagnosis of incontinentia pigmenti Considerable amounts of melanin were present in the upper part of the corium, whereas melanin in the basal layer was not increased Other forms of hyperpigmentation usually show increased pigmentation both in the basal layer and in the upper part of the corium

DR WILLIAM R HILL I think that Sulzberger and Bloch reported a case of incontinentia pigmenti and concluded that it was a familial disorder This case is not familial

DR WALTER F LEVER In several of the reported cases other abnormalities, such as ectodermal defects, were present in the patient as well as in members of the patient's family There is, however, only one report, that of Naegeli (cited by Sulzberger, M B, ARCH DERMAT & SYPH **38** 57, 1938), concerning the familial occurrence of incontinentia pigmenti Thus, the absence of a familial history is not against incontinentia pigmenti

DR WALTER F LEVER, Boston That would not explain the lesions on the forehead and scalp I agree with the presenter's diagnosis of dermatitis herpetiformis and would suggest that sulfapyridine be given in larger amounts I have observed a case in which there was no response until 6 Gm a day were given The patient has been taking that dose for six months, and it controls the eruption

DR JOSEPH GOODMAN, Boston What blood level of sulfapyridine was reached with that amount?

DR WALTER F LEVER, Boston I have done no determinations of the blood level

DR WILLIAM P BOARDMAN, Boston The patient told me that she was just as uncomfortable while taking sulfapyridine If the sulfonamide drugs are not well tolerated or are ineffective, why not try potassium arsenite solution (Fowler's solution) which has long been known to be effective in dermatitis herpetiformis?

DR JOSEPH GOODMAN, Boston The use of sulfapyridine in dermatitis herpetiformis interested me in relation to a patient I treated recently, starting as Dr Lever did and increasing to a maximum dose of 6 Gm a day My patient had typical dermatitis herpetiformis The drug was given in gradually increasing amounts over a period of three months At the end of that time she took 6 Gm daily for two and one-half weeks The blood level was slightly over 7 mg per hundred cubic centimeters, an adequate level of sulfapyridine The dermatitis did not improve more than 20 per cent It was a question whether 8 Gm a day would be effective The blood level seemed adequate, and I was a little uneasy about the situation as it was I wonder how many failures with sulfapyridine have been seen by the members of this society, with doses of 3 to 5 Gm daily as a maximum

DR OSCAR GILJE, Oslo, Norway (by invitation) I would like to hear about the treatment of dermatitis herpetiformis with diphenhydramine hydrochloride (benadryl®) Two patients in Norway whom I treated with benadryl® were relieved In 1 of the cases the disease was of six years' duration and in the other one-half year When benadryl® therapy was stopped, the itching became worse, the patients improved on resuming treatment with benadryl®

DR BERNARD APPEL, Lynn, Mass I questioned this patient about her reaction to benadryl® and she told me that it did not help her pruritus It did procure a good night's sleep and made her feel more relaxed but apparently did not relieve the itching I would agree with the diagnosis of dermatitis venenata due to rubber in the clothing The entire picture is consistent with that diagnosis, not only because of the definite, clear, smooth, symmetric pattern which corresponds to the articles of clothing worn that contain rubber but also because the rest of the eruption is consistent with it Contact dermatitis due to rubber from articles of clothing may produce generalized eruptions The presence of vesicles certainly does not contradict the diagnosis of contact dermatitis

DR JACOB H SWARTZ, Boston How often do you see clusters of scars in dermatitis from rubber?

DR BERNARD APPEL, Lynn, Mass Consequent reactions like crusting, follicular involvement, pigmentation and all the so-called "id" type of lesions depend, first, on the duration and, second, on the particular patient's sensitivity and intensity of reaction

Examination reveals an eruption limited to the dorsa of the hands and distributed over the region of the metacarpophalangeal joints The lesions consist of numerous solitary and grouped, milky white, hard nodules of uniform size, they are all 1 to 2 mm in diameter A few exhibit a faint narrow rim of surrounding erythema There is no tenderness now

A specimen was removed for histologic examination, and the diagnosis of "multiple epidermal cysts" was made Results of examinations of the chemical content of the blood, including calcium, cholesterol esters and fatty acids, were normal

DISCUSSION

DR MAURICE M TOLMAN The biopsy specimens were studied in several laboratories, all with the same diagnosis epidermal inclusion cysts, with some changes in the elastic tissue There was no evidence of xanthomatous infiltrate, or of colloid, as far as we know In the literature are reports of 3 such cases Ormsby presented one (Ormsby, O S Bullous Dermatitis [Pemphigus?], ARCH DERMAT & SYPH 28 246 [Aug] 1933) associated with pemphigus The lesions were in an area of the skin where pemphigoid lesions had healed, leaving these cysts In another instance, cysts came where there was vesiculation following exposure to the sun (Dietel, F *Dermat Wchnschr* 99 1637, 1934) The third patient had lesions at the sites of vesicles probably from dermatitis venenata We have all seen this occur in epidermolysis bullosa Apparently what takes place is a peculiar reaction to trauma The vesicular lesions heal entirely, and it is in the healing areas that one finds the origin of these epidermal cysts, representing some peculiar response of the tissue The patient is now improving, and we cannot find any reason for it, although she is now pregnant It might be that with the hormonal reaction there may be a nonspecific response She is about 50 per cent better

DR FRANCIS P MCCARTHY The histologic slides showed typical epidermal cysts which are seen so often in the lesions of epidermolysis bullosa One can explain the development of epidermal cysts in the latter disease but not so easily in a vesicular dermatosis on the basis of trauma

Tuberculosis Miliaris Disseminata Faciei Presented by DR FRANCISCO RONCHESE, Providence, R I

Berlock Dermatitis in the Form of a Band Across the Forehead Presented by DR G MARSHALL CRAWFORD, Boston

DISCUSSION

DR MAURICE J STRAUSS, New Haven, Conn I do not recall from the history that a perfume had been used, but, even if it had been, this should not be labeled Berlock dermatitis I would call it pigmentation following dermatitis The term Berlock dermatitis was coined to describe the disease in cases where perfume had been poured on and allowed to run down The word Berlock means pendant It is that particular configuration in which there is evidence of an irritating substance running down in streaks which should be kept as the original concept of Berlock dermatitis

DR WILLIAM B SWARTS, Greenwich, Conn The patient said that he had been employed as a bartender and that the eruption started in September I asked whether he served many Tom Collins drinks during the summer, because the use of lime oil is important The mechanism is the same as Berlock dermatitis except that the essential oil is sprayed over his face A patient of mine with dermatitis venenata of the face made the diagnosis herself and stated that she never got the

Multiple Epidermal Cysts of the Skin Presented by DR F RONCHESE, Providence, R I

A 14 year old white school girl, G deB , American-born of Portuguese parents, is presented with lesions which have been present on her face since birth They have not been observed to change appreciably with the passage of time She had

Fig 1—Multiple epidermal cysts of the skin The face of a 14 year old girl studded with milia, a few isolated lesions of keratosis pilaris and erythema

no hair anywhere until the age of 3 years, at that time a little began to appear on her scalp, and it developed slowly thereafter There were no eyebrows until the past few years, and no hair has developed elsewhere The patient has always been in good health There is no history of similar disturbances among other members of the family Negro ancestry was denied The patient seemed of normal intellect and was progressing well at school

3 0 cm One on the dorsum of the tongue was white on top, suggesting a secondary leukoplakic reaction The rest of the oral cavity was free of lesions

DR B J KENNEDY, Boston (by invitation) The woman was given urethane because of reports describing its use in leukemia and a few isolated carcinomas Urethane is called ethyl carbamate and is an ancient anesthetic for animals Haddon and Sexton (Influence of Urethane on Experimental Tumors, *Nature,* London **500** 157, 1946) found that phenyl carbamate and phenylurethane produced regression of mammary carcinoma in mice and Walker carcinoma in rats This led to investigation with urethane which produced the greatest effect, especially in the carcinomas There were scarring and decrease in the mitoses in the cells Another group from the same hospital began using urethane in human beings (Paterson, E , Haddow, A , Ap Thomas, I , and Watkinson, J M *Lancet* **1** 677, 1946) They tried it in 19 patients with myeloid leukemia, 13 with lymphatic leukemia and 13 with various types of carcinoma Among the last group only 4 (including patients with Hodgkin's disease and a salivary gland carcinoma) showed some regression of the tumor while the others had but little response The reaction in the patients with myeloid leukemia was striking In nineteen to forty-seven days the urethane produced a reduction in the white cell count of 20,000 or more cells It was found that this reduction of the white cells was chiefly in the neutrophils The hemoglobin did not seem to be affected, or the red cell count, and when the patients were given 100 Gm or more of the drug the hemoglobin rose an average of 27 per cent The patients with lymphatic leukemia showed a similar response but not as striking as did those with myeloid leukemia It was concluded that the urethane treatment of leukemia may be comparable to roentgen therapy The rise in hemoglobin, decrease in white cell count and reappearance of normal differential counts all followed the same pattern as would be expected with roentgen treatment Because of this and the close relation of mycosis fungoides to lymphomatous disease, urethane was given to this patient My co-workers and I plan to give it to a large series of patients to determine whether or not it is a drug that should be used in these cases This patient has been treated for almost two weeks, and the only response so far is perhaps some drying of the skin

DR JACOB H SWARTZ Have you read any reports citing granulocytopenia as a complication of this treatment?

DR B J KENNEDY, Boston (by invitation) Leukopenia develops in many of the patients If this reaction occurs, the drug must be withdrawn I have not heard of the occurrence of granulocytopenia

DR ARTHUR M SIMMONS What is the method of administration and dosage?

DR B J KENNEDY, Boston (by invitation) It is given orally, 1 Gm four times a day At present I do not believe that there is any definite dose that one can adhere to, we expect to try to increase the amount

Extensive Nevus Pilosus et Pigmentosus (von Recklinghausen's Disease?) Presented by DR G MARSHALL CRAWFORD, Boston

A Case for Diagnosis (Lupus Erythematosus? Tuberculosis Luposa?) Presented by DR ROBERT H GOLDFARB, Boston

Telangiectasia, Essential, Limited to Calves Presented by DR MAURICE M TOLMAN, Boston

C B , a 32 year old white housewife, is shown with changes on the backs of her legs which have been present for three and one-half years The patient first

follicular lesions on her forehead and similar changes on other areas where one finds Darier's disease I would suggest watching for the development of more evidence of keratosis follicularis

DR F RONCHESE, Providence, R I Dr Bernard Appel suggested to me the diagnosis of ulerythema ophriogenes This would be correct for the miliosis and the erythema, but there is no scarring The keratosis pilaris is limited to a few elements and the miliosis-erythematosis is not limited to the eyebrows but extends to the entire face However, this is an excellent suggestion, and an investigation will be made on the relation of this case to that rare entity which has been called ulerythema ophriogenes sive superciliare Tanzer, folliculitis rubra Wilson, keratosis pilaris rubra faciei Brocq and red keratosis pilaris Bazin This case is a good demonstration of the origin of milia in the hair follicle, the lesions eventually becoming keratosis pilaris, to be differentiated from the pseudomilia following epidermolysis bullosa or pemphigus and the miliary calcified sebaceous cysts It could be considered as a nevoid ectodermal defect

A Case for Diagnosis (Sinuses, Nodules and Ulcers of the Buttock Tuberculosis Colliquativa? Actinomycosis?) Presented by DR JACOB H SWARTZ, Boston

DISCUSSION

DR JACOB H SWARTZ, Boston I have two more tentative diagnoses to add symbiotic infection with Staphylococccus and Streptococcus, and dermatitis factitia plus infection I saw this man only once, and no laboratory work was done I will be glad to report on the case at the next meeting

DR FRANCIS M THURMON, Boston I suggest the diagnosis of dermatitis factitia It is asymmetric, and there was one lesion slightly stained, as though something had been applied, there were tiny white vesicles on the top

DR JOHN G DOWNING, Boston For three years I have been treating a man with a similar eruption, which started on his legs after contact with oil I have seen these eruptions on the arms following the same event Cultures from one patient showed that he had a synergistic combination of hemolytic Streptococcus and Staphylococcus

NOTE—A second biopsy specimen was subsequently removed from the patient's thigh, and a sinus tract found in the depth of the wound was curetted to obtain additional material for mycologic study Histologic observations were non-specific An extemporaneous preparation from curetted material revealed the "sulfur granules" of actinomycosis, and microscopic study showed the characteristic club-shaped formations Cultural studies were confirmatory

Scurvy Presented by DR GEORGE E MORRIS, Boston

E D, a 45 year old white man, formerly occupied as a welder, complained of an eruption *on the feet, legs and thighs of six weeks' duration The first lesion* appeared on the left thigh as a red scaly patch Three weeks ago the lower extremities rapidly erupted with dark spots all over the legs The patient has consumed considerable quantities of alcohol, and his diet was distinctly inadequate

At this time numerous fading purpuric blotches may be seen on the lower portions of the patient's legs and the dorsa of his feet The remainder of the lower extremities, the buttocks and lower portion of the trunk show a sparse eruption of small, brownish, scaly patches from 0 5 to 1 5 cm in diameter

York State J Med 46 2147 [Oct 1] 1946) who used with success in dyskeratotic dermatoses triolein ozonide, which is formed in olive oil on ozonization

DR NEVILLE KIRSCH, Hartford, Conn (by invitation) Sharlit has used ozonides in oil By rubbing in the oil four times daily his patients succeeded in eliminating keratotic lesions It has also been employed by MacKee The product may be obtained from G F Harvey & Company of Saratoga Springs, N Y, and must be refrigerated Twenty per cent of the ozonide mixture is incorporated in an appropriate base and rubbed in four times a day for six to eight weeks

DR WALTER F LEVER, Boston I have had no experience with ozonides, but I suggest treatment with 2,3-dimercaptopropanol (BAL) Since in this patient the arsenic preparation was given only two years ago, there may still be some arsenic remaining in her tissues, and it might continue to form keratoses BAL is effective in liberating organic arsenic from tissue

Dermatitis Herpetiformis (Contact Dermatitis from Rubber?) Presented by DR CARL A DAHLEN, Boston

T B, a 23 year old white girl, displayed an eruption of two years' duration, affecting the forearms, scalp, trunk and buttocks The first lesions appeared on the forearms in the form of vesicles At some later date the scalp became affected Lesions developed on the back and buttocks about a year ago Itching and burning have been severe, the patient claimed to be exhausted at times from these symptoms

On examination this young woman revealed a symmetric eruption affecting the scalp, forehead, elbows, dorsal aspects of the forearms, shoulders, scapular areas, lower part of the trunk and buttocks On the back is a transverse band of clear skin at the level between the brassiere and girdle areas The primary lesions are grouped vesicles and papules with crusted excoriations and pigmented scars These changes are most pronounced on the elbows, shoulders and hips The lines demarcating the clear zone across the back are rather sharp Both the upper part of the back and the girdle area below reveal a mild diffuse erythema, and there is a minimal amount of fine branny scaling on these regions On the upper part of the back there are three moderately distinct rectangular patches, which stand out from the previously defined changes One is seated transversely across the middle part of the back, the other two are vertically parallel to each other on the midscapular regions These patches are approximately 5 by 15 cm in size and display a perceptible thickening with more scaling than the surrounding skin

Results of an examination of the urine and a hemogram were normal Treatment included use of diphenhydramine hydrochloride (benadryl®) 0 05 Gm three times daily for five weeks, followed by sulfapyridine, 0 5 Gm, twice daily for two weeks Two suberythema doses of ultraviolet rays were given prior to the sulfonamide drugs There had been temporary improvement from these measures

DISCUSSION

DR FRANCIS M THURMON, Boston I agree with the diagnosis of dermatitis herpetiformis If sulfapyridine were used in larger dosage, it would be more effective

DR GEORGE SCHWARTZ, Boston I disagree This is contact dermatitis due to rubber inserts in her brassiere and girdle I had the patient put on her girdle, and the lower portion of the eruption formed a complete outline of the garment The dermatitis is now becoming generalized

Leukoplakia of the Penis. Presented by DR JOHN G DOWNING, Boston

J F, a 65 year old white man of Irish birth, a retired elevated railway conductor, is presented with the complaint of soreness and cracking of the prepuce for about two months The patient had applied only petrolatum This afforded no relief, and the condition had become steadily worse

Examination reveals a distinct thinning of the skin of the prepuce and also of the glans penis There is a constricting sclerotic band about 2 cm proximal to the free edge of the prepuce, this has been partially relieved by biopsy, and at that point where the biopsy specimen was taken there is a small crust The remainder of this band is characterized by the appearance of whitish plaques and streaks with several erosions and fissures

The diagnosis from histologic study was reported as leukoplakia There has been no treatment

DISCUSSION

DR FRANCIS P MCCARTHY, Boston Leukoplakia resembles kraurosis in the aged in the sense that there are interstitial changes and leukoplakia and erosion

DR BERNARD APPEL, Lynn The diagnosis of kraurosis of the prepuce was considered The microscopic examination ruled that out, because it did not show typical changes of kraurosis or atrophy

DR FRANCIS P MCCARTHY, Boston The depth of the biopsy specimen may be misleading A deep section is essential and special connective tissue stains are required in order to rule out kraurosis In spite of the histologic changes, I feel that this is kraurosis of the prepuce

DR WALTER F LEVER, Boston I would oppose the diagnosis of kraurosis The histologic picture of kraurosis is characterized by atrophy of the epidermis and degeneration of the collagen In this case there was neither The epidermis was acanthotic, and there was considerable hyperkeratosis The biopsy specimen extended a fair depth into the connective tissue, and it showed no evidence of degeneration There were numerous dilated capillaries and a chronic inflammatory infiltrate There was no evidence of carcinoma The histologic picture is consistent with senile keratosis or leukoplakia

DR FRANCIS P MCCARTHY, Boston In kraurosis there may be areas of atrophy and also leukoplakia with both hyperkeratosis and acanthosis

DR JACOB H SWARTZ, Boston I agree

DR JOHN G DOWNING, Boston There was no evidence of kraurosis or atrophy The skin was infiltrated, fissured and leukoplakic in appearance It probably would go on to cancerous degeneration if neglected This patient can be cured by excising the area affected

Leukoplakia of the Tongue, Buccal Mucosa and Lips, Syphilis Presented by DR F RONCHESE, Providence, R I

A D, a 38 year old white man of American birth, a truck driver, for the past three years had noted white patches on his tongue and lips and on the inside of his mouth The anterior portion of the tongue was raw for much of this time and was somewhat tender, but there was otherwise little discomfort Shortly after the appearance of these lesions the patient was found to have repeatedly positive serologic reactions to tests for syphilis No history referable to the date of infection was obtainable, previous genital or cutaneous lesions were denied No other relevant data were obtained The patient smoked from eight to ten cigars daily

DR JOSEPH GOODMAN, Boston I think that we are going far afield when we call this a contact dermatitis Let us assume, with Dr Schwartz, that this eruption corresponds exactly to the rubberized areas of the girdle It has spread to the forehead, scalp and elbows In contact dermatitis severe enough to produce a widespread eruption one must also expect a local extension I cannot conceive of a dermatitis of this sort spreading so widely without becoming generalized on the trunk I am sure that if these lesions were not in the area touched by her girdle, there would be no doubt about dermatitis herpetiformis

DR JOHN G DOWNING, Boston Two months ago this girl presented a classic picture of dermatitis herpetiformis, with the characteristic symptom of burning She showed grouping, pigmentation and atrophic scarring Today there is unquestionably a superimposed contact dermatitis which might be due to the elastic in the straps of her brassiere

DR CARL A DAHLEN, Boston There was considerable relief from treatment with benadryl,® but the patient failed to return The next time we saw her she had a recurrence I decided to give sulfapyridine, and it was prescribed in a dose of 0 5 Gm twice a day, but she still did not report back as instructed If she were cooperative, I might have obtained better results by increasing the sulfapyridine

DR FRANCIS P MCCARTHY, Boston This girl had a very interesting tongue She showed linear filiform papillae along the margins and beneath these areas were tufts of white hairlike papillae I made a diagnosis of depigmented congenital defect of the filiform papillae Some textbooks indicate that there are oral lesions in dermatitis herpetiformis I have never observed them, although I have been searching for years Has anyone here seen lesions in the mouth in dermatitis herpetiformis?

DR FRANCIS M THURMON, Boston I have seen 2 cases, one was shown to me in Chicago and the other was presented by me at a meeting of this Society

DR WALTER F LEVER, Boston I have seen 1 patient His eruption responded well to the usual doses of sulfapyridine, 2 to 3 Gm a day There was no doubt about the diagnosis

Lichen Planus of the Eyelids and Buccal Mucous Membranes Presented by DR WILLIAM J MACDONALD, Boston

Lichen Sclerosus et Atrophicus (Generalized) Presented by DR JOSEPH GOODMAN, Boston

DISCUSSION

DR JOSEPH GOODMAN, Boston This 43 year old woman has been followed in the clinic for six months At the start there was a hyperkeratotic follicular eruption characterized by small horny spicules She had alopecia when first seen, and this has extended since then It was thought at first that this was a vitamin A deficiency, but the vitamin A level and carotene level were normal In spite of that she received 200,000 units of vitamin A daily for a period of two months, during which time the eruption became worse The patient was then admitted to the hospital, and a biopsy was performed on the scalp lesions Those on the arms began to look like lichen planus and others have too, but at the same time many of the horny spicules seen when she was first observed in the clinic have persisted The picture presented today corresponds closely to the description of the disease called "lichen planopilaris" by Sachs and De Oreo (ARCH DERMAT & SYPH **45** 1081 [June] 1942)

DR FRANCIS P MCCARTHY, Boston That is a reasonable explanation, and the factitial element in this case may explain the unusual findings

Psoriasis, Keloids Following "Injections" Presented by DR LEO KORETSKY, Chelsea, Mass

A Case for Diagnosis (Erythema Multiforme Exudativum? Bullous Impetigo?) Presented by DR GEORGE SCHWARTZ, Malden, Mass

DISCUSSION

DR MILDRED L RYAN, Brockton, Mass I think that this 3 year old child has dermatitis medicamentosa She has had frequent attacks of asthma Has she been given any iodides or bromides?

DR GEORGE SCHWARTZ, Malden, Mass I saw this girl ten days ago At that time she presented bullae of ½ to ¾ inches (1 to 2 cm) in diameter, arising from normal skin They were on the arms, legs, abdomen and neck, there also were six or eight vesicles on the scalp I found nits and thought that she had bullous impetigo I have not seen her since then, and today she shows a different picture, one would think that she was another patient

DR S J MESSINA, Boston I think that this is a case of Loeffler's syndrome She had a high eosinophilic count and a history of asthma, which are characteristic of that disease There may or may not be an eruption which can suggest erythema multiforme I think that Loeffler's syndrome is a strong possibility in this case

DR JOHN G DOWNING, Boston I agree with the diagnosis of Loeffler's syndrome Recently I saw a patient with a history of asthmatic attacks, mottling on the chest and an eruption resembling erythema perstans on the chest, the blood picture showed a high eosinophil count

Dr Francis M Thurmon, *President*

Dr G Marshall Crawford, *Secretary*

New Haven, Conn, Oct 8, 1947

A Case for Diagnosis (Xanthomatosis?) Presented by DR MAURICE J STRAUSS, New Haven, Conn

E C, a 2 year old white girl, acquired a solitary lesion on the right cheek at about the age of 4 months This slowly increased in size, and gradually a few similar lesions developed around the original one The latter attained a size of 9 by 6 mm before excision six months ago They have been asymptomatic

On the right cheek there is a group of six small, solid, slightly elevated brownish red nodules each about 4 or 5 mm in diameter

Histologic examination revealed only a chronic inflammatory reaction

DISCUSSION

DR LEON BABALIAN, Portland, Me Although there is no regional enlargement of lymph nodes in this case, it is difficult to rule out lupus vulgaris

DR ALFRED HOLLANDER, Springfield, Mass My opinion is that these lesions belong to the group of localized xanthoma I did not study the slide too well, but the section did show some foam cells

There is a luxuriant growth of kinky hair on the scalp and the facial conformation is Negroid The face is reddish pink The skin thereon appears granular and feels slightly rough It is entirely covered with densely packed miliary lesions of 0 5 to 1 0 mm diameter, these are pearly white and smooth Diascopic examination shows complete blanching of the lesions No telangiectases can be observed The patient's eyebrows are sparse, scaly and also studded with milia The remainder of her skin exhibits no hair The lateral aspects of the arms and thighs reveal a sparse eruption consistent with keratosis pilaris, and a few isolated lesions on the face are similar in type No scars can be found anywhere

The Hinton reaction of the blood was negative Results of examination of the urine were normal A hemogram was normal with the exception of a leukocyte

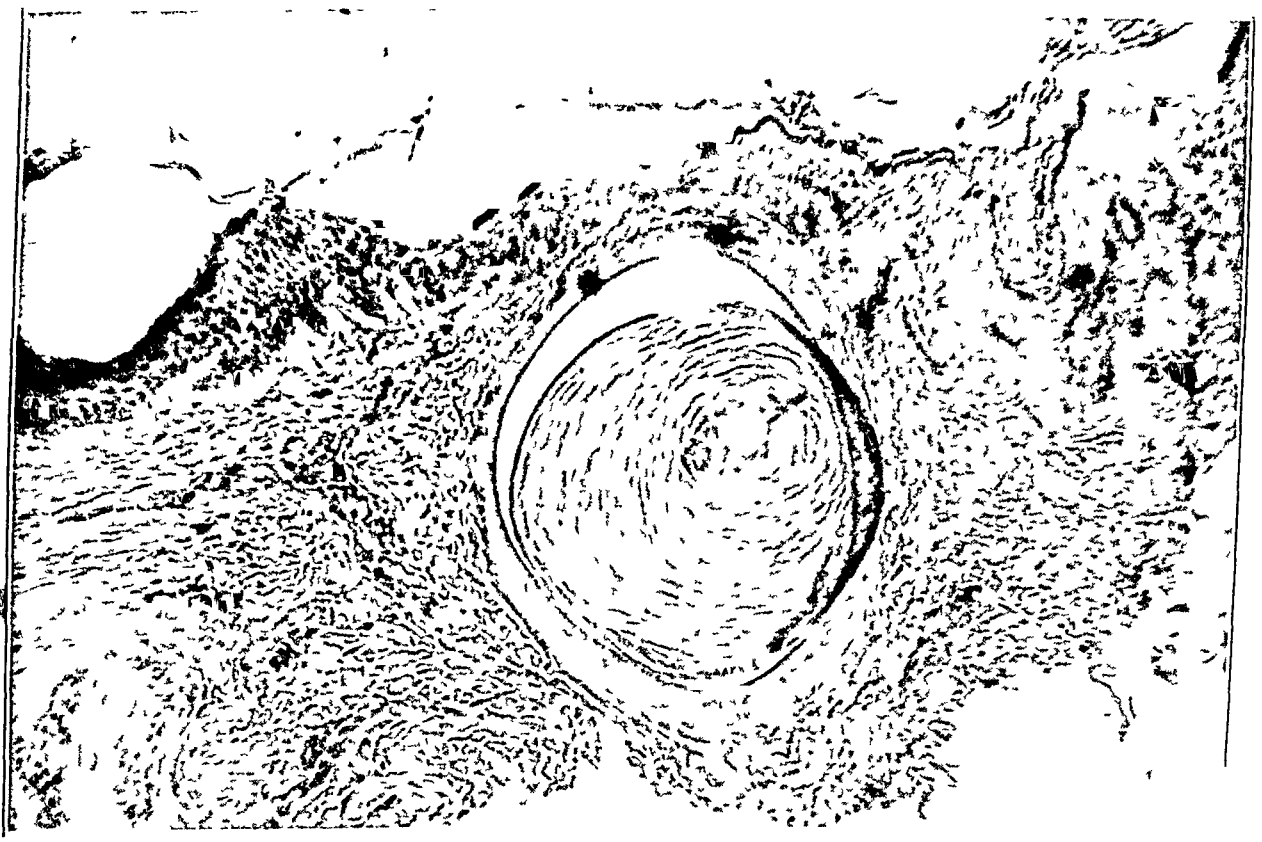

Fig 2—Multiple epidermal cysts of the skin Histologic section showing epithelial cysts

count of 10,750 cells per cubic millimeter The nonprotein nitrogen and glucose content of the blood were normal Histologic examination of a biopsy specimen revealed a moderate degree of hyperkeratosis There were cystic cavities about 0 2 mm in diameter just beneath the epithelium, these were lined with squamous epithelium and filled with a laminated keratotic mass No treatment had been administered until the past two months, during which time the patient has taken 200,000 units of vitamin A daily, there has been no appreciable improvement

DISCUSSION

DR JACOB H SWARTZ, Boston Although I am in accord with Dr Ronchese's diagnosis, I should like to point out that the patient had definite hyperkeratotic

treatment was discontinued Tripelennamine hydrochloride (pyribenzamine hydrochloride®), 50 mg four times a day, is of slight value at this time

DISCUSSION

Dr Bernard Appel, Lynn, Mass I think that the case is clinically typical of dermatitis herpetiformis and accept the diagnosis as presented The patient said urticarial reactions were so severe that he was completely covered with wheals Since sulfapyridine produces such a reaction, I suggest that tripelennamine hydrochloride be used in appropriate doses, I should prescribe 600 or 800 mg daily A patient with dermatitis herpetiformis who took sulfapyridine with fairly good results was recently given diphenhydramine hydrochloride (benadryl hydrochloride®) for a comparison She noted more lasting relief and recession of the lesions than with sulfapyridine One expects some trouble from sulfonamide drugs, and it is much safer to use tripelennamine or diphenhydramine in large doses

Dr Maurice M Tolman, Boston Since 1938 I have had under personal observation 3 patients with dermatitis herpetiformis who have taken sulfapyridine continually without reaction, and it controlled their disease I am a little afraid of continuing its use indefinitely We decided to try diphenhydramine and tripelennamine in doses of 600 mg daily in carefully controlled patients in the hospital but observed no relief from pruritus or diminution of the lesions We then administered sulfapyridine, there was immediate response, and remission took place

Dr Joseph Goodman, Boston On the other side of the picture, I should like to mention a patient who took sufficient sulfapyridine to produce a blood level of 7 mg per hundred cubic centimeters with but little effect on the dermatitis herpetiformis That patient has responded better to 400 mg of diphenhydramine daily than to the large doses of sulfapyridine One must thus conclude that some patients do better with one drug and some with the other I cannot maintain that sulfapyridine controls the disease in all patients with dermatitis herpetiformis, the same is true of tripelennamine and diphenhydramine

Dr Neville Kirsch, Hartford, Conn Some physicians in general practice have treated dermatitis herpetiformis with nicotinic acid

Hemangiolymphangioma of Tongue Presented by Dr Maurice J Strauss, New Haven, Conn

Sarcoidosis of Skin Presented by Dr E Myles Standish, Hartford, Conn

Adenoma Sebaceum Presented by Dr Maurice J Strauss and (by invitation) Dr Louis O'Brasky, New Haven, Conn

H M is a 12 year old white school girl About two months after she was born, her parents first noticed thickening under the toe nails and finger nails At the age of 7 years, papules appeared on the face Both parents are living and well and have no lesions of the skin although both are mentally defective One brother has a speech defect and is classified as mentally defective but shows no cutaneous abnormality Two brothers and two sisters are mentally and physically normal The patient herself is mentally normal

On the face there are numerous groups of small discrete white papules, symmetrically distributed over the forehead, on the sides of the nose and on the zygoma All the nails of the hands and feet are thin, soft and discolored, especially the nails of the great toes, and their growth is retarded There are brown fibrotic

The result of the tourniquet test was positive A hemogram was normal, including a count of the thrombocytes The patient has been given 2 quarts (about 2 liters) of orange and grapefruit juice daily for the past four days

DISCUSSION

DR WALTER F LEVER, Boston I suggest the diagnosis of Majocchi's disease In scurvy one has massive bleeding into the skin Here they are hemorrhagic punctate dots and erythema, as are commonly seen in Majocchi's disease

DR JOSEPH GOODMAN, Boston I agree that the lesions resembled Majocchi's disease, but in my opinion the patient has symptomatic purpura Whether or not he had scurvy could have been ascertained by a vitamin C determination, which was not on the record Since the treatment it would be impossible to say whether he had scurvy Follicular hemorrhages are characteristics of that disease

DR GEORGE E MORRIS, Boston When this man was seen last week he had the follicular hemorrhages which are typical of scurvy One may find large ecchymoses, but it is typically a punctate hemorrhagic disease Last week the result of a tourniquet test was strongly positive The patient was given a diet rich in vitamin C against my orders, and the result of the tourniquet test is now negative The eruption is disappearing That is not typical of Majocchi's disease

Dermatophytosis of the Extremities, Due to Trichophyton Purpureum

Presented by DR SEYMOUR J WHITE, Lawrence, Mass

An intradermal injection of 0 1 cc of Lederle's diagnostic trichophytin extract (1 30) gave rise to an immediate wheal reaction, within ten minutes it measured 1 5 cm in diameter, and numerous pseudopods soon appeared This reaction remained about twelve hours and left a persistent, erythematous, scaly patch, the result of a control injection of isotonic sodium chloride solution was negative Scales removed from the right palm and planted on Sabouraud's medium produced a growth identified as Trichophyton purpureum A biopsy specimen obtained from the left knee exhibited only nonspecific inflammation A number of fungicidal remedies have been applied for prolonged periods of time without response

DISCUSSION

DR JACOB H SWARTZ, Boston I suggest that the mycologic diagnosis be held in abeyance until the culture is more characteristic These lesions do simulate those seen with infection by the organism of Trichophyton rubrum (or T purpureum), but it might be Trichophyton gypseum

DR WALTER F LEVER, Boston Dr Swartz, do I understand that T rubrum or purpureum does not cause sensitization?

DR JACOB H SWARTZ, Boston That is correct, and I would not pay much attention to the immediate reaction A diagnosis should not be made on the cutaneous test alone, and I cannot do so on the strength of the culture as yet

DR FRANCIS P MCCARTHY, Boston Is this organism a possible contaminant or a true pathogen? I should like to know whether it is found on the skin normally

DR JACOB H SWARTZ, Boston I have never seen it as a contaminant

DR JOHN G DOWNING, Boston My co-workers and I cultured 100 specimens of normal skin of patients who had never had a fungous infection Specimens were taken from the scalp, the corners of the mouth, between the toes and the soles Pathogenic fungi were found in 2 cases, neither T purpureum nor Monila albicans (Candida) was isolated

Multiple Idiopathic Hemorrhagic Sarcoma of Skin Presented by DR M J MORRISSEY and DR H S REYNOLDS, Hartford, Conn

Aphthous Stomatitis Presented by DR MAURICE J STRAUSS, New Haven, Conn

Alopecia Cicatrisata Presented by DR MAURICE J STRAUSS, New Haven, Conn

Acarophobia Presented by DR ELLWOOD C WEISE, Bridgeport, Conn

Blastomycosis of the Skin Presented by DR MAURICE J STRAUSS and (by invitation) DR HARRY SIGEL, New Haven, Conn

H M, a 23 year old white electrician, first noticed a "pimple" on his left shoulder about a year ago For six months immediately preceding the development of this lesion he lived in Connecticut From September 1945 to February 1946 he was in Korea and from March to September 1945 in Okinawa Prior to that he lived in Idaho While in Okinawa, some "sores" developed on the back of his neck and on the extensor surfaces of both hands These healed spontaneously within about six weeks The lesion which marked the onset of the present condition grew slowly and progressively As the border extended, the central portion partly healed

There is now a large lesion on the left shoulder, about 18 cm long and 10 cm wide The border is circinate, bluish red, raised, rolled and indurated The marginal elevation slopes gradually toward the center of the lesion The border is most prominent at its medial edge, and there it appears somewhat verrucous Several portions of the margin are tender and exude small drops of pus on pressure The lateral edge of this lesion is flatter and more cicatricial

Direct microscopic examination of exudate from the lesion showed round, thick-walled, budding cells Cultural studies yielded a typical growth of Blastomyces dermatitidis hyphal with chlamydospores at room temperature and budding cells when incubated There has been no treatment administered

DISCUSSION

DR JACOB H SWARTZ, Boston I saw the slides and culture mounts and agree with the diagnosis of blastomycosis The culture was difficult to identify, as are all cultures in such cases The one grown at room temperature showed the hyphal type of growth with chlamydospores The one grown on Sabouraud's medium at incubator temperature exhibited the typical budding cells which are characteristic of Blastomyces Clinically the lesion was also compatible, with wartlike projections from the border The question at present is how to cure it I suggest a combination of sulfonamide drugs and roentgen rays Beyond that, I suggest ethyl iodide by inhalation Excision would be satisfactory if the condition is not systemic It is advisable to have a roengen examination of the chest and other structures that are liable to be involved, together with a complete neurologic examination and study of the spinal fluid The scar from a previous vaccination also shows early lesions of blastomycosis

DR ADRIAN SCOLTEN, Portland, Maine Must one go out of the country to acquire this disease?

The distal half of the dorsal aspect of this man's tongue is almost completely denuded of epithelium Within this area there are numerous small, white, infiltrated islands and some atrophic scarring The entire distal half of the tongue appears somewhat shrunken and atrophic, the margins are slightly elevated and are marked with alternate red and pearly gray striations The patient's lips and buccal mucosa also exhibit scattered small plaques of white atrophic tissue

Treatment has been carried on by the patient's family physician It consisted of fifty-five injections of bismuth salicylate and thirteen of oxophenarsine hydrochloride (mapharsen®) between May 1943 and October 1945 The dosage of these treatments was not known, there had been no clinical improvement The patient was smoking less during that time In March 1947 3,000,000 units of penicillin in oil and wax were administered, without detectable effect on the oral changes

The Hinton and Kahn reactions of the blood had both remained consistently positive up to the time of presentation Histologic examination of a biopsy specimen taken from the tongue revealed the following changes consistent with leukoplakia, acute ulceration and inflammation of the mucosa, with no evidence of malignancy

DISCUSSION

DR FRANCIS P MCCARTHY, Boston The erosion on this patient's tongue came on suddenly, and the ulceration has continued for three years As a result of inadequate treatment for syphilis there developed a smooth atrophy suggestive of glossitis luetica atrophica The failure of the ulceration to heal may be explained by interstitial connective tissue changes associated with limited blood supply from an old endarteritis I have recently studied syphilitic glossitis in postmortem specimens wherein interstitial sclerosis associated with decided narrowing of the lumen of arteries and atrophy of the overlying papillae are constantly found The granulation tissue as seen in this case does not become malignant, but the leukoplakic lesions in the periphery of the lesion may show a malignant tendency

DR JOHN G DOWNING, Boston When I first saw this man's tongue I was impressed by the sharp outline of the granulations and the intervening islands of leukoplakia I ordered two biopsies to eliminate malignancy, the diagnosis from both specimens was chronic inflammation I might suggest a diagnosis of stomatitis factitia I have seen 3 cases in which this condition was proved to be self-inflicted This man has syphilis, and I believe that he has been applying some strong chemical to his tongue to remove the previous leukoplakia

DR FRANCIS M THURMON, Boston Around the denuded areas there is definite leukoplakia of the tongue I think that the prognosis is serious, because once cancer of the tongue develops in a patient with tertiary syphilis there is no treatment that is successful

DR FRANCIS P MCCARTHY, Boston I am interested in what Dr Downing said because it seems unusual to see granulation continue so long without healing The blood supply is greatly diminished, and that may be a factor Why anyone should inflict a lesion of this kind on his own tongue is difficult to understand without some compelling motive such as the collection of compensation The patient told me that it developed overnight

DR F RONCHESE, Providence, R I If the changes on this man's tongue are regarded as potentially malignant, the entire surface should be removed with the coagulating loupe

DR JOHN G DOWNING, Boston Syphilis is in the background of this disease of the tongue, aggravated by a therapeutic attempt to cure it

Necrobiosis Lipoidica Diabeticorum Presented by DR MAURICE M TOLMAN, Boston

Basal Cell Epithelioma, of Nose, Forehead, Left Eyebrow and Left Upper Eyelid Presented by DR JOHN G DOWNING and (by invitation) DR HARVEY B ANSELL, Boston

Tinea of Face (Microsporum Fulvum), Neurodermatitis Circumscripta of Wrist Presented by DR SEYMOUR J WHITE, Lawrence, Mass

Chronic Pemphigus of Eye with Cicatrizing Lesions of Skin Presented by DR BERNARD APPEL, Lynn, Mass

Frambesia Tropica (Yaws) Presented by DR JOHN G DOWNING, Boston

E R, an 8 year old Negro girl, has had lesions on the right heel and left gluteal fold for the past ten months The first lesion to develop was on the right sole, it appeared in December 1946 At that time the child resided in Jamaica, British West Indies, where a diagnosis of yaws was made Treatment consisted of one injection of a bismuth preparation and three of arsphenamine, and the lesion healed Another appeared on the right heel in July 1947, and the patient moved to Boston a month later She was first seen in the Boston City Hospital clinic in September 1947, and by that time another lesion had developed in the left gluteal fold There has been good response to therapy

Examination of the right heel when first seen three months ago revealed a raised, crusted, nontender granuloma, 1 5 by 1 5 cm This was surrounded by a 2 cm area of induration and scaling A similar, but smaller, lesion was present in the left gluteal fold but with less induration At this time there is little to be seen on either area The skin is slightly blacker than this moderately dark negroid integument, and a very indistinct trace of induration can be palpated

A dark field examination of material obtained from the lesions revealed organisms indistinguishable from Treponema pallidum The Hinton and Kahn reactions of the blood were positive on two occasions The hemoglobin content and red cell and white cell counts of the blood were normal, a differential smear revealed 48 per cent polymorphonuclear leukocytes, 42 per cent lymphocytes, 8 per cent monocytes and 2 per cent eosinophils Treatment consisted of intramuscular injections of penicillin, a total of 3,350,000 units was administered

Frambesia Tropica (Yaws) Presented by DR JOHN G DOWNING, Boston

D R, a 5 year old Negro boy, a brother of the preceding patient (E R), has lesions on the left heel and the buccal mucous membrane The first change appeared on this little boy's knee after an injury in April 1947 which failed to heal The ulcer was diagnosed as yaws and treated with three injections of a bismuth preparation plus seven of arsphenamine During the time of treatment several other lesions appeared on both legs, but all were healed by the time therapy was terminated He also came to Boston in August 1947 There was no further trouble

DR E MYLES STANDISH, Hartford, Conn I recall that about fifteen years ago I saw an almost exact counterpart of this lesion as far as color and induration are concerned, it proved to be lupus vulgaris

DR JOSEPH MULLER, Worcester, Mass I also thought of tuberculosis, but with pressure under a glass slide there was absolutely no sign of the typical apple jelly color that lupus vulgaris should show

DR ELLWOOD C WEISE, Bridgeport, Conn Although the light was poor where this little girl was shown, I thought that I could see a number of comedos in the affected area I have seen cases of precocious acne accompanied with chronic granulomatous lesions which were similar in appearance

DR BERNARD APPEL, Lynn, Mass I had the same first impression, but then I moved the baby into better light and saw that these pinpoint black dots were not comedos but little deposits of pigment My next feeling was that this was a nevus xanthomatosus I did not see the slide, but I do not consider the presence of foam cells essential

DR G MARSHALL CRAWFORD, Brookline, Mass There were definite small pigmentary deposits The possibility of a sebaceous nevus came to mind in view of the yellowish red color and firm consistency of the nodules I searched the section for foam cells but saw only a number of large pale reticulated structures which suggested portions of sebaceous glands cut at the edges

DR JACOB H SWARTZ, Boston This lesion may be given several different names It does not matter whether it is called nevus comedonicus or a sebaceous nevus, it falls into the same group I do not believe that a foam cell will ever be found

Granuloma Annulare Presented by DR MAURICE J STRAUSS, New Haven, Conn

Keratosis Follicularis Presented by DR ALBERT LEVENSON, Bridgeport, Conn

Dermatitis Herpetiformis Presented by DR CHARLES N SULLIVAN, New Britain, Conn

E S, a 42 year old white printer, first had severely pruritic lesions on the back of the left thigh four years ago, the eruption slowly spread and became generalized There have been several remissions and exacerbations, but the eruption has never completely cleared

There are groups of crusted papules, each lesion about 2 to 3 mm in diameter, scattered profusely over the trunk and extremities On the cheeks there are vesicles, some recently abraded and crusted There are many macular scars with pigmentation

Examination of the blood revealed nothing abnormal except 11 per cent eosinophils Microscopic examination of a biopsy specimen, reported by Dr Wilbert Sachs, of New York, showed the vessels of the middle and upper parts of the cutis dilated and the walls slightly thickened There was a perivascular infiltrate of small round cells and wandering connective tissue cells There was moderate interstitial edema in the upper part of the cutis The epidermis was regularly acanthotic, with an impetiginized cavity which had partially broken through at one point

Sulfapyridine relieved the pruritus but produced urticaria Sulfadiazine and roentgen ray treatment produced a remission, but the eruption recurred when this

finally sent back to the United States for that reason The lower lip
nvolved while he was in the South Pacific, but the condition has never
evere as on the upper lip

e present time the external appearance of the lips is grossly normal except
edema of the upper lip The inner aspect of the latter reveals intense
involving the two center fourths of the lip There is a depression
